It would be unwise to dogmatise in this matter of the nature of the fatty acids capable of production by an oxidation process. Results already published reveal several inconsistencies. The production of such straight-chain acids as stearic, palmitic, arachidic and oleic, as well as others of the odd carbon atoms series in apparently good yield, has been variously reported, and it can scarcely be believed, in the light of recent work on the composition of paraffin wax and petroleum hydrocarbons, that the starting materials were preponderatingly straight-chain in nature.

If, then, further research shows the economic impossibility of fractionating mineral oil so as to obtain normal paraffins or suitable unsaturated hydrocarbons, and if it be proved that poly-nuclear and forked chain hydrocarbons cannot yield straight chain acids of a sufficiently high molecular magnitude, even a definitely controlled oxidation can only lead to an acid or acids differing essentially from the fatty acids now available to industry. The physical properties of the olein grades used in the textile industry and of the stearin employed in candlemaking are definite, and artificial acids will have to approximate very closely in their physical properties to those found by experience to be most satisfactory. Similarly, in the soap industry, if it be conceded for the moment that fatty acids will be accepted in place of the glycerides now almost universally employed, the many eutectic mixtures of natural fatty acids and the physical properties which govern surface tension, emulsive and absorptive phenomena can probably not be imitated without a wide range of artificially produced acids with which to work. The considerable research which was essential before the acids of a simple hydrogenated oil could be applied in soap and candle manufacture may be noted as an approximate parallel.

Moreover, as indicated above, the fat industry demands far more glycerides than acids, and, assuming economic esterification possible, the nature of the glycerides or esters produced would probably be widely different from that of natural fats and oils. (The question of mixed glycerides cannot be discussed in short space, and must be left with a mere notice.)

It is difficult to imagine that a synthetic glyceride mixture, prepared from non-straight-chain acids, would approximate in its drying properties to linseed oil, for instance, unless a vast number of experiments were made, and a large number of fatty acids were available for esterification.

Difficulties, however, exist only to be overcome, and the application of scientific research to the above problems is the only manner by which success can be won. It is not merely a question of changing a terminal methyl group of a simple normal paraffin into a carboxy group, as was vaguely imagined at first, but demands a wealth of study upon mineral oil constitution, before a real start can be made. If economic reasons prevent the adoption of the process, the value of the research can never be lost. Hydrocarbon investigation is already proving fruitful in connection with lubrication problems, whilst oxidation of low grade oils is leading to the production of an "oxidised kerosene," which is claimed to be of great value in kerosene engines, and for the prevention of "knock" in the internal combustion engine generally. The stimulus to the study of preferential catalysis and the increase in our knowledge of the relationships between constitution and physical constants of fatty acids, which must necessarily follow a scientific attempt to solve the problem of fatty acid production from mineral oils, will benefit science and industry even if the original problem remain unsolved technically.

THE SUPPLY OF NATURAL OILS AND FATS

The relation between the supply of and demand for natural oils and fats, and the extent to which production costs can be lowered in case of competition, are questions which must be touched upon when discussing the economics of artificial fatty acid and fat manufacture.

In normal times the supply of natural oils and fats is quite equal to the demand, and it can be increased when required to an almost illimitable extent. It will only be possible here to discuss briefly the two following phases of this matter, namely:—

1. The examination of some figures of increased production of oil seeds, etc., in various countries.
2. The indications that specialised attention to plant culture will be able to reduce production costs considerably by reason of much greater oil yields.

No account will here be taken of the large supplies of animal fats—butter, lard, tallow, etc.—nor of marine animal oils—whale, seal, herring, sardine, menhaden, yellow tail fish oil, etc. The potentialities of yeast fat can but be referred to, and the biological fermentation of sugar to produce fat, and the interesting experiments at St. Andrews on the utilisation of non-carbohydrates in this biological synthesis must be left with mere mention, although they represent the possibility of an alternative "artificial" fat process.

Oil Seed Production

The production of oils, seeds and nuts is recovering to pre-war dimensions, and the total export figures for the various countries in respect of copra, palm kernels, cotton seed, arachis, sesame, maize, poppy, mustard, linseed, hemp, rape, soya bean, castor and non-classified seeds, in the years 1913, 1918 and 1919 were respectively seven, three and five million tons. These large figures do not include large quantities of cotton seeds crushed in the country of production—for instance, 400,000 tons in the United States—nor the home consumption, say, of soya bean, the 1919 production of which in Manchuria was 2·3 million tons.

It may be interesting to quote figures of increased production, as indications of the way in which the supply of oil seeds can be increased in case of necessity. Thus, the cottonseed crop of the U.S. has increased fourfold in less than fifty years, and linseed almost ninefold. Canadian linseed production has increased eighty-fold in thirty years, whilst the areas under cultivation in British India and the Argentine have increased in fifty years from 100 acres to 3·6 million acres. Arachis production in Senegal is a dozen times that fifty years ago, and Indian arachis is grown three times as extensively as in 1910. Similar figures might be quoted with respect to arachis and soya bean in the United States, and the cultivation of the latter product in China has increased tenfold in the last twenty years. Ceylon is exporting almost two hundred times as much copra as she did sixty years ago, and the Dutch East Indies have risen rapidly to a production of 400,000 tons per annum of coconut oil.

Finally, the West African palm oil and palm kernel production shows similar increases. Nigerian outputs of palm oil and palm kernels have risen in the period 1913-1918 from 83,000 to 86,000 tons, and from 174,000 to 205,000 tons respectively, whilst the total West African output is about 130,000 tons of palm oil and 400,000 tons of palm kernels.

Statistics are often meaningless, especially those referring to abnormal periods, such as the war years covered in the last figures quoted, but the whole series, selected from a mass of collected information, serves to prove the possibility of crop increases in suitable countries. The time-war production of castor seed in America, India and Australia also indicates the possibility of growing oil seeds extensively whenever necessary.

The potential value of tropical and South America as an oilseed producing locality must not be forgotten, when the better known countries—West Africa, the Indies, etc.—are being discussed.

Scientific Cultivation

A growing interest is being taken in scientific cultivation, and the experience of many colonial departments of European Governments is proving that much greater yields of palm and coconut products are obtained from cultivated trees, as compared with the wild varieties. By clearing brushwood, and by thinning and dressing, palm trees yield a double crop in the first year and a four-fold crop in 3 to 4 years. By the application of fertilisers, and the careful use of insecticides and fungicides, and by general careful cultivation, a great deal may be achieved.

Seed selection is an important question, and although trees do not always breed true to type, a great deal has been accomplished here. It may yet be possible to breed a high-yielding palm, producing a heavily oil-laden pulp with a large weight of kernels, thinly covered with protecting shell. At present, all the virtues cannot be found in a single species, any more than the cotton plant can be trained to give both a high yield of seed and of good fibre.

Experimental results may be selected at random from Malaya and Sumatra, showing greatly increased yields of palm fruit. Thus, twelve bunches, and an average weight of about 200 lbs. of fruit, were obtained per tree, a much greater average than that for West Africa. Some bunches weighed 100, 120 and 130 lbs. each, and it is believed that finality has not been reached.

The cultivation of oilseeds and oilseed bearing trees is relatively easy—although many factors, such as labour, transport and climate, enter into cost considerations—and a great increase in production and yield can be foreshadowed. Thus the palm will grow throughout a wide belt, north and south of the equator, at elevations up to 3000 feet (in some instances), with a mean annual temperature varying between 22° and 30° C., and will adapt itself to a rainfall varying between 40 and 250 inches per annum.

The point cannot be laboured, but it is evident that plant culture in all its ramifications will enable oil yields to be increased and price reductions to be made. The potential death-struggle of the natural oils and fats in a possible economic fight with artificially produced rivals is reminiscent of Samson, and it demands that the scientific pillars upon which a synthetic process is founded shall be stronger than the stone pillars of Gaza.

THE ROYAL WEDDING

The North British Rubber Co., Ltd., inform us that one of the boys in their employment will have the honour of being present at the wedding of the Duke of York as the representative of the boy workers of the industry. As the company is the largest rubber manufacturer in the British Empire this is a suitable choice.

THE GROWTH OF PLANTS

By L. A. JORDAN, D.Sc.

Many must have read with very great interest in your issue of March 16 Prof. Baly's reply to your previous contributor, Mr. White, who, in speaking of the growth of plants, asked a very innocent-looking question, "Does the plant make the chemical or the chemical make the plant"?

For my own part, as the question was asked in so gentle and disarming a manner, I hoped that Prof. Baly might have been induced to tell us how his work, following the fundamental syntheses now so well established, is likely to develop, and how far this road will take us towards the complete revelation of Nature's processes in living cells, whether of animal or plant origin. Science in these matters is fumbling with the mechanism, but will it be possible ever to reach the ultimate "vital force" itself?

Prof. Baly did approach the subject by saying that, in his view, photosynthesis is the real driving force behind all life and that the plant is the living mechanism developed from photosynthetic beginnings. I should like to hear Prof. Baly develop this idea, and if possible not confining himself to the plant world, for whilst animal and plant life appears in the bulk to be markedly dissimilar, there is a remarkable connexion between the operations of their respective living cells.

In view of the admitted value of sunlight for the maintenance of health, and the value of sunlight and X-rays in curative medicine, it would appear that photo-effects are important in animal cells, although not apparently in so fundamental a manner as in plant cells.

The plant cell acts as a conservator of energy; it absorbs carbon dioxide, water, a little nitrogen compound and the energy of sunlight which initiates the processes for making and storing up highly energised chemical products.

On the other hand, animals, which ultimately feed upon plant products, take these highly energised products and pass out lowly energised products as carbon dioxide and nitrogen compounds, the balance of energy being found as body heat or the power to do work. Neither plants nor animals produce new matter or new energy; they merely assimilate existing material and transform it into new forms.

Thus, considering the whole range of plant and animal life, the formation of formaldehyde from CO_2 and H_2O with its 130,000 calories per gram molecule, or at least the formation of the sugar by condensation from the formaldehyde, appears to be the peak of nature's energy curve.

The vital process in animal cells is clearly some sort of oxidation which produces substances with a gradual loss in energy content, and yet the materials oxidised, carbohydrate, protein and fat are about as insensitive to the oxygen of the air as carbon dioxide is disinclined to unite with water in ordinary circumstances to form formaldehyde.

Presumably in both cases there must be some agent to do this work; photo-synthesis, for the plant processes especially, and the conception of enzymes which may be described as a sort of organic catalyst. Enzymes, whilst themselves the product of a living cell—*i.e.*, vital force, can initiate the processes for which they are considered to be responsible, quite independently of the living cell which produced them. Enzymes are known as products of both animal and plant cells, but is the function of plant enzymes, as affecting the plant economy, as clear as in the case of the animal product, and are they sufficient to explain everything?

Another point of connexion between plant and animal cells is the wide range of mineral salts found therein which seem to be necessary for a normal life development.

Certain functions have been identified with the presence of mineral salts, such as the maintenance of the osmotic conditions proper for the cell; chlorophyll has been identified as a magnesium compound and the presence of iron in haemoglobin noted.

In plant life certain colour effects are associated with certain mineral salts, but can one be sure that the meaning of the presence of of these salts is fully understood? In animal life it is certain that mineral salts have a definite position in the normal body and that when they become dislodged disease follows.

Considering the widely different nature of the chemical processes undertaken, is it not astonishing that the agencies used should be so similar? Professor Baly and his collaborators have supplied a complete laboratory parallel to Nature's fundamental synthesis. It is a step by step development like this that will trace the sequence of the intermediate steps involved, and the manner of their development and connexion one with the other through the whole of Nature's cycle—from CO_2 to CO_2 again.

CHEMISTRY IN RELATION TO TINPLATE MANUFACTURE*

By H. J. BAILEY, O.B.E., F.I.C.

Inspector of Alkali etc. Works for Wales

It is the object of this paper to deal briefly with some of the chemical problems involved in this industry. The engineering side of the manufacture has been highly developed in the past, and no one can visit a modern tinplate plant without marvelling at the way the plates go through the various processes with a minimum of human handling, but the chemical part of the manufacture is largely carried on by methods handed down from the past, without any organised chemical research directed to elucidate the mechanism of the various processes. The object of the manufacture is to provide sheets of mild steel suitable for making up into drums or containers for all sorts of materials, and protected from corrosion by a surface coating of tin, which should be as thin as possible, in order to keep down the cost. In considering the chemistry of the manufacture it is always necessary to bear in mind this prime object, namely, a pliable plate of steel covered with a sheet of tin, uniform as far as possible in thickness, free from spots or blemishes, which will stand stamping or shaping without either the plate itself or the protective tin covering showing any signs of cracking.

---

* Read before the Swansea Technical College Metallurgical Society on December 16, 1922.

The industry in this country dates back to the 17th century, and the following data have been kindly furnished by the Welsh Plate and Sheet Manufacturers' Association :—The tinplate trade of South Wales ranks amongst the foremost industries in the country, because it is chiefly an export trade, about 90 per cent. of the output being exported. Board of Trade figures issued for the nine months ending September 30, 1922, show that while other trades of the country were still going through a period of stagnation, 334,452 tons of tinplates were exported during this period, amounting in value to £7,281,305. These figures also show how the tinplate trade is recovering from the slump of 1921, as for the nine months ending September 30, 1920 (a good year for the tinplate trade), exports of tinplates amounted to 265,925 tons. A greater amount of labour in South Wales is dependent upon the tinplate trade than might be generally supposed. The output of the steel trade of South Wales is largely consumed by the tinplate trade ; the bulk of the output of the South Wales acid works goes into the pickling tanks of the tinplate works, and the engineering works of South Wales are to a large extent engaged in manufacturing machinery for tinplate works or on repair, so that it is no exaggeration to state that about 50,000 operatives are directly or indirectly dependent upon the tinplate trade for their existence. The trade is singularly free from strikes and is very proud of its Joint Industrial Council, as, although now classified as coming under the Whitley Council Scheme, such a Council was in force in 1899, and was then called "The Tinplate Conciliation Board." Mr. Whitley publicly announced that his schemes was based entirely upon the principles underlying the old Tinplate Conciliation Board.

The present practice consists in rolling the steel bars to the required thickness in hot rolls, doubling, shearing, etc., until the required size of plate is arrived at. In this process the plates, which are finally rolled in thicknesses of eight sheets, often stick together, and have to be opened up by hand, and separated. The plates are then pickled to remove the surface scale, this "black pickling" being done in crates which move the plates up and down in a tank of hot weak sulphuric acid, three to five minutes being allowed for the completion of this process. The sheets of clean steel are then washed in water and piled up wet in the covered pots for the "black annealing" process, in which the pots are heated for 10 to 12 hours in an annealing furnace with a reducing flame. The annealed sheets are then rolled in cold rolls, usually through four sets, in order to give them a fine polished surface, the rolling being done across the plates as compared with the initial hot rolling of the steel. In this cold-rolling the sheets become hardened, which necessitates a further period of annealing commonly called "white annealing," an operation which is usually complete in about seven hours. These processes produce a further thin layer of scale, which is removed by a second pickling ("white pickling"), a process similar to the black pickling, except that the acid bath is not so strong and the time during which the plates remain in the acid is usually shorter. The white sheets then pass to the tinning pots, being kept wet to prevent rusting, until the tin-man is able to plunge them into the tinning bath. There are various styles of tin pots in use, but in each the chemical processes are essentially the same. The wet plate passes through a layer of strong zinc-chloride solution into the molten tin, and is guided by rolls until it emerges again from the tin-bath through a bath of palm oil. From the tinning pot the plates pass through the mechanical cleaning devices, any adhering palm oil being removed by bran or powdered earthy bodies, then to the sorting room, to be packed ready for market.

ANNEALING

The usual practice is to run the covered pots full of plates into long low brick chambers, fired by coal fires, fed with a long-flame coal, in order to have a reducing atmosphere. The firing and the time necessary to bring the whole mass of sheets up to the critical point (about 850° C.), are largely a matter of experience. The pots are then taken out and allowed to cool in the open shed. The base of the pot is of heavy cast iron provided with cast iron feet, and the covers, which are usually of wrought iron, fit over the plates on to the bed plate and are luted with sand. It is of interest to note that continuous annealing furnaces are coming into use, which do away with much of the labour of wheeling the pots in and out of the furnaces, the pots being placed by means of cranes on to cars, which become the moving base of the furnace. These continuous furnaces lend themselves to better control of temperature, and must reduce the fuel consumption considerably. Also, furnaces fired with producer gas and with properly regulated secondary air are on the market, and will, no doubt, in time commend themselves to manufacturers as more economical in fuel with greater ease of control. In the annealing of steel sheets it is only necessary to bring the whole of the sheets up to the proper heat and then to cool slowly. The cooling should be done in a reducing atmosphere, as much of the blue effect on the edge of annealed sheets is due to slight oxidation of the plates by the air drawn in through the sand lute on cooling. The object of annealing black plates wet is probably to check the tendency of the sheets to weld together, or, possibly, to prevent rusting when drying.

Pickling

The pickling of the plates, both the " black " and the " white " pickling, is now done with a weak solution of sulphuric acid reasonably free from arsenic. A fairly rapid action is desired as the cradles full of plates standing on edge are moved up and down in the solution for a few minutes only. Control of time and strength of acid are usually left to the " pickler," who likes to see a good seething from the plates, and has steam available to liven up his bath if the process appears sluggish. In some cases acid is run in from time to time to strengthen the bath, in others, the bath is used until the available acid is nearly all spent, the spent liquor being then run to the " copperas " plant or to the drain. Although generally the experience of the " pickler " is relied upon for correct conditions, in a few works tests have been instituted and the working conditions checked. For the black plate pickling strengths of acid equivalent to 5 to 8 per cent. of H_2SO_4 at the start are used, whilst for pickling the white plates from 2 to 4 per cent. of free acid is found satisfactory. The strength of the bath when exhausted varies greatly in different works, but in some cases is under 1 per cent. of free acid.

The addition of " sharps " to the acid bath is a long standing practice in many works, and after observing its use the author endeavoured to discover what exactly was its action. At first it was thought to be a purely physical action, namely, that of providing a great number of small points for the evolved hydrogen to escape from, and after an initial boil to leave the bath more or less quiescent until further solution of the iron gave rise to a fresh boil, but this explanation did not explain the continued quiescent action which persisted for some time after the sharps had been thrown in, or the equally satisfactory use of a clear solution made from sharps. Certain proprietary articles were found to be in use for the purpose of saving acid, and it was apparent that conditions could be set up in the pickling bath which reduced the evolution of hydrogen without apparently interfering with the removal of the scale. The problem seemed to be of such interest that an investigation of the reactions incidental to the pickling process was carried out in the laboratory of the Chief Inspector of Alkali Works, who has furnished me with some of the data. Results indicate that when a weak solution of sulphuric acid is used for pickling, say, 5 to 6 per cent. H_2SO_4, the scale is not *burst off*, as is so often supposed, by the evolved hydrogen produced by the action of the acid on the iron beneath, but is first reduced to FeO by the nascent hydrogen and subsequently *dissolved off* [equations I (*a*) (*b*) below]. Further, that in addition to these reactions, necessary for the proper cleansing of the plates, a secondary action occurs, whereby the clean iron is attacked by the acid, with evolution of hydrogen which can be measured. The reactions can be represented as follows :—

I (*a*) $Fe+H_2SO_4=FeSO_4+H_2$.
(*b*) $FeO, Fe_2O_3+H_2=3\ FeO+H_2O$.
(*c*) $3\ FeO+3\ H_2SO_4=3\ FeSO_4+3\ H_2O$
II $Fe+H_2SO_4=FeSO_4+H_2$.

In the presence of size, dextrin, etc., Reaction I proceeds quietly to a finish, leaving the surface of the metal smooth and bright, and Reaction II will occur to a very limited extent. Under ideal conditions Reaction I should occur alone ; and it is worthy of note that with size in use, no appreciable quantity of hydrogen is evolved for some minutes. For purposes of illustration the " scale " is regarded as FeO, Fe_2O_3 (Fe_3O_4), or magnetic oxide ; actually, however, scale is a compound or mixture of ferrous and ferric oxides in varying proportions, and the under layers are not magnetic, but approximate in composition to $6\ FeO, Fe_2O_3$. Direct estimation of the scale by reduction at red heat in hydrogen and determining the loss of weight is impossible, as the actual relation of oxygen to scale is unknown, but by calculation from such loss of weight, the percentage of scale can be determined for different assumed compositions.

The suitability of a given substance added to the pickling bath as " restrainer " would, from this point of view, be measured by its effect in reducing the action of the acid on the clean metal (Reaction II) to a minimum, whilst leaving Reactions I (*a*) (*b*) and (*c*) to proceed unchecked to completion. The " efficiency " of such a " restrainer " would, therefore, be in inverse ratio to the volume of hydrogen evolved measured under standard conditions of temperature and pressure. Check experiments were therefore made (*a*) by reducing the scale at a red heat in hydrogen and determining the loss in weight, (*b*) by determining the volume of hydrogen evolved, and the total loss in weight of the steel strips after pickling, and the weight of the ferrous iron in the pickle solution after the test. From these check experiments it was found that the attack of the acid on the clean iron was directly proportional to the hydrogen gas evolved within the limits of experimental error ; the whole of the scale being found in solution as ferrous sulphate save an insignificant amount of carbon. A standard test was then devised to determine the amount of such hydrogen evolved under controlled conditions of temperature, acidity, and amount of restrainer, and the results showed that, of the restrainers employed, size is one of the most efficient at all temperatures, and that it appears to work equally well with both sulphuric and hydrochloric acids.

The question of how "size," etc., acts as a "restrainer" in Reaction II without interfering with Reaction I had still to be determined. Size and similar materials reduce the surface tension of the liquor, and microscopic examination showed that when such materials are used the surface of the metal becomes coated with a fine layer of tiny bubbles of hydrogen, which act as a protective coating to the metal. The protective action of this layer of hydrogen is at a maximum where it covers clean metal, but is absent, or at a minimum, where scale or oxides of iron are present to react with the nascent hydrogen, and thus a protective layer comes into action automatically as the cleansing process proceeds. The possible advantages of the use of such a restrainer in the pickling process would be :—(*a*) Saving in acid used. (*b*) Less iron dissolved in the process. (*c*) Improved conditions at the pickling tanks, in reduction of acid mist rising with the hydrogen evolved. (*d*) A better surface on the plate, with the avoidance of pitting or sponging of the plate in pickling. (*e*) A reduction in the amount of tin required, by reason of the better surface.

On the basis of the former calculations it would appear that from 4 to 5 lbs. of commercial acid per box of tinplates should be sufficient to remove all the scale ; whereas a fair average figure for the trade appears to be from 8 to 9 lbs. per standard box, some works at periods use up to 14 lbs., and at a few works, the consumption is as low as 6 lb. per box. For every lb. of acid used above that which is necessary approximately ½ lb. of iron is dissolved according to Reaction II. One box of standard plates consists of 112 sheets, weighing from 106 to 108 lbs., the plates being 20×14 inches, or 436 square feet of tinned surface. The tin used is about 30 oz. per box, at about 1d. per oz. on present prices, roughly 0·07 oz. per square foot of tinned surface. At present prices steel represents roughly 0·8d. per lb., and from 130-140 lbs. of steel bars are required per box. The possibility of effecting a saving of, say, 4 lbs. of acid at ½d. per lb., 2 lbs. of iron and possibly 2 oz. of tin per box deserves attention.

Tinning

The process of tinning appears to be the formation of an iron-tin alloy on the surface of the sheet to which a layer of tin adheres, this layer being regulated in thickness by the temperature of the tin bath, and by the squeezing of the steel rolls through which the plates pass out through the palm oil surface bath. The use of zinc chloride as a flux preparatory to the entry of the plates into the molten tin has been developed in modern times ; formerly the plates were dipped into molten palm oil before being dipped into the tin bath. The exact action of the flux has not, so far as I am aware, been fully explained, but there is no doubt it acts as a dehydrating agent, and possibly as a cleanser, and there may be some action at the point of contact of the flux with the surface of the tin, though whether this action is chemical or merely one of surface tension is not known.

During the tinning process a certain amount of dross rises to the surface of the tinpot which, with the charred palm oil and scum on the surface of the flux, is commonly called scruff, and this is removed from time to time. This scruff contains a considerable amount of tin, which is recovered by heating in a small reverberatory furnace. One would like to see tinpots fired by producer gas, the temperature being regulated by a thermometer or pyrometer. There is usually a weekly clean-out of the tinpots when the pots are emptied, the rolls, etc., cleaned, and an accumulation of "hard metal" from the bottom of the pots removed. This hard metal is usually found to consist of iron and tin. By melting at a low temperature some tin can be recovered nearly pure. In recent years a tinning pot has come into use which combines the processes of white pickling, washing and tinning, in one mechanical operation ; as an engineering feat it is certainly a marvel of skill, and has reduced the labour required to a minimum. Whether it will be possible to extend the principles adopted in this machine is difficult to foretell, but if one could separate the plates after hot rolling, then cold roll, and anneal, it might be possible to pass the plates to a pot of the Melingriffith type, and with one pickling operation obtain a sufficiently good surface to tin right away. This will appear to be but a flight of the imagination, but given a suitable steel and proper temperature and chemical control at each stage of the operations, it may be a realisable dream in years to come.

In conclusion, reference may be made to a few of the problems on which research should be of great advantage to the manufacture.

(*a*) The most suitable temperatures and strengths of acid to be used in black and white pickling, and time of contact of the sheets with the acid, and the effect of the restrainers under controlled conditions.
(*b*) Cause of blisters, especially pepper blisters, streaks.
(*c*) Cause of hard or thick metal and recovery of tin from it.
(*d*) The problem of tin contained in the "list."
(*e*) The recovery of tin from waste plates.
(*f*) The action of the flux and the best strength to use on the tinning pot.

These would well repay investigation by the trade, and if this paper shows the value of research in one of the apparently simple parts of the process, namely, in pickling, and stimulates inquiry into the other chemical problems, the author will be well repaid. Thanks are due to Dr. Lewis Bailey, the Chief Inspector of Alkali, etc., Works, for assistance and to Mr. E. Linder for valuable data on pickling tests.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

DR. DUISBERG'S SPEECH

a few weeks ago, a report of which has just reached me, throws some light on the position of German Chemical Industry at the time he spoke. From it I gather that not only is Ludwigshaven closed down, but the Badische Anilin und Sodafabrik and the Oppau Works are in a similar plight, owing to shortage of fuel. Hoechst is only working partially, and the position in Elberfeld is also very difficult. The one bright spot would seem to be at the Leverkusen works, which are not only themselves within the British zone, but can obtain brown coal which is also within the British territory. The real point of great importance however, to the Dyestuffs Industry, is the amount of stocks which are held in Germany and elsewhere. These are said to be large, and may be sufficient to cover requirements for six months, and I see no reason to question this statement. No doubt what little production can be made will have to be put into stock owing to the shutting off of exports as the result of the French demand of a tax. At the moment there seems little chance of a settlement of the deadlock between France and Germany, and the trouble at Essen last week only makes things more difficult.

THE LEIPZIG FAIR

this year does not appear to have been a great success, and this must be attributed partly, I think, to the unsatisfactory manner in which contracts made at the 1922 Fair were carried out. No doubt the French occupation of the Ruhr had some effect, but the fluctuation of the exchange which fell to 200,000 in January, and rose to 100,000 in March, had much more effect in prejudicing the chances of success which the Fair may have had. German prices are now approximating to world prices, and unless there is a further slump in the mark, it appears unlikely that buyers will any longer rush to Leipzig in the hope of picking up bargains.

PROFESSOR H. E. ARMSTRONG

is, I hear, in Italy; but not, I hope, out of reach of the newspapers. He will be most interested in the Report of Sir Henry Norman's Committee on the use of lead paints. It should strengthen his somewhat slender faith in human nature of the governmental kind, or alternatively, should give him pleasure in having won a good fight against odds. This struggle is an interesting example of how we do things in our typically British fashion. It began in the International Labour Office in Geneva in 1921, when a draft convention was published which would have prohibited after 1927 the use of lead paints in the internal painting of buildings. I do not know whether Prof. Armstrong characterised this as "nonsense," but he might quite reasonably have done so. Now we arrive at the point where British commonsense comes into play. Lead paints are more economical than other paints; they are only dangerous when "dry rubbing down" is practised; therefore, prohibit "dry rubbing down" and not the use of lead paints. Simple, is it not?

DEFINITIONS

have a wonderful fascination for us Britishers. The subject receives as much attention in the Correspondence Columns as those headed "What is a . . . ?" Think how long we spent on "What is a fine chemical?" and now "What is a chemist?" has us in its grip. Judging from a letter in last week's issue, this is to be followed by "What is a doctor?" I saw in the *Glasgow Herald* a reply by Mr. J. Rutherford Hill to Mr. Chaston Chapman's letter on the question of the title "chemist." From it I gather that the main argument in favour of the retention of the title "chemist" is that "pharmacist" does not cover all the functions which the holder of that title is called upon to perform. In all these discussions I hope we shall not forget what is the main reason for the adoption of a particular appellation by any body of persons. It is certainly not to confer a dignity on any particular person in a class. It is only justifiable when it is in the interest of the public. If the restriction of a particular title to a certain ascertained number of persons enables the public to be protected from the unqualified practitioner in any calling, it is justified, and not else. I hope we shall not overlook this.

THE "CHEMICAL PUNCH"

is a title which I heard conferred on this paper by a distinguished scientist not long ago. I am not sure that this was intended to be entirely complimentary, but in some ways it is very apposite. It is evidence that the paper is now widely and quickly read. I sometimes hear its contents being discussed as early as Friday evenings. Advertisers have, no doubt, noted the growth in number of the letters in its correspondence columns, which is an excellent barometer. A week ago the editor showed me a letter, pointing out a slight error in the Market Report, which, I think, he was right in regarding as evidence of the minute scrutiny which readers give to the information the paper contains. My only grumble is that there is not enough healthy criticism from members of the Society.

FORTHCOMING EVENTS

Apr. 16. Society of Chemical Industry, *Yorkshire Section*, at the Queen's Hotel, Leeds. "Some Notes on the Production of Alkali by Bacteria as Registered by Different Indicators," by J. A. Reddie.

Apr. 16. Royal Society of Arts, John Street, Adelphi, W.C. 2, at 8 p.m. "Nitrates from Air," by E. Kilburn Scott, M.I.E.E. (Second Cantor Lecture.)

Apr. 18. The United Alkali Co., Ltd. Dinner in the Midland Adelphi Hotel, Liverpool, at 7.15 p.m., on the occasion of the One Hundredth Anniversary of the Establishment of the Alkali Industry in Great Brittain.

Apr. 18. The Royal Microscopical Society, 20, Hanover Square, W. 1, at 7.30 p.m. (1) "The Protozoa of the Soil," by D. W. Cutler, M.A. (2) "The Use of the Microscope in Palæobotanical Research," by Prof. A. C. Seward, M.A., F.R.S.

Apr. 19. The Chemical Society, Burlington House, Piccadilly, W. 1, at 8 p.m. Ordinary Scientific Meeting. (1) "The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. Part VII. Reactions of 2:5- and 4:5-Dinitro-m-xylene," by K. Ibbotson and J. Kenner. (2) "The Chemistry of the Three Carbon Systems. Part I. The Influence of the *Cyclo*hexane Ring on the $\alpha\beta$-$\beta\gamma$ Change," by S. F. Birch, G. A. R. Kon, and W. S. G. P. Norris. (3) "On the Promotion of Catalytic Reactions. Part I.," by S. Medsforth.

Apr. 20. Royal Society of Arts, at 4.30 p.m. "A Review of the Base Metal Industry, with Special Reference to the Resources of the British Empire," Sir R. A. S. Redmayne, K.C.B., M.Sc.

Apr. 20. The Society of Dyers and Colourists *Manchester Section*, at 36, George Street, Manchester, at 7 p.m. (1) "The Mechanism of Diazo-Coupling Reactions," by Dr. T. K. Walker, M.Sc. (2) "The Evolution of Bleaching," by S. H. Higgins, M.Sc.

Apr. 20. Society of Chemical Industry, *Newcastle Section*, and the Institute of Chemistry (Newcastle Section). First Joint Annual Dinner, to be held at the Royal Turk's Head Hotel, Grey Street, at 7.30 p.m.

Apr. 23. The Faraday Society. Meeting at Burlington House, Piccadilly, W. 1, at 8 p.m. (1) "On the Properties of Powders.—the Variation of Pressure with Depth in Columns of Powders," by J. H. Shaxby and J. C. Evans. (2) "The Properties of Powders." Part. VI. "The Compressibility of Powders." Part VII. "The Distribution of Densities in Columns of Compressed Powder," by E. E. Walker. (3) "On the Rate of Hydrogenation of Cinnamic and Phenylpropiolic Acids," by E. K. Rideal. (4) "The Temperature and Maximum Density of Aqueous Solutions," by A. Taffel. (5) "Note on the Coagulation of Milk by Acid," by L. Anderson.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1923

The Annual General Meeting will be held on Thursday, June 21, at 11 a.m., in the Arts School, Benet Street, Cambridge, and will be preceded by a meeting of the Council at 10 a.m. At the former, members will be welcomed to Cambridge by the Vice-Chancellor of the University, and the President of the Society, Dr. E. F. Armstrong, F.R.S., will deliver his address. The Vice-Chancellor will hold a reception to the Society at the Fitzwilliam Museum at 5 o'clock, and in the evening there will be a reception and dance in the Guildhall.

On the Monday, Tuesday and Wednesday of the same week, the International Union of Pure and Applied Chemistry meets in Cambridge, and the President of the Union extends a welcome to members of the Society to attend any of the public meetings of that body.

On Friday, June 22, the Society's Medal (1923) will be presented to Dr. C. C. Carpenter, who will then give an address. On the afternoon of the same day there will be an address by Dr. F. W. Aston, F.R.S., on "Isotopes," and in the evening the Annual Dinner of the Society, which ladies may attend, will be held.

On Saturday there will be a visit to Ely.

A programme of the meetings, with information regarding hotel accommodation, will be sent to members shortly.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

Volume VII of these Reports covering the year 1922 will be ready shortly and an order form with full particulars will be sent to every member of the Society as soon as the book is published.

NEWS FROM THE SECTIONS

BIRMINGHAM AND MIDLAND SECTION

The meeting on March 27 was held in the University of Birmingham, Dr. E. B. Maxted presiding, and three papers were read.

In the first paper, entitled "Some Studies in Catalytic Hydrogenation," the author, Mr. E. T. Lush, M.A., showed how the physical conditions of the addition of hydrogen to oils, by means of a nickel catalyst, lent themselves naturally to continuous working; the catalyst being a solid, the oil a liquid, and the substance producing the desired change, viz., hydrogen, a gas, it should be possible to distribute nickel throughout a closed vessel, keep the vessel full of hydrogen and allow oil to run in at one end and out at the other—the speed of flow regulating the degree of hydrogenation.

It was pointed out why porous supports, such as pumice, or asbestos, were unsuitable and why pure nickel was chosen. Various forms of nickel, such as wool and ribbons, were shown and some experimental evidence was briefly referred to showing that surface alone was not the factor of first importance, but rather surface activity.

After reviewing various methods of activation, anodic oxidation was described in detail. The activity of "activated" nickel surfaces, such as turnings, was shown by experiments to reside solely on the surface, but the possibility that the mass of nickel might act as a hydrogen reservoir received some experimental support. The course of hydrogenation, as measured by the analysis of samples taken at intervals, varied with the conditions of the operation. When the oil filled the vessel, completely covering the turnings, the proportions of the fatty acids present—more especially the ratio of oleic to iso-oleic acids—agreed with those published by Moore, except that the saturated acids increased regularly from the beginning. When, however, the oil flowed over the turnings as a film different results were obtained, the iso-oleic acid content being reduced. This difference was believed to be experimental evidence of the view of Moore that the formation of iso-oleic acid was the result of dehydrogenation of stearic acid since in the film method conditions were less favourable for dehydrogenation.

A small model plant holding 5 lbs. of oil was shown on the screen, and an example typical of a number of trials carried out in this plant was given :—Groundnut oil was run through continuously for 77 hours, leaving the plant at the rate of 5 lbs. per hour, with an average iodine value of 57—58, without any appreciable loss of activity on the part of the nickel, a sample of which as taken from the plant was shown. The author expressed his thanks to Technical Research Works, Ltd., in whose laboratories the investigation had been undertaken.

The Chairman observed that catalytic hydrogenation had fascinated many investigators, but the disintegration of the catalyst always seemed to crop up. If Mr. Lush were able to show, as he seemed to do, a catalyst, which, whilst possessing much activity did not disintegrate, he had taken an important step forward. It seemed very remarkable that nickel in any form should retain its activity for so long a time. He took it that the oil used was extremely pure and comparative figures in relation to the two forms of nickel (in the compact activated form and the finely-divided form) of what one might call the equivalent life would be of interest. If it could be shown that the equivalent life of nickel in the compact activated form was greater than nickel in the finely-divided form, an important economic step in oil hardening would have been taken. Dr. Hilditch congratulated Mr. Lush upon his work, which appeared to have broken fresh ground in the subject of oil hydrogenation. The recovery process seemed simple and effective. Mr. A. W. Knapp said he too was much impressed by the simplicity of the model plant; it was not only continuous but practically automatic. Mr. Thomas said the method, compared with existing methods, was alike simple and novel. It represented an advance in the ease with which the catalyst could be reactivated. With regard to nickel suboxide, in his experience this oxide or suboxide only acted as a catalyst in conditions under which it was, at least, partially reduced to metallic nickel. So-called oxide or suboxide catalysts increased in activity with repeated use, a fact obviously due to progressive reduction to metallic nickel.

A paper on "The Reaction between Ammonia and Sodium Hypobromite," by Messrs. D. R. Nanji, M.Sc., and W. F. Shaw, M.Sc., was read by the former. On adding ammonia to excess of an alkaline solution of sodium hypobromite at ordinary temperature it was decomposed. That this reaction was not the only one that occurred had not been recognised by certain investigators, for it had been suggested as the basis of volumetric methods for estimating ammonia. In the authors' experiments a modification of Willard and Cake's method was adopted, viz.: To determine the excess of sodium hypobromite the method employed was based on the well-known reaction between hypohalogenites and arsenious acid : $2\ NaOBr + As_2O_3 = As_2O_5 + 2\ NaBr$. To the solution containing the excess of sodium hypobromite was added excess of an approximately 2 per cent. solution of pure sodium bicarbonate and subsequently excess of a standard solution of sodium arsenite. The solution was then neutralised with dilute sulphurous acid, using methyl orange as indicator. It was then again rendered alkaline with 2 per cent. sodium bicarbonate solution and the excess of the arsenite titrated with standard iodine solution, using starch as indicator. The object of neutralisation was to remove any normal carbonate formed by the reaction of sodium bicarbonate with the free alkali in the hypobromite, before titrating with iodine. The accuracy of this method of determining hypobromite was beyond all doubt. They had found it possible to use much more dilute solutions of sodium hypobromite than those employed by Willard and Cake, and the authors' results showed that the reaction between ammonia and sodium hypobromite was not affected by employing solutions of that salt 20 times as dilute as those recommended by the authors mentioned. Taking into account the whole of their experiments, and the observations of other workers they submitted they were justified in advocating the rejection of the hypobromite method of estimating ammonia when the greatest possible accuracy was required.

Professor A. R. Ling said the contribution might not be of the highest importance because it was more on the negative than the positive side, but it was nevertheless necessary to put the investigations on record for the purpose of preventing research workers falling into error or doing needless work. Dr. Maxted said he regarded the information as most important from the latter point of view.

Mr. J. H. Bushill, B.Sc., read a paper describing work on "The Estimation of Acetone and of Ethyl Alcohol in a Mixture of the Two." The object of this work was to estimate these substances in comparatively small quantities in the products of bacterial fermentation. The disadvantages of the method of Northrop, Ashe and Senior (*J. Biol. Chem.*, vol. 39, 1) were pointed out, and preference was given to the method of estimating acetone devised by J. Rakshit (*Analyst*, 1916, p. 245), as by using lime water instead of caustic soda the method became quantitive as long as the ratio of alcohol to acetone did not exceed 10 : 1. The author preferred to estimate the specific gravity of the mixture, from which, together with the acetone content, the alcohol present could be calculated. For this calculation acetone gravity tables up to 1 per cent. had to be constructed.

The method was summarised as follows : a known volume of the liquid under investigation is made slightly alkaline with soda and distilled, the distillate being made up to a definite volume. The gravity of this solution is then taken and the acetone estimated by the method of J. Rakshit. By means of the acetone tables the gravity of the acetone present can be found and from this and the gravity of the mixture the gravity of the alcohol is estimated. The percentage of alcohol is then found from alcohol tables.

OTTAWA SECTION

At the meeting on January 11, a paper was read by Ross E. Gilmore under the title of "Some Notes on Denatured Alcohol in Canada."

Of the total of over 4 million proof gallons of ethyl alcohol produced in Canada in 1921 only about a third was classed as "Industrial, non-potable alcohol." Of this third roughly 60 per cent. was taxable and the remaining 40 per cent. was sold as denatured alcohol. There are 10 different grades of denatured alcohol authorised in Canada as compared with 3 in Great Britain and 81 in the United States. In Canada three grades are for unrestricted sale and represent roughly 30 per cent. of the total denatured alcohol sold. One of the remaining 7 restricted grades, namely, No. 1 Benzine, has a sale of over 50 per cent. of the total denatured alcohol produced, leaving only about 20 per cent. for the 6 other grades. The uses of the three unrestricted grades, viz., No. 2 Standard, No. 2 Benzol and No. 2 Pyridine, are mainly for burning, anti-freezing, paint and varnish. No. 1 Benzine, denatured with 9 per cent. wood alcohol and 1 per cent. benzine is used for the manufacture of varnish and shellac, drugs such as aspirin, phenacetin, etc. The uses of the remaining six grades are for special preparations, such as tincture of iodine, collodion, etc.

Methyl hydrate (wood alcohol) is the best denaturant, but its uses for special purposes are limited by the impurities required to be present in order to make it an effective denaturant. The lowest amount of methyl hydrate allowed as sole denaturant in Canada (*e.g.* No. 1 special for Hospitals and Universities, representing only 2 per cent. of total consumption) is 10 per cent. United States formula No. 1 specially denatured alcohol and also the Grade 1 industrial methylated spirits authorised in Great Britain contain only 5 per cent. of wood alcohol as sole denaturant. Other denaturants used in the Canadian Grades are benzine (kerosene), pyridine, benzol, nitrobenzol, pine oil, iodine, potassium iodide, ether, cadmium iodide, ammonium iodide, brucine sulphate and diethylphthalate.

Commercially pure industrial alcohol (not denatured), is allowed in the chemical industries at excise-duty rates ranging from \$0·15 to \$2·43 per proof gallon. Under the 15 cent rate comes alcohol used for collodion, tooth paste, ethyl chloride, chloroform, and soap. That for vinegar pays 27 cents duty per proof gallon, perfumed spirits 75 cents and proprietary medicines, pharmaceutical preparations, and extracts and essences \$2·40 to \$2·43.

There is as yet no specially denatured grade in Canada for motor fuel, but two grades containing benzol and gasoline respectively are authorised in the United States and one in Great Britain. After giving a short history of denatured alcohols in Canada and showing why the sale price in Canada of denatured alcohol was double that in United States and Great Britain, the speaker commented on the importance of the quality of the ethyl alcohol used to make the different grades.

MONTREAL SECTION

At the meeting held on March 19. at the Queen's Hotel, an address on "Recent Advances in the Rubber Industry," was given by Prof. G. S. Whitby, who also presented a paper in collaboration with Messrs. A. Cambron and A. R. Winn, on "The Acidity of Raw Rubber and the Influence of Bases on the Activity of Vulcanisation Accelerators." The meeting, which was presided over by Dr. A. R. M. MacLean, was preceded by a dinner, and was attended by 73 members, including Mr. S. W. Bridge, B.Sc., of London, who is in Montreal on a business visit. Prior to the delivery of the evening's address certain aspects of the Patents Bill now under consideration at Ottawa were discussed, and a Committee was appointed to draft a resolution, to be sent to the Government, emphasising the desirability of search prior to the granting of patents.

Prof. Whitby, in introducing his subject, said that the rubber industry had become an industry of the first magnitude only during the last decade or so. With this change of rank in magnitude there had been going on a change or rank in character, a change, not yet by any means completed, from an industry based on tradition and empiricism to one based on scientific technology and systematic investigation. The most substantial advances in the industry during recent years had been the use of organic accelerators of vulcanisation and improvement in compounding practice, particularly in regard to the use of new and more finely-divided substances. Good progress had been made in both the theory and practice of these subjects: the mechanism of the action of accelerators had been partially elucidated, and the cause of the effect of pigments had been formulated, at least in part, by Wiegand.

The term " accelerator " was used rather than the term " catalyst " to describe a substance which when added in small proportions to rubber mixtures hastened vulcanisation, because it was known that in many cases the substance introduced underwent change, and that not it, but a substance derived from it, by reaction with a metallic oxide, sulphur, or hydrogen sulphide, was the actual catalyst. Bedford had sketched out the types of reaction which accelerators might undergo, and according to him the most active accelerators functioned by the formation of polysulphides from metallic mercaptides. The accelerators generally employed industrially were comparatively mild ones, and were represented by hexamethylenetetramine, thiocarbanilide, aldehyde ammonia, diphenylguanidine, and anhydro-acetaldehyde-aniline. Extremely powerful accelerators were designated ultra-accelerators: a term which was defined by the speaker as indicating an accelerator of such potency that it would bring about vulcanisation under conditions of temperature and sulphur ratio such that vulcanisation would be substantially impossible in its absence. An example of an ultra-accelerator was piperidonium piperidyl dithiocarbamate; one part of which would in the presence of zinc oxide increase the speed of vulcanisation to 300-400 times its usual rate. An ultra-accelerator recently discovered by the speaker was zinc α-dithionaphtholate. Ultra-accelerators were already finding application in vulcanising rubber goods at room temperature. Under such curing conditions organic dyes could be satisfactorily used in rubber mixings.

A chemical examination of the resin of rubber made by the speaker and his co-workers had revealed the presence in the resin of a large proportion of acids, and the significance of this hitherto-unrecognised acid-content was pointed out. It was shown that if the acid was neutralised the activity of many accelerators was greatly enhanced. It was also pointed out that, as the acid-content of different samples of raw rubber varied considerably, this variation was probably an important factor in causing the variation in vulcanising behaviour displayed by different samples of crude rubber. A new and rapid method of examining the effect of organic substances on the rate of vulcanisation was described. One of the resin acids, hevëic acid, was found to retard vulcanisation, but its ammonium salt was found to be without such effect; the significance of this in regard to the behaviour of latex which has been preserved with ammonia was pointed out.

The speaker described recent developments, involving the direct use of latex; in particular, the process in which parallel threads were passed through latex in such a way that they were at the same time rubberised and converted into cord fabric. The method of building tyres, flat, on a drum, to which such fabric was adapted, was also described.

MANCHESTER SECTION

The annual meeting was held on April 6, Dr. E. Ardern, F.I.C., being in the chair. There were six nominations for membership on the committee, and as there were only five vacancies a ballot was held, Messrs. J. Allan, C. J. T. Cronshaw, G. D. Elsdon, S. H. Higgins, F. G. Jackson, and F. S. Sinnatt being elected. Messrs. Melling and Pettigrew acted as scrutineers of the ballot papers. Mr. H. C. Clanahan was appointed auditor. As there had been no nomination actually received for the appointment of the second auditor, the matter was left in the hands of the committee to deal with at a later date.

The hon. sec. of the section (Mr. L. Guy Radcliffe) read his annual report for the session 1922-1923. The report stated that the activities of the session commenced on October 6, when a large audience listened to an address by Dr. E. F. Armstrong, F.R.S., the president of the society. The second meeting, held on November 3, was held jointly with the Manchester Sections of the Institute of Chemistry and the Society of Dyers and Colourists, together with the Manchester Literary and Philosophical Society. The last-named society selected the lecturer, Dr. F. W. Aston, F.R.S., who gave an address on " Isotopes " to an audience numbering nearly 300. Soon after this lecture it was announced that Dr. Aston had been awarded a Nobel Prize and a Royal Society Medal for his researches. Prof. W. L. Bragg, representing the Literary and Philosophical Society, presided at this joint meeting. During the first two or three months of the session a special effort was made to increase the membership of the section, but, so far as could be ascertained, the results were not too satisfactory. At present the total number of members on the Manchester Register was about 550, and no less than 25 resignations from the society and of members on the Manchester List became effective on December 31, 1922. It was undoubtedly to the interest of every member of the society to do all he could to bring the advantages of the membership of the society to the notice of every eligible chemist. The Hospitality Fund had been well supported, but by comparatively few members, from whom the actual amounts contributed had been far in excess of the 2s. 6d., which every member was invited to subscribe.

The Chemical Engineering Group was invited to be present at the meeting held on December 1, when Mr. W. G. Fraser read a paper, entitled "The Chemical Engineering of Paper Manufacture," and there was a good attendance of members of the section, of the group, and of representatives of the Papermaking Societies. The fourth meeting, held on January 6, introduced an innovation in that the programme consisted of short papers by members, including one by Mr. E. F. Morris, which was read before the section under the arrangement made with the Chemical Society. There were three other papers, and it should be recorded that Dr. E. F. Ehrhardt's paper on "Patents for Chemical Products" (*cf. Chem. and Ind.*, March 29, p. 314) was regarded as being a very notable contribution to the subject. The arrangement by which several short papers with diverse subject matter were presented at the one meeting was generally approved by the members, and on February 2 the meeting again heard three papers read.

The sixth meeting, held on March 2, was a joint one with the Liverpool Section, and the proceedings commenced with a luncheon at the Queen's Hotel. The chairman and committee entertained a number of guests, including Sir Wm. Kay (chairman of the Corporation Gas Committee), the honorary officials and members of committee of the Liverpool Section, Dr. E. F. Armstrong (the president), E. V. Evans, Esq. (the hon. treasurer), Mr. W. J. U. Woolcock (of the Association of British Chemical Manufacturers), together with Dr. Longstaff and Dr. S. Miall. The Lord Mayor of Manchester (Councillor Cundiff, J.P.), and Dr. Clayton, M.P., the chairman of the Liverpool Section, wrote expressing regrets at being unable to be present. Altogether about 60 members and guests assembled at the luncheon, and brief speeches were made by Dr. E. Ardern, Sir Wm. Kay, Mr. John Allan, Dr. E. F. Armstrong, Mr. E. V. Evans and Dr. Holt. At the conclusion of the luncheon about 125 members of the Society availed themselves of the kind invitation of the Manchester Corporation Gas Committee to visit the Bradford Road Gasworks. In the evening, the usual meeting was held, at which about 130 members listened to an address from Dr. H. Levinstein (*cf. Chem. and Ind.*, Mar. 16 and 23, pp. 259-262, 294-297).

Dr. H. Levinstein has been elected chairman of the section for 1923-1925, and Dr. E. Ardern vice-chairman, whilst Mr. L. Guy Radcliffe has again undertaken the duties of hon. sec., these appointments being made by the committee in accordance with the rules of the section.

About 70 members attended the annual supper held on March 9, and the evening was very successful.

The ordinary general monthly meeting of the section was then held, about 75 members being present. Two papers were read by Dr. E. Ardern, the titles and authors being as follows: (1) "The Recovery of Nitrogen from Sewage by the Activated Sludge Process," by Edward Ardern, D.Sc., Clarence Jepson, M.Sc., and Percy Gaunt. (2) "The Activated Sludge Process, Withington Works," by Edward Ardern, D.Sc., and William T. Lockett, M.Sc.

In the first paper, the authors stated the result of investigations carried out some three years ago, both under laboratory and large-scale conditions, with the view of ascertaining what proportion of the total seawage nitrogen is recovered in the resultant sludge, when the sewage is treated by the activated-sludge process. The question of possible losses of nitrogen and the source of the high nitrogen content of activated sludge were also dealt with. It was claimed that under favourable operative conditions, as much as 30 per cent. of the total sewage nitrogen could be recovered in the sludge. No evidence was obtained of the fixation of atmospheric nitrogen or of the absorption and assimilation of ammoniacal salts. The results indicate that the high nitrogen content of the sludge must be ascribed chiefly to the flocculation of the sewage colloids which were richer in nitrogen than the gross suspended solids.

In the second paper a detailed account was given of a prolonged study of the operation of the activated-sludge plant at the Withington Works of the Manchester Corporation designed with the view of ascertaining the various factors influencing the complete and successful control of the process. As the result of information afforded by careful attention to the character of the sludge in circulation and the dissolved-oxygen content of the mixed liquor in the aeration chamber, it had been possible to increase the maximum effective capacity of this plant by some 25 per cent. The summary of analytical returns for the past 15 months showed that entirely satisfactory purification was maintained throughout this period, with the production of effluents readily complying with the standard recommended by the Royal Commission on Sewage Disposal, and the table of operating costs indicated that with the new air-compressing plant which was shortly to replace the existing compressor, such results would be obtained at a very reasonable cost, especially having regard to the relatively low capital expenditure involved in the adoption of the process. In conclusion, the authors stated that an additional unit of some five or six times the capacity of the existing activated-sludge plant was now under construction at these works.

MEETINGS OF OTHER SOCIETIES

THE BIOCHEMICAL SOCIETY

Three papers were read at the meeting held in the Lister Institute on March 12 :—

(1) "The Reversibility of the Action of Urease," by H. D. Kay. By continuous extraction, with butyl alcohol under reduced pressure, of a mixture of active urease and strong ammonium carbonate solution (containing carbamate) at room temperature, the author found urea to be present in the extract in small but definitely recognisable quantities. It was detected and estimated by a micro-urease method and by xanthhydrol precipitation. No urea was produced unless both active enzyme and ammonium carbonate were together present in the reaction mixture.

(2) "The Effect of an Air irradiated with the Mercury-vapour Quartz Lamp upon the Growth of Rats fed upon a Diet deficient in Vitamin A." by Miss E. M. Hume and Miss H. H. Smith. Rats receiving a diet deficient in vitamin A, and exposed for 10 minutes daily to the radiation of a mercury-vapour lamp, showed prolongation of growth for several weeks. Control animals on the same diet showed no such prolongation of growth.

(3) "The Possible Significance of Hexose-phosphoric Esters in Ossification," by R. Robison. Ossifying cartilage of young animals was found to contain an enzyme which rapidly hydrolysed hexose monophosphoric ester with formation of free phosphoric acid. Of the other tissues examined only the kidney contained the enzyme in comparable degree. In particular non-ossifying cartilage was almost inactive. The suggestion was made that this reaction may possibly play a part in the process of ossification. There is evidence that part of the phosphoric acid in the blood is present in the form of an acid-soluble ester and the hydrolysis of this would lead to an increase in the concentration of phosphate ions and the deposition of calcium phosphate.

(4) "The Storage in the Rat of the Growth-Promoting, Fat-Soluble, Organic Dietary Factor," by H. Goldblatt and Miss K. M. Soames. A very small amount (0·25 g.) of the liver of rats which had received cod-liver oil in their diet, and 0·5 g. of that of rats which had received butter, was found to be active when tested for the fat-soluble, growth-promoting factor by the biological method of Zilva and Miura. The liver of rats that had ceased growing after about 8 weeks on a diet very deficient in the fat-soluble organic factor was found to be inactive in doses of 0·5 g., and even 1·0 g. But 0·5 g. of the liver of rats that had been irradiated with the mercury-vapour quartz lamp for at least 4 weeks after they had ceased growing on a diet very deficient in fat-soluble A, was moderately active. This was perhaps further proof that the radiant energy of the mercury - vapour quartz lamp effected an economy of the growth-promoting fat-soluble factor in the body. Total darkness had no effect whatever on the growth of rats fed on a diet adequate in vitamin A content.

SOCIETY OF PUBLIC ANALYSTS

Mr. P. A. Ellis Richards presided over the meeting held in the Chemical Society's Rooms on April 4, when three papers were read.

(1) A paper on "Physiological Standards" was read by Dr. S. White, who observed that as many important drugs used in medicine did not lend themselves to chemical standardisation, it was necessary to adopt physiological standards. A number of individual drugs, including digitalis, ergot and *Cannabis indica* were dealt with, and a method described of arriving at the minimum lethal dose for frogs, and so establishing a heart tonic unit. The standardisation of Pituitrin was discussed, as were physiological methods for determining the presence of the three vitamins. The paper was illustrated by numerous slides.

(2) Dr. G. Monier-Williams described "The Estimation of Boric Acid in 'Liquid Eggs' and other Foodstuffs," and drew attention to the irregular results sometimes obtained with Thompson's method, owing to loss of boric acid by precipitation as calcium borate during the removal of phosphates. A method was described in which phosphoric acid was removed by precipitation as magnesium ammonium phosphate, the subsequent titration of the boric acid being carried out by Thompson's method.

(3) An account of "An Investigation into the Chemistry of the Reinsch Test for Arsenic and Antimony, and its extension to Bismuth" was presented by B. S. Evans, M.B.E., B.Sc. After giving a summary of the literature relating to the reaction, a method was detailed for determining the velocity of the reaction, and a number of curves given showing the influence on the reaction velocity of varying chloride, acid strength or arsenic (antimony, etc.), also the effect of adding cupric or cuprous salts. The products of the reaction are :—For arsenic—the compound Cu_5As_2; for bismuth—the element bismuth ; for antimony — the compound Cu_2Sb, followed by deposition of the element antimony. In all cases cuprous chloride went into solution. An attempt was made to elucidate the mechanism of the reaction, and experiments were outlined leading to the conclusion that it was due to reduction of the arsenic (or antimony, etc.) by a film of hydrogen on the surface of the copper. Under certain given conditions, the test used qualitatively could be made sensitive to less than 0·01 mgm. per 100 c.c. It was suggested that a determination of the reaction velocity carried out in any doubtful liquid would readily show whether any substance was present which would interfere with the test.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

At the meeting held on March 28, a paper was presented by Mr. Lenglen on "The Role and Importance of Lime in Agriculture." The lecturer, who is a director of the syndicate which is engaged on propaganda for the greater use of fertilisers, first discussed the part played by lime in the soil, and showed the effects it produces on plants and on livestock. The action of lime in rendering potassic and phosphoric fertilisers more available was discussed, and it was pointed out that lime accelerates the conversion of nitrogenous fertilisers into ammonia, and favours the action of nitrifying bacteria which always develop more abundantly in a slightly alkaline soil. After remarking on the destructive action of lime on certain soil parasites, Mr. Lenglen observed that the acidity of soil was of several kinds—direct acidity, such as that of marshes, and which is directly injurious; indirect acidity, due to humic acids which, in the presence of a base of a fertiliser, yield free acidity owing to the formation of an alkaline humate, liberating free mineral acid; and "exchange" acidity, produced when the soil is treated with a neutral salt such as a potassic or nitrogenous fertiliser, an acidity which forms through the exchange of the base of soil silicates with that of the compound introduced. If the silicates contain much iron or aluminium, salts are formed which are distinctly acid and toxic to plants. The decalcification of the soil must therefore be avoided by adding lime, calcium carbonate, or marl, etc. In conclusion, the lecturer remarked that if these theories were applied, it would be possible to say "à pere pauvre succéderont des fils riches."

Monsieur Chaudron communicated the results of his researches on the preparation of devices for obtaining high temperatures in the laboratory, and described a furnace which he had designed to attain 2000° C. and which worked in a vacuum. The furnace consisted of three essential parts, lying on each other and held together merely by their own weight. The lower part was utilised to provide the electrical connexions, the central part was the working area, and the upper part the cover. A perfect vacuum could be obtained in this apparatus. which was provided with a heating element composed of an alundum cylinder containing titanium wires; the crucible was placed inside this cylinder. The furnace was easy to manipulate.

INSULIN

The technical difficulties of manufacturing insulin have already been overcome by The British Drug Houses, Ltd., who, working in conjunction with Messrs. Allen and Hanburys, Ltd., have now put the product on the market. Insulin is the new specific for diabetes, which was discovered by two Canadian physiologists, Messrs. Banting and Best.

CORRESPONDENCE

THE TITLE "CHEMIST"

Sir,—It would appear desirable to support the plea recently so admirably stated by Mr. Chaston Chapman, the President of the Institute of Chemistry, in your columns for the restriction of the word "chemist" to those who practise chemistry in the full sense of the word. Surely the time has arrived when we can come to an amicable agreement with our friends, the pharmacists, on this point, and I venture to suggest that much would be gained if it were possible to hold a round-table conference officially representative on the one side of the Pharmaceutical Society, the retail Pharmacists' Union and any other bodies concerned, and on the other side, of the leading chemical Societies.

The object of such a conference would be to discuss the possibility of agreeing as a point of professional etiquette to the limitation of the terms "pharmacist" and "chemist" in the sense defined by Mr. Chapman.

If this could be achieved the rest would follow and with the support of the Press the public would soon learn the proper meaning of the terms.—I am, Sir, etc.,

E. Frankland Armstrong, F.R.S.,
President of the Society of Chemical Industry

BAYBERRY OIL

Sir,—In answer to the inquiry, "Bayberry Oil," in the issue of *Chemistry and Industry* for March 9, p. 241, the following work was done in this laboratory on material known as Bayberry Tallow that was extracted from a berry growing on a small bush found along the Atlantic Sea Coast at New Jersey, U.S.A. The fat was obtained by placing the berries in boiling water, and skimming off the fat that came to the top. The material extracted was a greenish yellow fat of very hard consistency with a very pleasant aromatic odour, and had the following constants:—

Saponification value, 207·3.
Free fatty acids, 2·10 per cent.
Unsaponifiable matter, 0·39 per cent.
Iodine number, 3·7.
Acid value of the fatty acids, 217·0. Titre 56·7.

AL-RĀZĪ AS A CHEMIST

Sir.—The interesting article on Al-Rāzī in your issue of February 16 contains one or two points which call for comment. (1) A manuscript of the *Kitab sirr al-Asrar* (not "assar"), *i.e.*, the Book of the Secret of Secrets, was described by Naumann in 1838 in his catalogue of the MSS. in the City Library at Leipzig. This differs in some respects from that at Göttingen, and also from a third which was investigated by Prof. Stapleton. (2) A Latin translation of the work is preserved in the Bibliothèque Nationale (MS. 6514)—a fact which is of importance inasmuch as up to the present very few Arabic originals of mediæval Latin alchemical books which profess to be translations from Arabic have hitherto been unearthed. (3) Surely it is incorrect to say that the Greeks of Al-Rāzī's time were not acquainted with sal-ammoniac ? The earliest Muhammedan chemists, Khabid and Jabir, knew sal-ammoniac well, and their chemistry was directly derived from the Greek school at Alexandria. The earlier Greeks certainly employed sal-ammoniac in preparing various forms of *thion hudor*. (4) I find no justification for the statement that "most of the names of . . . apparatus found in his (Al Rāzī's) books are of Persian origin." *Tabistan* is admittedly Persian, but most of the other names are Arabic. As for the names of "rocks, earths and artificial products," while many are Persian a great many are directly derived from the Greek. (5) "Zarruch" is presumably a misprint for *zarnīkh*.—I am, Sir, etc.,

PERSONALIA

The Secretary for Mines has appointed Sir Frederick L. Nathan, K.B.E., Mr. J. D. Morgan, M.Sc., M.I.E.E., A.M.I.C.E., Mr. W. Rintoul, O.B.E., F.I.C., and Prof. R. V. Wheeler, D.Sc., to be a sub-committee of the Explosives in Mines Research Committee to investigate the means employed for firing explosives.

Mr. F. Fairbrother, M.Sc., has been appointed lecturer in chemistry in Manchester University.

Dr. W. Rosenhain, chief of the Metallurgical Department of the National Physical Laboratory, is at present lecturing in America on metallurgical subjects, and Sir J. J. Thompson, Professor of Physics in Cambridge University, is now lecturing at the Franklin Institute, Philadelphia, U.S.A.

* * *

The death is announced of Sir John Watney, for many years clerk of the Mercers' Co., and long associated with the City and Guilds Institute for Technical Education.

With regret we record the death of Prof. E. W. Morley, well known for his association with Prof. A. A. Michaelson in their experiments on the velocity of light. Prof. Morley also published classical papers on the atomic weights and densities of oxygen, hydrogen, etc.

From Germany the death is announced of Dr. A. Scholl, a well-known worker in the field of food chemistry.

NEWS AND NOTES

BRITISH INDIA

Second Forecast of the Winter Oilseeds Crop

Estimates based on reports received from provinces containing 98·7 per cent. of the total area under rape and mustard and 99·2 per cent. of the total area under linseed in British India indicate that the acreage (excluding the mixed crops of the United Provinces) under rape and mustard totals 3,693,000 and under linseed 2,499,000. These figures represent increases of 6 and 21 per cent., respectively, above the areas estimated at the same time last year. The present condition of the crops is reported to be good, except in Bengal, where the plants were adversely affected through continued absence of rain.—(*Ind. Tr. J., Mar.* 15, 1923.)

CANADA

Mineral Production in 1922

The value of the Canadian mineral output in 1922 was $183,000,000, an increase of $11,106,000 over the value recorded in the previous year. The value of the metal output was $61,000,000, of non-metals $82,500,000, and of structural material and clay products $39,300,000. An outstanding feature of the metal production was the increased output of gold in Ontario and British Columbia, the total Canadian production for the year increasing by 31 per cent. to 1,230,985 ozs. Silver advanced 30 per cent. in quantity, and 40 per cent. in value, whilst lead showed an increase of 41·2 per cent. in production and over 77·3 per cent. in value. Nickel and copper declined compared with 1921, but the advanced price of copper checked the decline in value to 2·6 per cent., the decrease in quantity being 9 per cent. The increase in the output of zinc by 6 per cent. was emphasised by higher prices. Cobalt production revived, 443,000 lbs. being produced, an increase of 76 per cent. in quantity and 91 per cent. in value. Coal production totalled 15,000,000 tons, valued at $66,486,025. The output of natural gas was 14,954,097 thousand cubic feet, valued at $5,468,963. A total of 136,657 tons of asbestos ($4,664,106) was produced, thus showing a large increase. The decline of $5,260,343 in the output of non-metallic minerals was due to labour troubles. On the whole, the state of the mineral industry may be considered as satisfactory, the total values attained having been exceeded only in 1920, 1919 and 1917.

UNITED STATES

The Organic Chemical Industry

The second annual meeting of the Synthetic Organic Chemical Manufacturers' Association was held in New York on March 8. Dr. C. H. Herty, President of the Association, reviewed events during the past year, and said that it had been a most remarkable period, as the industry had had to struggle for protective legislation, and at the same time protect itself against attacks upon the holding of patents authorised by the Government. In the course of the year the industry enjoyed, however, much more public understanding, relations between producers and consumers were more cordial, and sufficient orders were being placed to suggest that more prosperous times were ahead. Mr. F. P. Garvan, President of the Chemical Foundation, spoke of the endowment of research that had resulted from the campaign conducted by the Foundation in order to educate the public as to the value of chemistry, and pointed out that chemical manufacturers should also do their share in providing for the utilisation of the results of these efforts on a commercial scale. The necessity for co-operation between American manufacturers in order to produce a wider range of products, particularly dyes, was emphasised by pointing to the policy of the Interessengemeinschaft of accumulating profits in America from the sale of materials imported to compete against American industry.

FRANCE

A "Laboratory Day"

A "Laboratory Day" will be held in France on May 27, on the occasion of the centenary of the birth of Pasteur, and contributions then received will be utilised to equip research laboratories with apparatus, and to encourage research work.

A New Liquid Fuel Institute

The Minister of Public Instruction and of Fine Arts has issued a decree dated March 27, approving the decision of the Council of the University of Montpellier to establish an Institute for Liquid Fuels in the faculty of science at that university. It is interesting to note that a Petroleum Institute in the science faculty of the University of Strasbourg has already been working for nearly two years under the direction of well-known scientists and industrial leaders, and that extremely useful results have been obtained.

GENERAL

A New Alloy for Firebars

The burning of cast-iron firebars is one of the difficulties with which the engineer has to contend, as a set of bars can quite possibly be melted in a few weeks, and the troubles thus caused in connexion with mechanical stoking have been one of the serious disadvantages of this method of firing during the past century. Much light on the subject, however, has recently been thrown by researches of the International Combustion Corporation, Ltd., of Derby, as a result of which a new alloy, known as "Usco," a special variety of cast-iron, has been devised to overcome most of the difficulties. The action of the furnace consists of two distinct operations: (1) the melting of the iron, and (2) oxidation, but about 90 per cent. of the trouble is due to oxidation. Ordinary foundry iron contains, as chief impurities, phosphorus and sulphur, which, at the high temperature of the furnace, form phosphides and sulphides of iron. These melt at about 1740° F., so that as soon as a cast-iron firebar reaches this temperature it becomes porous, and the phosphides and sulphides melt and run out, leaving an expanded mass of pure cast-iron. This porous mass oxidises rapidly at about 1830° F., *i.e.*, at a lower temperature than ordinary non-porous cast-iron, the outer layers of the bar being converted, in turn, into purer cast-iron, steel, pure cast-iron and, finally, iron oxide. Graphitic carbon and silicon also add to the trouble, but the main cause is the phosphorus and sulphur. The new alloy is stated to have overcome all these troubles, as it consists of a special form of purified cast-iron with a much higher melting point and tensile strength. Its life is claimed to be from 3 to 10 times that of ordinary cast-iron, and it pours without difficulty and does not crack. The cost is only about 50 per cent. more than that of ordinary cast iron, and the qualities of the new alloy can thus easily be tested at little expense.

Italo-American Agreement for the Sale of Sulphur

Negotiations have been proceeding between the American and Italian producers of sulphur for some time past to obviate competition and to improve the position of the industry. It is now announced that a selling agreement has been reached, and it appears that, although no particulars have been issued, prices have been fixed for a period of 18 months or until the end of September, 1926. The agreement will be renewed automatically for a further period, unless cancellation is requested six months previously. It is understood that American producers will be restricted to the North American market and the Sicilian industry to Italy, other markets being allocated on the basis of the respective outputs of the two industries. The fixed allocation for export from Italy is 145,000 tons per annum, but the Italian producers can sell to any country an amount not exceeding 65,000 tons per annum of raw sulphur for the manufacture of sulphuric acid, making a total agreed export of 210,000 tons per annum. Details of the price arrangements will be awaited with interest, as American prices have been much smaller than the Italian ones. Further, the Italian production in 1922 was only 137,640 t. compared with 240,089 t. in 1921; exports from Italy in 1922 were 133,264 t. compared with 147,640 t. in 1921 or more than 200,000 tons below the pre-war average; and it is stated that large stocks still exist in Sicily. The head offices of the combine will probably be established in London under the management of representatives of both interests.

REPORT

Report of the Departmental Committee Appointed by H.M. Home Office to Re-examine the Comparative Efficiency, Cost and Effects on the Health of Workers of Lead and Leadless Paints. *Pp.* 66. *H.M. Stationery Office,* 1923. *Price 2s. 6d.*

(Specially Contributed)

This Committee, consisting of the Rt. Hon. Sir Henry Norman, Bart., M.P. (Chairman), Messrs. C. Bellhouse, C.B.E., O. J. Kauffmann, M.D., T. M. Legge, C.B.E., M.D., A. Munby, F.R.I.B.A., A. Scott, F.R.S., D.Sc., and H. O. Weller, M.I.C.E., A.R.I.B.A., has just issued an interesting document.

The introduction refers, at some length, to the reports (in one case a majority report) of the earlier House-Painting Committee and Coach-Painting Committee, and gives reasons why the findings of these committees have not been accepted by the new Departmental Committee, the main reason being the experience of substitutes for white lead used during the last ten years. After reviewing the determinations by Mr. C. A. Klein of the amount of dust, and of the lead contained in it, in the air breathed by painters engaged in the dry-rubbing down of old paint and in the wet-rubbing down, the Committee recommends "that dry-rubbing down be prohibited."

The allegation that poisoning by turpentine and turpentine substitutes is responsible for much of the so-called lead poisoning amongst painters is dealt with in detail, and is not substantiated to the satisfaction of the Committee whose report on this point is as follows: "We conclude that there is not sufficient ground to warrant us in accepting the view that turpentine poisoning is the cause of the leading symptoms commonly attributed to either acute or chronic lead poisoning, nor in attributing to the inhalation of the fumes of turpentine and other thinners the occurrence of chronic Bright's disease." But the Report recognises the injurious effect of some of these fumes and recommends ventilation of confined spaces during painting.

The evidence of the Director of Works in H.M. Office of Works was carefully considered. His Department had since about the year 1913 made considerable use of zinc base paints, and one gathers—though it is not definitely stated—that this practice was the result of some external pressure, for all the officials responsible for the large maintenance services of the Department spoke of the serious depreciation and lack of durability of the zinc paints in use. It was "practically a universal opinion on the part of fifty or sixty such officers that zinc base paints did not stand externally at all well." Analyses of paint scrapings, taken from exposed surfaces last painted with zinc base paints were made by the Government chemist showing the zinc content in the scrapings to be very small. In many cases it seemed the new zinc paint had almost entirely disappeared, and the scrapings mainly consisted of white lead paint applied many years ago. It is interesting to note that the Director of Works felt unable to make the proper economies in his estimates, unless allowed to return to the use of white lead, and appealed to have such government buildings as post offices and county courts excluded from the principle of prohibition of lead paints for internal painting if the Geneva Convention was applied to this country.

The conclusions reached by the Committee on the question of the painting of buildings are definite. "We are satisfied that for outside painting, and for certain kinds of internal painting, there is at present no efficient substitute for lead paint." The Geneva Convention is recommended for legislative sanction with some modifications, and regulations to deal with the continued use of lead paint are recommended for adoption at an early date. The Committee states: "We have to point out, however, that the evidence placed before us shows that, at present, any prohibition of the use of lead paints for certain purposes is likely to involve an increase of cost. This conclusion is based on the consideration of the total outlay required to maintain, respectively, lead and existing leadless paints in comparable condition over a reasonable period of years."

Other recommendations deal with coach painting, notification of lead poisoning among house painters, and the need for further research in paint technology.

At the urgent request of the Office of Works the Committee considered the policy of using leadless paints on Government buildings: "The cumulative effect of all the new evidence was obviously that there was a marked increase of cost involved in the maintenance of external surfaces painted with non-lead paint. . . . We are satisfied, however, that the dangers attendant upon the use of lead paint can be minimised by means of Regulations providing for the abolition of dry rubbing down, for adequate arrangements for personal cleanliness, and where necessary for medical examination of the workers." The Report also refers to the degree of solubility of lead sulphate, and the poisonous character of this and some other pigments, but without going into these matters in great detail. Analyses of paint scrapings, statistics, particulars of the state of various government buildings, draft regulations and certain documents are found in the Appendix.

* * * * *

It is not often that one Departmental Committee comes in so definite a manner and after so short an interval to conclusions which are so subversive of the labours of previous Committees. The perusal of this report, and some other reports on this rather difficult topic, leaves on one's mind the impression that some of the earlier Committees were chosen not to investigate the policy which was most desirable in the interests of the community, but how a particular policy, which seemed to someone in authority a proper one, could most conveniently be put into operation. Complaints were freely made as to the methods of some of the earlier Committees, and if the above surmise is well-founded the divergence of view between the old Committees and the latest is not surprising. Sir Henry Norman's Committee included, besides an experienced Chairman, two Home Office officials, two men with medical knowledge, two architects, and two with chemical knowledge adequate for the subject to be investigated. The details of evidence given in the report, though scanty, appear to justify the main conclusions arrived at, and the verbatim evidence will be read by many with a good deal of interest. There is no obvious background of bias or prejudice in the report; the members of the Committee, indeed, appear to have considered the evidence with impartiality and a desire to get at the facts. It will be a surprise if some of the witnesses complain as a certain eminent Austrian complained when he was invited to give evidence before an earlier Committee. It is hardly to be expected that this report will be as fiercely attacked as was a "questionnaire" mentioned in it. Yet this report will not be entirely satisfactory to any of the parties most intimately affected; the lead industry and the zinc industry will each feel they could have better brought out some pertinent fact, the employers and the workers will each anticipate some troublesome times to come, but perhaps the severest critics of all will be the officials of the International Labour Office at Geneva, whose strongly partisan attitude on this question finds no reflection in this almost judicial report. Lord Askwith's recent letter to the *Times* suggests that already some of the chiefs at Geneva are preparing an onslaught, nursing their wrath to keep it warm, and it may be they will again disinter the lead emanation and furnish the unwary with cinema shows of dubious origin and suitable extracts from the writings of Monsieur Souris. Whether the Department of Scientific and Industrial Research would be wise in undertaking a thorough investigation of painting conditions is a matter of opinion. Proper paint tests would take many years and involve the expenditure of many thousands of pounds. It is no slight task to paint under carefully measured conditions, surfaces of wood, iron and other substances, with half-a-dozen pigments, both in external and internal situations, in the pure air of the country, the salt air of the coast and the acid air of the towns, in dry and in very wet climates, and to inspect these at suitable intervals with necessary repaintings, and then to know what each has cost in labour and materials. Some persons think that the money could be better employed in other ways.

THE NORMAN COMMITTEE REPORT

By PROF. H. E. ARMSTRONG, F.R.S.

Although a proper course would be to await publication of the evidence upon which it is founded before discussing the Report of the Home Office Departmental Committee on Lead Paints, yet in view of the obligation our Government is under to ratify *or otherwise* treat the Draft of Convention "adopted" at Geneva in November, 1921, on or before the 19th of May proximo, a few remarks may be permitted.

To one who, like myself, has had the nightmare of white lead upon him during a dozen years past, it is satisfactory to be at last able to deal with a rational document. Those of us who have fought consistently and persistently against the false statements and views prevailing from 1911 onwards may at last claim to have been justified in their resentment of the treatment lead has received at Government hands. The present Report clearly nullifies the findings of the two previous Committees.

Misrepresentation is not yet stayed, however. At a meeting recently held in Paris (March 3), referred to in the *Times* last week by Lord Askwith and Sir Claude Hill, the latter a Red Cross Knight, apparently with small qualification to deal with the subject of lead in any shape or form (unless, perhaps, it be dum-dum bullets), the old attempt was made, following the tactics adopted by Monsieur Thomas and his myrmidon at the Geneva Labour Office, to prejudice the issue by sensational, misleading and unwarrantable statements. The lecturer, Monsieur H. L. Breton, quoted experiments which he asserted gave proof of the issue from lead paint of poisonous plumbiferous vapours. I would give the lie direct to such ancient vintage of false observation. Mr. C. A. Klein, and I, over and over again have examined the statements made by various observers here and abroad, that lead is volatilised during the drying of paint. We have proved that they have been in error in every case. The Government Chemist has corroborated us. When, in giving evidence to the Norman Committee, I began to refer to this matter, I was at once stopped by Dr. Legge with the remark, "that question is quite closed."

The Norman Committee, in fact, has reduced the issue to very simple dimensions—to a question of dust. It is now admitted that the one real danger is that arising from the dust produced when paint is rubbed down dry—further, that the production of such dust may be obviated by wetting the surface and then rubbing down with a wetted waterproof sandpaper.

To make painting an ideally healthy occupation, indeed, one to be sought after and preferred, it is only necessary to provide that painters always wet—I will not say with what or what. Otherwise, No Prohibition!

The Committee, however, have not had the courage of their convictions, the courage to be logical and say to Government: Let Monsieur Thomas and Co., and all the maladroit machinery of Geneva, go hang. There is no longer need to fear lead paint. Don't hamper industry, rather seek to promote it. They have treated the Convention seriously, whereas it was a farce (see my article in Nos. 2 and 3 of *Chemistry and Industry*). Dr. Legge, being a member of the Committee, could not well do otherwise, I imagine, than advocate the acceptance of the Convention which was of his promotion; had he not intervened at Geneva, there would have been no Convention voted of any kind. In fact, Sir Montagu Barlow, just before the vote was taken, made the cryptic statement: "The position of Great Britain has been plain all through. Great Britain has declined to take part in the matter so far as it is contentious." It never was otherwise. Not having voted at the early stages when their votes would have changed the issue, the British delegates should have abstained to the end. The decision taken was pure Quixotism.

Is, then, a most serious blow to be delivered at the lead industry in Australia and elsewhere? Are British householders generally to be denied the use in their homes of the most effective paint known, merely because a wave of madness passed over an inconsiderate polygot sentimental assembly in Geneva? If industries are to be subject to such influence and interference, the sooner the influence be removed the better. That we should contribute £40,000 a year to maintain in luxury an institution in Geneva engaged in the brewing of such wickedness is Gilbertian, the more as we are starving our home institutions.

PARLIAMENTARY NEWS

Trade in Carbon Black

Answering Mr. R. Young, Lt.-Col. Buckley said that the quantity and value of imports of carbon black during 1920, 1921, and 1922 were 59,020 cwts. (£284,507), 49,320 cwts. (£200,350), and 77,606 cwts. (£278,384), respectively. In 1922 the imports originated as follows:—Netherlands 948 cwts., Germany 6646 cwts., United States 68,467 cwts. and other countries 1545 cwts. Re-exports during the three years in question were 1146 cwts. (£7181), 775 cwts. (£4792), and 1201 cwts. (£5081). In 1922 Denmark took 213, Netherlands 76, France 538, and other countries 375 cwts.—(Mar. 28.)

Dangerous Drugs (Imports)

Mr. Bridgeman, in a written answer to Mr. Gilbert, gave the imports of opium as 423,530 lb. in 1920, and 58,161 lb. in 1921. Imports of morphine and morphine salts during the two years amounted to 320 and 1100 oz. respectively and of cocaine and cocaine salts to 7227 and 24,663 oz. respectively.—(Mar. 28.)

Imports of Dyestuffs from the United States

Replying to Mr. G. White, Lieut.-Col. Buckley gave the following figures of imports of intermediates and coal-tar dyes from the United States during the three past years, the value being shown in parentheses: *Coal-tar intermediates*, including aniline oil and salt and phenylglycine:—1920, 2226·3 long tons (£736,221); 1921, 66·2 t. (£27,891); 1922, 1 cwt. (£8). *Finished coal-tar dyes*:—1920, 781·8 t. (£532,897); 1921, 60·9 t. (£35,576); 1922, 7·5 t. (£1444).—(Mar. 26.)

Safeguarding of Industries Act

Sir P. Lloyd-Greame informed Mr. Rose that the available facts did not support the suggestion that the Act tended to encourage importation of Belgian and other glassware at the expense of German, and failed to protect the British manufacturer. He was not prepared to cancel the Glassware Order under Part II of the Act.—(Mar. 27.)

Adjournment of the House

The House adjourned from March 29 till April 9.

COMPANY NEWS

THE BRITISH ALUMINIUM CO., LTD.

The annual meeting was held on March 27. Mr. A. W. Tait, who presided, said that the net profit for the year was £229,235 as against £221,506 in the previous year, and the trading profit £195,231 compared with £183,041. As the demand was small at the beginning of the year the aluminium works in Norway and the alumina works in this country were closed, but were re-opened later on in the year. The output at the works in Scotland and Vigelands, Norway, was greatly increased, reaching full capacity in the autumn. A small aluminium works at Stangfiord, Norway, was brought into operation this year. Trading conditions during the past year were abnormal and, owing to competition, prices were low. At present the company could not compete in Continental markets owing to the exchange and to other restrictions. Since the beginning of 1923, demand had improved and all the company's works were producing at capacity, but prices had not materially improved. Owing to the improved situation, an interest had been secured in a company owning two factories in Norway, which had been shut down for some time, and one of these works would come into operation very shortly. The company was not proceeding with the Lochaber water-power scheme owing to the industrial conditions and the high cost of labour and material. No progress had been made with the Orsrères Power scheme, and in view of the present conditions, the company's interest in it might be disposed of. A final dividend of 5 per cent. per annum was paid on the ordinary share capital, leaving a carry-forward of £15,777.

REVIEWS

TONWARENERZEUGUNG. *By* Professor W. RUDOLPH. *Second edition. Pp.* 210. *Leipzig: Max Jänecke*, 1923. *Price* 4*s*. 3*d*.

This is a type of book which has long been popular in Germany, but has only lately been recognised in this country. It is one of a large series of small technical volumes, which are more than 'primers,' but not large enough to be 'handbooks.' They appear chiefly to be read by people who wish to gain rapidly a general idea of the technology of the industry concerned, without troubling themselves with a great amount of detail.

The present volume, which deals with the manufacture of clay-wares, is typical of others in the series. It commences with a very brief introduction, followed by a history of pottery manufacture, which occupies about one-tenth of the volume. Nearly half the volume is devoted to very brief notes on substances used in pottery manufacture, arranged under their respective elements, the latter being in alphabetical order, and the remainder of the volume is occupied with brief descriptions of various methods used in the manufacture of clay-wares.

The notes on each subject are so brief as to be of little or no value to manufacturers or users of pottery, or to chemical engineers engaged in the design or supply of machinery, kilns, etc. for these industries. The volume may, however, be useful as an elementary textbook if used by a good teacher, or as a "reader" for students of ceramics who wish to gain a greater familiarity with the German language.

In several instances the author shows a lack of acquaintance with recent investigations outside Germany, and he appears to favour the Schulze elutriator in preference to the much more accurate one devised by Schoene. He does not appear to have realised the misleading nature of the results of a "rational analysis.' There are unfortunate defects in a book by the Director of a State Pottery School. Colloids are described as substances which swell in water like glue, but no explanation of colloidal sols and gels or of their essential characteristics, is given. Yet plasticity is attributed to the formation of colloids by the action of water on clay! The constitutional formula he uses for kaolinite is an unusual one (though this is not stated), and that for sillimanite—the chief product of the calcination of kaolinite—cannot be derived from it in any simple manner. There is a copious index.

A. B. SEARLE

A TEXT BOOK OF INORGANIC CHEMISTRY. *By* G. S. NEWTH, F.I.C. *New and enlarged edition. Pp. xiii*+772. *London: Longmans, Green and Co.*, 1923. *Price* 8*s*.

It may be assumed that Newth's Inorganic Chemistry has been one of the most successful of such text-books. It will be remembered that the book is divided essentially into two sections: first, a consideration of the fundamental theory, and second, an encyclopædic account of descriptive chemistry. Throughout the tendency is to give definite statements: final conclusions rather than a review of the evidence upon which these conclusions are based. Thus the book loses something of the romance of chemistry and becomes dull and prosaic. It may also be questioned whether the modern teacher does not find that this divorce of theory and practice is wrong. Thus, for example, the underlying principles of the Haber synthetic-ammonia process are not dealt with; and in passing it may be said that there is no reference to the other modern methods, such as the Serpek process.

This didactic method requires rigid accuracy, and such statements as the following are misleading: "a temperature of −260° C. has been obtained, which is the lowest degree of cold ever reached"; "the exact ratio of the weights of an atom of hydrogen and oxygen is not known with certainty" (Burt and Edgar's work is not mentioned); no bismuth hydride is known; "Moissan's recent success in the isolation of fluorine"; carbon dioxide "is largely manufactured from these materials"—sulphuric acid and chalk. In many places the nomenclature and symbolisation are not those in common use to-day.

These, and similar errors of revision, suggest that the new edition is really only a reprint with additional chapters; which is hardly sufficient if the book is to maintain its position amongst modern text-books. Of the new chapters, that on the Phase Rule is on the whole good and deals well with some common difficulties; but it contains a bad statement (p. 171), that in the water diagram "at the (invariant) point z, *and at that point alone*, is ice in equilibrium with water." The diagram on p. 174 is not correct, for it does not show that, when such an unsaturated salt solution is cooled, ice first separates. The chapter on Atomic Structure is inadequate, omitting as it does all reference to the work of Bohr, Moseley and the Braggs; and having said (p. 186) that the nucleus contains "cementing" electrons, it necessarily follows that the statement (p. 187), "the atomic number also expresses the number of electrons in an atom" is wrong.

The revision might have been more thorough; but certain chapters, particularly of the introductory section, are very well written, and the book probably still remains the most satisfactory text-book available at this price.

A. WESTON

MARKET REPORT

This market report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.	£23-£25 per ton. Very firm with little available. Complete absence of German supplies.
Acid Hydrochloric	4s. per carboy.
Acid Nitric	£24 10s. per ton. No signs of improvement.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Steady demand. Continental inquiries more frequent.
Arsenic (White)	£70-£75 per ton. Market steady.
Bisulphite of Lime	£7 per ton. Packages extra.
Bleaching Powder	£10 10s. d/d. No change. Spot demand poor.
Calcium Chloride	£6 per ton d/d.
Copper Sulphate	£27 per ton. Somewhat firmer.
Potash Caustic, 88/90%	£35 per ton. Considerably advanced in value. No German supplies.
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton. Normal.
Soda Caustic, 76%	£20-£21 per ton. Demand good, especially for the Continent.
Soda Crystals	£5 5s. carr. paid. No change. Demand quite good.
Sod. Bicarbonate	£10 10s. per ton.
Sod. Acetate, 97/98%	£25 per ton.
Sod. Bisulphite Powder 60/62%	Ton lots: £19 .. 10 £19 10s. 5 £20 .. 2 £20 10s. 1 F.o.b. or f.o.r. London, 1-cwt. iron drums incl'ded
Sod. Chlorate	3d. per lb. Demand not quite so brisk with better supplies.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide	£15 conc. solid, carr. paid. Better demand.
Sod. Sulphite—	Ton lots.
Pea Crystals	£17 .. 2 £17 10s. 1 1-cwt. wooden kegs included.

RUBBER CHEMICALS

Antimony Sulphides—	
Golden	8d.-1s. 3d. per lb.
Crimson	1s. 7d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6½d. per lb.
Sulphur, Finest	£11 10s. per ton.
Arsenic Sulphide	2s. per lb.
Chromium Oxide	1s. 5d. per lb.
Lead Hyposulphite	8d. per lb.
Zinc Sulphides	7½d. per lb.
Carbon Bisulphide	£28 per ton.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Thiocarbanilide	2s. 6d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£10 per ton d/d.
Grey	£20 per ton d/d.
Liquor	9d. per gall 32° Tw.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. per gall. 24° Tw.
Red Liquor	1s. 3d. per gall. 14/15° Tw.
Wood Creosote	2s. 6d. per gall. unrefined. Lower prices, however, are asked in some quarters.
Wood Naphtha—	
Miscible	6s. 6d. per gall. 60% O.P.
Solvent	5s. per gall. 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead	£39 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 7d.-1s. 8d. per lb. No change.
Crude 60's	4s.-4s. 6d. per lb. Market firm.
Acid Cresylic—	
97/99	2s.-2s. 3d. More inquiry for prompt and forward delivery.
Pale 95%	1s. 10d.-2s. 2d. Market steady, with slightly improved inquiry.
Dark	1s. 6d.-1s. 11d. Moderate business passing.
Anthracene Paste, 40%	4d. per unit per cwt. Price still nominal.
Anthracene Oil—	
Strained	9⅝d.-11d. per gall. More inquiry. Supply limited.
Unstrained	9d. per gall.
Benzole—	
Crude 65's	1s. 1d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall.
Pure	2s.-2s. 3d. per gall. Fair inquiry.
Toluole—90%	1s. 9d.-1s. 11d. per gall. Fair demand.
Pure	2s.-2s. 6d. per gall. Little business moving.
Xylol	2s. 9d.-3s. 3d. per gall.
Creosote—	
Cresylic, 20/24%	11d.-1s. 1d. per gall.
Middle Oil	8¾d.-9½d. per gall. Market firm.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d.-9¼d. per gall.
Solvent, 90/160	1s. 5d.-1s. 9d. Market somewhat weaker.
Solvent, 90/190	1s. 6d.-1s. 7½d. per gall. Little business doing.
Naphthalene, Crude—	
Drained Creosote Salts	£5-£9 per ton. Supply still scarce. Good demand.
Whizzed or hot pressed	£10 15s.-£13 10s. per ton. Supply short.
Naphthalene—Crystals	£17 per ton.
Flaked	£16 per ton.

Pitch, Medium Soft	190s.-200s. per ton. Market steady.
Pyridine—90/140	11s.-12s. Fair enquiry.
Heavy	8s.-9s. Price nominal.

INTERMEDIATES AND DYES

Acetic Anhydride	1s. 5d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 7½d. lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. lb. 100% basis d/d.
Aluminium Chloride, anhydrous	1s. per lb. d/d.
Aniline Oil and Salts	9½d. per lb. naked at works.
Antimony Pentachlorine	1s. 1d. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlor Phenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
p-Dichlorbenzol	£55 per ton.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene—48/60	8d.-9d. naked at works
66/68	1s. 2d.-1s. 3d. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d. Packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Monochlorbenzol	£70 per ton.
a-Naphthol	2s. 9d. per lb.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d.-8d. per lb.
Nitronaphthalene	1s. per lb. d/d.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
Sod. Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	13s. ,, ,,
Amyl Acetate	2s. 6d. ,, ,,
Amyl Butyrate	8s. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol, melting point 21/22° C.	4s. 3d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehydo free from Chlorine	3s. ,, ,,
Benzyl Benzoate, 19.5° C.	3s. ,, ,,
Cinnamic Aldehyde—	
98/100% Natural	14s. 9d. ,, ,,
Coumarin	15s. 6d. ,, ,,
Citronellol	22s. 6d. ,, ,,
Citral, 100%	9s. 6d. ,, ,,
Ethyl Cinnamate	18s. 6d. ,, ,,
Ethyl Phthalate	4s. 3d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	7s. 6d. per lb.
Iso Eugenol	16s. 6d. ,, ,,
Linalol ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	22s. 6d. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Ketone	35s. ,, ,,
Musk Xylol	9s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	24s. 6d. ,, ,,

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil, Red Ship Brand	2s. 1d. per lb.
Bergamot Oil	12s. 6d. spot, 13s. 6d. forward.
Cananga Oil, Java	9s. per lb.
Cinnamon Oil, Leaf	4¼d. per oz.
Cassia Oil, 80/85%	8s. 3d. per lb.
Citronella Oil—	
Java, 85/90%	4s. per lb.
Ceylon	3s. 4½d. per lb.
Clove Oil	8s.-8s. 6d. per lb.
Eucalyptus Oil, 70/75%	1s. 9d. per lb.
Lavender Oil, Mont Blanc, 38/40%	13s. per lb.
Lemon Oil, spot	3s. per lb. Higher prices are asked for forward delivery.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet, spot	11s. 6d. Higher prices are asked for forward delivery.
Otto of Rose Oil—	
Anatolian	24s.
Bulgarian	26s.
Palma Rosa Oil	17s.
Peppermint Oil—	
English, Mitcham	80s. per lb.
Mayne County	13s. per lb.
Japanese	6s. 6d. per lb.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid Acetic, 80%	£50-£52 10s. per ton.
Acid Acetyl Salicylic	3s. 3d. per lb. In fair demand at previous quotation.
Acid Benzoic	2s. 3d. per lb. still quoted, but spot supplies are much shorter.
Acid Citric	1s. 8½d.-1s. 9d. per lb. Demand improving.
Acid Gallic	3s. per lb. for 2-cwt. lots, 3s. 3d. per lb. for 56 lb. lots.
Acid Pyrogallic, cryst.	5s. 9d. lb. Price advanced.
Acid Salicylic	2s. 2d.-2s. 6d. per lb. firmly held.
Acid Tannic	3s. 3d. per lb. for a good light quality.
Acid Tartaric	1s. 3d., less 5%. Demand continues to increase. Owing to the cutting off of supplies from Germany, the U.S.A. is reported to be buying largely from Italy. This has stiffened Italian prices, and raw materials still advancing,

	and a further rise in the price of the finished product must of necessity follow.
Amidol	9s. per lb.
Acetanilide	1s. 6d. per lb. Demand still poor.
Amidopyrin	14s. per lb.
Ammon. Benzoate	3s. 3d. per lb. Slightly higher.
Ammon. Carbonate B.P.	£37 10s. per ton.
Barbitone	17s. 6d. per lb. Higher prices are quoted by some holders.
Benzonaphthol	3s. 3d. per lb.
Bismuth Salts	Unchanged Steady market.
Bromides	Very firm. Will probably advance as foreign stocks become depleted.
Calcium Lactate	2s. 9d. per lb. for best English makes.
Chloral Hydrate	4s. per lb. Slightly weaker.
Guaiacol Carbonate	10s. per lb. is the present value. Higher prices being quoted on heavy demand from abroad.
Hexamine	4s. 6d. per lb. for present stock. This price will have to be advanced when stocks get lower, as the prices quoted from the Continent for forward delivery are on a much higher level.
Iron Ammon. Citrate	2s. 5d. per lb. for 1-cwt. lots. Market rather quiet.
Magnesium Oxide, Heavy	2s.-2s. 3d. per lb. Good demand.
Menthol	32s. per lb. for original cases. Smaller quantities 33s. lb.
Methyl Salicylate	2s. 6d.-2s. 7d. per lb. for glass containers.
Methyl Sulphonal	13s. 6d. per lb.
Mercurials	Slightly weaker on the reduction in the price of the metal.
Paraformaldehyde	4s. per lb.
Paraldehyde	1s. 7d.-1s. 8d. per lb. Very firmly held at this figure.
Phenacetin	6s. 6d. per lb. is the present advanced rate.
Phenazone	7s. per lb. would probably be accepted, although higher rates are expected in the future.
Phenolphthalein	5s. per lb. Unchanged.
Potass. Bitartrate—99/100% (Cream of Tartar)	98s. per cwt., less 2½%. Price tending to advance owing to continued rise in raw materials.
Potass. Iodide	15s. 8d. per lb. for cwt. lots. Good demand.
Potass. Permanganate	10d. per lb. still wanted.
Potass. Sulphoguaiacolate	5s. 6d. per lb. Firming up.
Quinine Sulphate	2s. 3d.-2s. 4d. Steady.
Resorcin	5s. per lb. Quiet at this figure.
Salol	2s. 9d. per lb. In short supply.
Silver Proteinate	10s. per lb.
Sod. Benzoate	2s. 3d. per lb. Very firm.
Sod. Citrate	U.S.P. quality 2s. 2d. per lb. for cwt. lots.
Sod. Hyposulphite—Photographic	£15-£17 per ton according to quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. per cwt. Demand poor.
Sod. Salicylate	2s. 5d. for Powder, 2s. 6d. for Crystal. Very firm at these figures, which are based on a lower price for phenol than the present market cost.
Sod. Sulphite, anhyd.	£27 10s.-£28 10s. per ton f.o.r. London, 1-cwt. wooden kegs included.
Sulphonal	13s. per lb.
Tartar Emetic, B.P.	1s. 3d. per lb. Demand small.
Thymol	18s. per lb. for White Crystals. A synthetic product is being offered at lower figures.

TRADE NOTE

Wages in the Heavy Chemical Trade

Workers in the heavy chemical trades are to vote this week on the employers' proposals to reduce wages. Some 50,000 workers are involved, the chief centres affected being London, Manchester, Birmingham, Leeds, Stafford, Newcastle, and large areas in North and South Wales. The employers insist on reducing the pay of shift workers by ½d. an hour. Two rates of pay are in force, time workers receiving 1s. per hour, and process or shift workers 1s. 2d. per hour. A meeting of the Joint Industrial Council for the Chemical Trades, representing both parties, will meet on April 19 at the Ministry of Labour.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, APRIL 20, 1923 No. 16

EDITORIAL

PROFESSOR MORGAN'S Review of the Synthetic Vat Colours by Professor Thorpe and Dr. Ingold, which appears in this issue, directs our attention to an interesting book and an important British industry. Professor Morgan's reference to Tyrian-purple caused us to turn to the book. There is a flavour attached to such names as Tyrian-purple and purple of Cassius which should be a valuable asset, and we are surprised that no enterprising advertiser converts to his own advantage a name which has such a history and romance as Tyrian-purple. Dibromo indigo which forms a large proportion of the colouring matter of the shellfish purple, can be made synthetically. But for every one who would buy dibromoindigo there must exist scores who would like to possess a fabric dyed with Tyrian-purple, and if judicious steps were taken it might for a season or two be the fashionable colour. The difficulties of the vat dye industry are, however, too great for an idle speculator to solve and too important to be neglected. We are glad to note that Professor Morgan will shortly deal with these in a serious manner in these columns, and we look forward to an article from him, knowing that such a contribution to the solution of the problem will deserve close consideration.

* * *

Justus von Liebig, who died fifty years ago, on April 18, 1873, at the age of seventy, is remembered to-day not only as the greatest chemist of his time, but as the author of theories of plant physiology that had far-reaching effects. Briefly, his main theory was that the plant built up its tissues solely from atmospheric carbon-dioxide and nitrogen, and that if it were supplied with the equivalent of its ash constituents, nothing else need be added. It is of interest to note that Liebig's pupil, Dr. J. G. Gilbert, in conjunction with Sir J. B. Lawes, started the series of experiments to test the validity of Liebig's theories that are still being continued at the Rothamsted Experimental Station.

THE ALKALI CENTENARY

The Centenary Celebration of the foundation of the Alkali Industry in this country directs our attention to an interesting and important piece of national history. To develop a new chemical manufacture, requires two kinds of talent which are very rarely found in one individual; scientific talent, capable of making use of chemical discoveries as they are made known and of improving and supplementing them, and business talent, sagacious in knowing when and where to start a business, how to organise sales, how to make the greatest profits in good times, and the smallest losses in bad times. The Alkali Industry in this country was founded so long ago that the scientific discoveries were vastly simpler then than they are at present.

It was not until the second half of the eighteenth century that the manufacture of chemicals became of importance, although prior to that time, alum, saltpetre, soap, white lead and some other pigments were made here and there in small quantities, and sulphuric acid was manufactured on a fairly large scale at Preston Pans by Roebuck since the year 1746. The investigations of Black, Cavendish and Rutherford, the discovery of oxygen by Priestley in 1774, the discovery of oxygen and chlorine by Scheele in the same year, and the establishment of chemistry as a science shortly afterwards by Lavoisier, brought the manufacture of chemical compounds into considerable prominence. It was in 1775 that the Académie des Sciences offered a prize of 2400 livres for the best process for producing soda from common salt, and during the last years of the century many French chemists devised processes of which the only one which need be mentioned here was that of Nicholas Leblanc, projected in 1787 and patented in 1791. This process was the treatment of salt by sulphuric acid to form sodium sulphate and hydrochloric acid; the operation was usually carried out in two stages represented by the following equations :—

$$NaCl+H_2SO_4 = NaHSO_4+HCl$$
$$NaCl+NaHSO_4 = Na_2SO_4+HCl$$

The hydrochloric acid, according to Leblanc's process, should be absorbed by ammonia, but in practice a good deal of it was allowed to escape into the air. The sodium sulphate or salt-cake was heated with carbon and limestone, and the operation, which like the first was conducted in two stages, is represented as follows :—

$$Na_2SO_4+C_4=Na_2S+4CO$$
$$Na_2S+CaCO_3=Na_2CO_3+CaS$$

The carbon monoxide was allowed to escape, the mixture of sodium carbonate and calcium sulphide was treated with water which dissolved the sodium carbonate, whilst the calcium sulphide was thrown away. Leblanc, although his process was once extensively used, did not receive the coveted prize and had a miserable end.

The Leblanc process was tried on a small scale by Mr. Losh, who started a works in Newcastle-on-Tyne in 1796, and by Tennant at the St. Rollox works about 1817, but it was not developed in this country until James Muspratt in 1823 commenced its manufacture on a serious scale at Liverpool.

Closely associated in these early days with the manufacture of alkali was the manufacture of bleaching powder. It was in 1785 that Berthollet first used chlorine water for bleaching purposes and three years later Charles Tennant, then a bleacher at Darnley, near Paisley, used a solution of chloride of lime for this purpose. He took out a patent for the manufacture of this "bleaching powder" in 1799 and commenced the manufacture of it at the St. Rollox works in Glasgow which he had founded in 1797. Bleaching powder fitted in with the manufacture of alkali very conveniently, for it was made by passing chlorine gas over dry slaked lime and the chlorine gas was made by treating manganese dioxide with hydrochloric acid, which is one of the by-products of the manufacture of salt cake. The various equations which epitomise these reactions are as follows :—

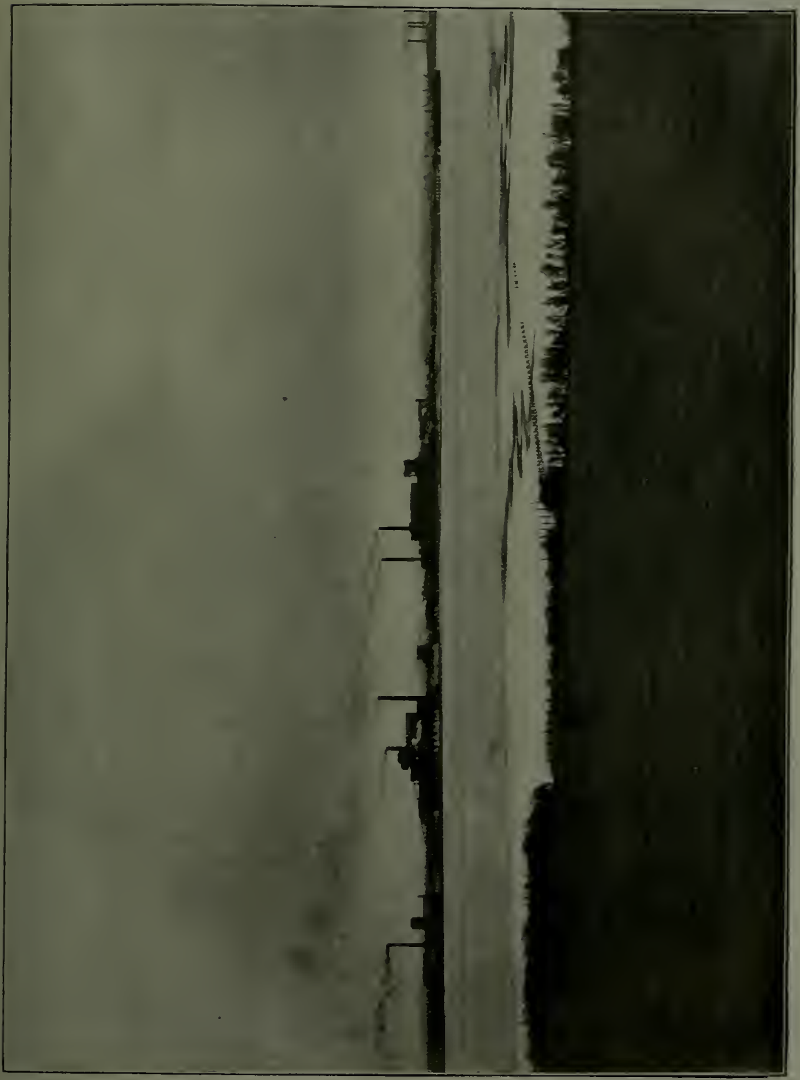
$$4HCl+MnO_2=Cl_2+MnCl_2+2H_2O$$
$$3Ca(OH)_2+2Cl_2=2Ca\left\{\begin{matrix}OH\\OCl\end{matrix}\right.+CaCl_2+2H_2O$$

where bleaching powder is considered to be a mixture of $Ca\left\{\begin{matrix}OH\\OCl\end{matrix}\right.$ and $CaCl_2$. The utilisation of by-products is, of course, essential to the economical manufacture of any chemical compound, and by combining the manufacture of alkali with that of bleaching powder the by-products left available were (1) a quantity of hydrochloric acid escaping into the air; (2) carbon monoxide from the black-ash process; (3) calcium sulphide; and (4) manganese chloride from the chlorine gas process. Some of these products were successfully dealt with in later years. Meanwhile, chemical works were from time to time started in various places; in 1809, Josiah C. Gamble commenced the manufacture of bleaching powder in Monaghan, and in 1815 he set up a works for the manufacture of this and sulphuric acid in Dublin; in 1820 Andreas Kurtz started the manufacture of chromate of potash in Manchester; and in 1823 John Mercer started a works for making dry stannate of soda in the same district. But an event of greater importance to the industry also took place in that year. The heavy salt tax which had greatly burdened the industry was repealed in 1823, and immediately thereafter James Muspratt saw the possibilities of the manufacture on a large scale of alkali in Lancashire in the vicinity of the salt deposits of Cheshire and the coalfields of Lancashire. James Muspratt was a manufacturer of prussiate of potash near Dublin who in 1822 came to Liverpool and started a small sulphuric acid factory there. The repeal of the salt tax gave him his opportunity and he took it. The manufacture under his management was prosperous, and in 1828 he was joined by Josias Gamble and the two set up a larger works at St. Helens. The partnership was dissolved after a couple of years. Muspratt set up a works at Newton near Liverpool, and Gamble remained in St. Helens. In 1836 Gamble and the Crosfields started another works at St. Helens for the manufacture of alkali, and about the year 1842 Andreas Kurtz began to work the Leblanc process in another works at St. Helens. The manufacture of alkali on a large scale soon showed the necessity for improvements and modifications, and many of these and some alternative processes were tried. Of the latter the ammonia-soda process is the most important. It was originally worked out and patented by Harrison G. Dyar and John Hemming in 1838 and depends on the decomposition of common salt by ammonia and carbon dioxide in accordance with the following equation :—

$$NH_3+CO_2+NaCl+H_2O=HNaCO_3+NH_4Cl$$

The process is carried out by passing carbon dioxide into a solution of salt and ammonia in water; the bicarbonate of soda being only slightly soluble crystallises out, and the mother liquor containing ammonium chloride is heated with lime forming calcium chloride and ammonia which is used again in the process. The calcium chloride is of value and can be purified and sold. Dyar and Hemming were not able to work the process economically, nor were Henry Deacon and William Pilkington who tried it in 1853 at Widnes, nor James Muspratt who tried it in his works at Newton about the same time, and it was not until 1855 that it was carried out on a large scale by Schlössing and Rolland near Paris. Not until Solway worked the process at Brussels in 1861 did it become profitable. Another alternative process formerly in use was the Hargreaves' process which consisted in treating salt in a kiln with sulphur dioxide, steam and air, so as to produce the following action :—

$$2NaCl+SO_2+H_2O+O=Na_2SO_4+2HCl$$



FLEETWOOD AMMONIA-SODA WORKS

The Leblanc process had disadvantages, of which the loss of hydrochloric acid escaping into the air and the loss of sulphur in the form of calcium sulphide were very important. The first of these defects was remedied by William Gossage, an alkali maker at Stoke Prior, in Worcestershire, who in 1836 patented a condensing tower containing lumps of coke down which water descended and up which the gases containing the hydrochloric acid rose. The water absorbed the hydrochloric acid, effecting a saving of money and reducing very much the destructive effect of the acid vapours on the vegetation of the vicinity. The Gossage tower was extremely successful and widely adopted. In the following year, 1837, Gossage took out a patent for a process for avoiding the waste of sulphur. He treated the calcium sulphide with carbonic acid, which formed calcium carbonate and sulphuretted hydrogen; the latter was burned to form sulphur dioxide, which was used, directly or indirectly, to decompose a further quantity of salt.

Another wasteful process studied by Gossage about the same time was the manufacture of chlorine by treating manganese dioxide by hydrochloric acid. In 1837 he patented a process for treating the resulting manganese chloride with hydrated lime, so producing calcium chloride and a hydrate of manganese which readily absorbs oxygen from the air and forms a hydrated dioxide available for succeeding operations. A number of works for the manufacture of sulphuric acid, alkali, bleaching powder, alum and other "heavy chemicals" grew up in Newcastle, Glasgow, St. Helens, Widnes and other Lancashire towns, and the names of Tennant, Muspratt, Brock, Gamble, Allhusen, Kurtz, Gossage, Deacon, Spence, Gaskell and Pilkington are well known as founders of the chemical industry in this country, and some of them left sons and grandsons to carry on the traditions they inherited, in a manner worthy of their distinguished forbears.

At this interval of time some little research is demanded of anyone who tries to find out why some of the early processes were not commercially successful. It was so long ago as 1831 that Peregrine Phillips proposed the manufacture of sulphuric acid by passing sulphurous acid and air over finely divided platinum, and a detailed account of his methods would doubtless be instructive. Exactly why Gossage's method of treating the manganese chloride residues was only partially successful is probably known to many, but the reason is not obvious to one who rapidly explores only the main features in this bit of history. It is, however, beyond question that, prior to the year 1867, the recovery of manganese from the liquors in the manufacture was expensive and unsatisfactory. In that year Mr. Walter Weldon patented a process, first carried out at Messrs. Gamble's works at St. Helens, which effected a revolution in the industry. This process enabled more than ninety per cent. of the previously wasted manganese to be recovered, and speedily brought the price of bleaching powder down by no less than £6 per ton. According to M. Dumas, "By Mr. Weldon's invention every sheet of paper and every yard of calico has been cheapened throughout the world." His process is to mix the solution of manganese chloride with milk of lime, forming manganese hydroxide, and then to heat the mixture to a temperature of 55° C. and blow air through it. The manganese dioxide, mixed with a little lime, settles at the bottom of the tank, and is known as "manganese mud"; this is washed with water, allowed to settle, pressed to a cake and used for the manufacture of chlorine. The difficulties in the industrial application of the ammonia-soda process of Dyar and Hemming, and how they were overcome by Solvay, belong to another chapter of the history of applied chemistry.

The disinfecting properties of the manganates and permanganates were noticed by Hofmann and the manufacture of them undertaken by Condy in 1856. Mr. Condy seems to have been somewhat of an optimist, for he solemnly recommended the use of his disinfecting fluid to wine-tasters for refreshing their palates. This fashion, if it ever prevailed, is not now frequently observed in this country. The history of the manufacture of chemicals recalls occasionally some old-fashioned practices. The manufacture of tungstate of soda and its use to make fabrics non-inflammable became unduly important in the middle of the nineteenth century, because, as Professor Hofmann observed, the ladies wore flimsy clothes which often caught fire, and "the fashion of expanding their attire with steel hoops increases the risks of these terrible casualties." The deaths from this cause were certainly remarkably frequent.

Naturally, the makers of alkali, who were large users of sulphuric acid, undertook the manufacture of it, and, indeed, the two industries were very closely identified. The substitution of iron pyrites for the Sicilian sulphur as basis for the sulphuric acid was an old practice, but it received a great impetus when, in 1838, the Neapolitan government interfered with the free exportation of sulphur from Sicily. Mr. Gossage showed how to recover copper from the pyrites, and this formed a connexion between the alkali industry and the copper industry.

It may well have been the great growth of the heavy chemical industry and its great prosperity which prevented the British chemical manufacturers from developing the organic side also. It would have been possible. Michael Faraday discovered benzene, or, as he called it, "bicarburet of hydrogen," in 1825, and Charles Mansfield was the first to prepare it from coal-tar in considerable quantities; this was in 1848.

(*To be continued*)

CHEMISTRY IN MEDIÆVAL ISLAM

By E. J. HOLMYARD

Head of the Science Department, Clifton College

It is a matter of common observation that adages usually exist in pairs, one member of the pair uncompromisingly contradicting the other —in appearance at least, if not in spirit. Thus Goethe's pregnant statement, "The history of a science is the science itself," can be countered with Kopp's opinion that "the history of alchemy is the history of an error." We should, perhaps, expect the poet to have a fuller grasp of philosophic truth, and there can indeed be no doubt that Kopp's judgment was shallow and lacking in insight; it connotes an ingenuous belief in the absolute value of scientific theories and hypotheses, partly accounted for by the vast development of science in the nineteenth century, but rather rudely shaken in the last few years by the elaboration of the theory of relativity. If we adopt the attitude succinctly expressed by Sir J. J. Thomson at Cambridge, in January—"theories are tools and not creeds"—we need make no apology for treating the history of science as a serious study, worthy of the same meticulous care and unsparing devotion as researches in the laboratory.

For five or six hundred years—from the seventh to the twelfth century A.D.—chemistry was almost a monopoly of the savants of Islam, who took it over from the Greek school at Alexandria at the beginning of the period and handed it on to mediæval Europe at the end. It is difficult to estimate accurately the extent and value of the contributions made to chemistry by Islam, but, in the words of one best qualified to judge, Prof. E. G. Browne (*Arabian Medicine*, p. 15), "it was in the domains of chemistry and *materia medica* that the Arabs added most to the body of scientific doctrine which they inherited from the Greeks." No serious attempt has hitherto been made, however, to study adequately the large number of Arabic chemical treatises which have come down to us, many of them of the greatest interest and importance.

The study of chemistry seems to have originated in Islam with the Ummayyad prince Khalid ibn Yazid ibn Mu'awiya (died 704 A.D.), who was taught the science by an Alexandrian monk named Marianus. Khalid, however, was more interested in the mystical side of chemistry than in its true scientific aspect, and from those fragments of his chemical verse which are extant, it is clear that he has no claims to serious consideration as a chemist. He had, nevertheless, the great merit of making chemistry fashionable, and among those whom he led to its study was a youth who afterwards became famous as Geber, or, to give him his full name, Abu Musa Jabir ibn Hayyan the Sufi. The question whether the Latin Geber is to be identified with the Arabic Jabir I have discussed elsewhere (*Nature*, Feb. 10, 1923). There seems to be no valid reason for denying this identity, as the content of the Latin works is very little different from that of certain Arabic works ascribed to Jabir, the authenticity of which has hitherto been undisputed. I hope to discuss the whole matter fully in a forthcoming work on the *Chemical Theory and Practice of the Arabs* (Gibb Memorial Trust Fund Publications).

The birthplace of Jabir is uncertain. He is known to have lived at Kufa, and is therefore sometimes called Al-Kufi, but it is possible that he was born at Harran in Mesopotamia, at that time a celebrated seat of learning and the centre of the Sabæan sect. He received a thorough training in philosophy and medicine, and attained to a position of eminence under the Caliph Harun al-Rashid (786–808 A.D.).

As Jabir's chemical views were largely coloured by the general trend of contemporary philosophic thought, it will be well for us to obtain some knowledge of the latter before proceeding to consider his chemistry in detail. Muslim philosophy was largely Aristotelian in character, but the critics had often failed to distinguish between theories of Aristotle himself and those of his commentators, among whom Alexander of Aphrodisias (second century A.D.) had most influence. Many works, again, which we now consider to be falsely attributed to Aristotle were in those days accepted as genuine, while the whole philosophic outlook of the Arabs was infused with the Neo-Platonism of Porphyry and Plotinus. Matters were still further confused by the tendency shown by the Alexandrians and the Sabæans to syncretism, which caused much legendary matter to be accepted as historically true. The leanings to mysticism which Geber and other chemists show is also probably to be attributed to Neo-Platonic influences.

However, the main features of what we may call the scientific philosophy of Islam are fairly clear. The first postulate is the unity of matter. All substances are composed of a *prima materia*, the Aristotelian ὕλη, but the *prima materia* has no actual existence unless it is united to Form, which is of two varieties, Corporeal Form and Specific Form. "Abstract Body" is the result of the combination of the *prima materia* with Corporeal Form, whilst the addition of Specific Form to Body in the Abstract gives rise to an Individual Body. The simplest kinds of Specific Form are those which, in combination with Body in the Abstract, give rise to the form Aristotelian "elements," Fire, Air, Water and Earth. All other substances are composed of these Elements in various proportions and combinations, but the *prima materia* is the same in all.

Abstract Body combined with the *metallic* Specific Form gives rise to the metals, which are therefore essentially all of one species. The existence of several different *varieties* of metals such as gold, silver, copper, lead and so on is explained by assuming that metals other than gold have become contaminated with certain accidental (*i.e.*, unessential) qualities; removal of these qualities from an "imperfect" metal will convert the latter into gold.

In common with all thinking men of the time, the Arabs believed in astrology, and considered that the planets exercised an influence upon the metals; but it is noteworthy that this belief, while acknowledged, is almost always relegated to the background by the chief chemists of Islam, who seem to have been men of an eminently practical habit of mind. They realised that no great advance can be made in science without the foundation of experimental fact, and one of the greatest of them, Maslima al-Majriti (died 1007 A.D.), tersely says:—"As to transmutation, there can be but one proof of that, namely, experimental"—and this although he himself firmly believed that transmutation was, *a priori*, possible.

Jabir ibn Hayyan is conspicuous at once for his tremendous energy, which embraced philosophy, natural history and medicine as well as chemistry, and was sufficient even to enable him to keep abreast of the latest developments in mystical theology—the system of Sufi-ism, founded a few years earlier by Abu Hashim of Kufa. Jabir wrote many books, at least fifty of which are extant. The most important of these, from a chemical point of view, are the *Great Book of Properties*, which exists in a unique manuscript in the British Museum, and the *One Hundred and Twelve Books*, unfortunately known to us only in fragmentary quotations. His contributions to chemistry (excluding those mentioned only in the Latin works) were very numerous, both in theory and in practice. His theory that metals are composed of mercury and sulphur, enunciated in the first book of the *One Hundred and Twelve Books* (quoted by Aidamir al-Jildaki in Vol. I. of his *Nihāyat at-Talab*, Cairo MS.) proved extremely fruitful and is a definite attempt to construct a more "chemical" theory than the philosophic Aristotelian one mentioned above. Jabir appears to have regarded mercury as the nearest approach among sublunary bodies to the *prima materia*, sulphur representing the combustible principle.

His views on the structure of mercuric sulphide, which I have already quoted in *Nature* (Feb. 10), are so remarkable, and bear such clear witness to the fine calibre of his mind, that I will give them again here. "When mercury and sulphur combine to form one single substance, it has been thought that they have essentially changed and that an entirely new substance is formed. The fact is otherwise, however. Both the mercury and the sulphur retain their own natures—all that has happened is that their parts have become attenuated and in close approximation to one another, so that to the eye the product appears uniform. But if one could find an apparatus to separate the particles of one sort from those of the other, it would be apparent that each of them has remained in its own permanent natural form and has not been transmuted or changed. We say, indeed, that such transmutation is not possible for natural philosophers." On the practical side Jabir's researches ranged far and wide, and it is worthy of note that they do not confine themselves, as do those of so many early chemists, to attempts at transmutation. He describes the preparation of various salts, such as white lead (by precipitating a solution of lead acetate with sodium carbonate) and cinnabar, the reduction of metallic calces, the use of alum as a mordant, methods of waterproofing cloth and of rendering it fire-proof, details of dyeing, pharmaceutical uses of compounds both organic and inorganic, and he discusses various operations such as calcination and distillation.

In his Book of the *Divine Science and Philosophical Wisdom* (Cairo MS.), he explains the nature and objects of chemistry and gives rules for the guidance of those who would study it. He says that chemistry is a branch of natural science, and that the chemist should strive to follow Nature's guidance; patience and continued practice are necessary, and it is advisable to acquire a thorough knowledge of the chemistry of mineral bodies before proceeding to the investigation of substances from plants and animals. According to one of his commentators, he deserved the name Jabir, for it was he who re-organised (*jabara*) the science of chemistry and put it on a firm basis.

He became involved in the fall of the Barmekide family, and had to fly to Kufa, where he spent many years in retirement, if not in definite concealment.

The chemical tradition was carried on by Abu Bekr Muhammad ibn-Zakariyya al-Rāzī (Rhazes), who died in 923 or 932, Maslima al-Majriti (died 1007), Ibn Arfa' Ra's (died 1197), Abu'l-Qasim Muhammad ibn Ahmad al-'Iraqi (about 1300), Al-Tughra'i (died 1121) and Aidamir al-Jildaki (died about 1360 A.D.) Works of all of these are extant, and additional information concerning chemistry in Islam is to be found in the *Kitab al-Fihrist* of Al-Nadim, in the *Prolegomena* of Ibn Khaldun's *History* in the biographical dictionaries of Hajji Khalifa, Ibn Abi Usaibi'a, and Al-Qifti, and in the encyclopædias of the Brethren of Purity and of Al-Qazwini, Al-Safadi, etc.

A system of chemistry, in which the main theory is that of the transmutation of the metals, naturally lent itself to charlatanry, and we find many amusing anecdotes on the frauds of alchemists in the popular literature. Thus Al-Janbari relates that a Persian impostor came to Damascus and, having filed into small pieces a thousand gold dinars, made the bits up into balls with fish-glue, flour and powdered charcoal. He then disguised himself as a dervish and sold the balls for a few pence to a druggist, under the name of *Tabarmaq of Khorassan*. He next clothed himself in a rich habit and made the acquaintance of the vizier, to whom he represented himself as an accomplished alchemist. The vizier presented him to the Sultan, who expressed a desire to see a transmutation. The charlatan wrote out a formula in which, among other drugs, Tabarmaq of Khorassan was indicated, to the weight of 100 mithgals. All the other chemicals were obtained easily, but a protracted search had to be made for the Tabarmaq. At last it was obtained from a druggist who said a dervish had sold it him. Needless to say, the experiment proved very successful; the Sultan was delighted, and wished to repeat the operation. However, no more Tabarmaq was to be found in Damascus, but the Persian said he knew a cave in Khorassan where it was to be found in abundance. So the Sultan equipped him with every requirement for the journey and gave him a large sum of money, after which he set out—and never returned.

Scepticism as to the possibility of transmutation arose at a very early date. Jabir himself, we are told by Al-Jildaki, was confronted with no little unbelief, and criticism of the transmutation theory assumed formidable proportions with the great Muslim philosopher Ibn Sina (Avicenna) in the tenth century A.D. Avicenna's attitude towards chemistry has not yet been thoroughly established, but as far as I can gather it seems to be that while he did not altogether rule out the possibility of transmutation, he considered that the theory of the unity of the metallic substance in the various metals was certainly inadequate and probably very wide of the truth. This is remarkable in view of the fact that his philosophy was essentially Aristotelian and Neo-Platonic.

The celebrated vizier Al-Tughra'i took up the cudgels on behalf of transmutation, but his arguments—mostly of a scholastic nature—are unconvincing, especially since he makes scarcely any reference to experimental work, for which he had little time, owing to the pressure of his ministerial duties. Al-Jildaki sums him up well when he says :—" Tughra'i was a man of exceptionally brilliant mind, but he carried out very little experimental work, and this renders his writings inaccurate."

Ibn Khaldun, Islam's greatest philosophic historian (died 1406), devotes several pages to alchemy in the Prolegomena to his History. He says :—" The object of the science of chemistry is to obtain a substance which may be employed, by suitable experimental methods, to cause the production in perfection of gold and silver. . . . The chemists make experiments on all sorts of things, after having discovered their temperaments and virtues, in the hope that chance may cause them to come across the substance possessing the property they seek. Not confining themselves to minerals, they even examine substances obtained from living organisms, and work on bones, feathers, hair, eggs and excrement.

" Chemistry also indicates the procedure, the object of which is to cause this substance (the transmuting agent) to pass from potentiality to actuality; as, for example, the resolution of bodies into their constituents by means of sublimation, distillation, solidification . . . . levigation . . . ., etc.

" Chemists maintain that they prepare by all these operations a natural body to which they give the name of *El-Iksir* and which, projected upon a mineral body such as lead, tin or copper, converts it into pure gold (under suitable conditions).

" In the obscure and enigmatical terminology of this art, the Elixir is called the *soul* and the substance upon which it is projected is called the body . . . . From ancient times up to our own day, men have not ceased to write on chemistry, and sometimes, even, books on chemistry have been published under the names of persons who never took any part in it."

Ibn Khaldun's last remark is very true, for instances of pseudepigraphy are numerous. Fortunately, the false works can usually be easily recognised by internal evidence. Thus, when one finds in an Epistle (MS. kindly lent me by Mr. A. G. Ellis) attributed to Mary the Copt, a conversation between the authoress and Jabir ibn Haiyan—who lived several hundred years later—one has no difficulty in deciding that the work is pseudepigraphical. However, the problem is not always as easy as this.

A further difficulty in the study of Arabic chemical manuscripts is that, as Ibn Khaldun says, the terminology is obscure, or, rather, technical. The lexicographers have little use for words which do not occur in the literary language, so that one has very largely to construct one's own dictionary. The few authors, such as Abu'l-Qasim al-'Iraqi, who give vocabularies are therefore invaluable; it is a matter for regret that there is no mediæval Muslim Beilstein, Thorpe, Richter or Watts !

A source of information on Arabic chemistry that up to the present has not been tapped is in the numerous collections of recipes that are scattered throughout the great libraries. These, the work very often of nameless authors, occasionally contain matter which more famous chemists would not deign to mention. Through the courtesy of the Librarian to the Pope, I have been able to have photographs made of one of these books which is preserved in the Vatican Library, and have found in it a good deal of interesting material. The whole subject, however, bristles with difficulties, and years of hard work will be necessary to elucidate properly the development of chemistry in Islam. The great need is the publication of texts—a need which, in these days when the setting up of Arabic type is almost prohibitive, is likely to remain unsatisfied. A study of the available material—original manuscripts, notices in Muslim history and encyclopædias, and the books and papers of Berthelot, Stapleton, Wiedemann and Carra de Vaux—has led me to the following conclusions, which, however, must be regarded as provisional only and liable to modification:—

1. Chemistry at the time when Muhammadan scientists first undertook its study presented three distinct aspects, the philosophical, the practical and the mystical. There was practically no correlation between the first two, and the latter formed a noxious jungle favoured by the unhealthy intellectual atmosphere of Alexandria. Khalid may be said to have lost himself in the jungle, but Jabir ibn Hayyan cut a way through it and made valiant and to some extent successful efforts to construct a coherent scientific method based on experimental facts interpreted in the light of contemporary philosophy. The Persian Al-Rāzī (Rhazes) was much more of an empiricist and acquired merit through his patient collection and orderly arrangement of facts and observations; he made no advance in chemical theory, and indeed as a physician his main interest in chemistry was from a pharmaceutical point of view. Except that the two men were as dissimilar as possible in character and disposition, Al-Rāzī might be called the Paracelsus of Islam.

2. It appears to me incontrovertible that in Islam chemistry was first elevated to the rank of a definite science and its theory and practice welded into a homogeneous whole.

3. The chemists of Islam, even if they did not invent that procedure which we now call scientific method, were certainly the first to apply it to chemistry.

4. Muhammadan chemistry is astonishingly matter-of-fact and free from magic and supernaturalism. It is quite definitely regarded as a branch of natural philosophy, distinct from and by no means a handmaiden to physics and medicine.

5. In passing to Europe *via* Spain, Muhammadan chemistry, whilst contributing to the general renaissance of science in the thirteenth century, lost a great deal. European chemistry of the fifteenth century—and possibly of the sixteenth—was not so far advanced as Arabic chemistry in the twelfth.

6. The phlogiston theory is a direct evolution of the sulphur-mercury theory of metals first formulated by Jabir ibn Hayyan.

These are no small achievements, and they were made in an age when science was not the powerful force in life which it is at present, and when chemists were regarded with a contemptuous pity at best, and often went in fear of their lives. The attitude of men of letters towards the chemist is, after all, not so very different now from what it was when Mas'udi (died *c.* 956) wrote :—" May Allah preserve me from applying myself to researches which enfeeble the brain, yellow the skin and ruin the sight, in the midst of the vapours of sublimation and the foul emanations from vitriol and other minerals ! "

THE PRINCIPLES OF TRANSFERENCE OF HEAT

By GEOFFREY J. GREENFIELD, S.M., A.I.C.

A great majority of processes in chemical industries involve the transference of heat from one body to another. Every boiler, still, heater, cooler, heat exchanger, and furnace presents a phase of this problem, which is therefore one of wide interest. Heat is carried from one point to another by one of three methods, viz. :—

Convection,
Conduction,
Radiation,

each of which we will consider separately.

Convection

The general effect of convection is that when heat is added to one portion of a fluid (whether liquid or gas), currents are set up in the fluid, so that in a very short time the whole mass is again at a uniform temperature. This time is all the shorter if the fluid is already in motion (*e.g.*, flowing through a pipe). Thus, in dealing with the practical transfer of heat, it is safe to assume that, once the heat is introduced into a fluid, it is rapidly distributed all through the mass.

Conduction

Transfer by conduction and by radiation, however, require a deeper consideration. We meet with conduction first in passing heat through a solid body—*e.g.*, a furnace wall (see Fig. 1). The quantity of heat which passes through the wall, from the hot side (tempera-

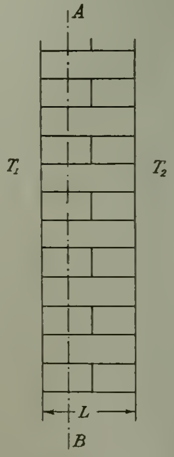


FIG. 1.

ture, T_1° F.) to the cold side (temperature, T_2° F.) in a given time, is the point of interest.

Let us compare the flow of heat through this wall with the flow of electricity along a wire. The rate of flow (B.T.U. per hour for the heat, amperes for the electricity) will be proportional to the driving force, or potential difference (degrees temperature difference for the heat, volts for the electricity) and inversely proportional to the resistance offered by the conductor. The electrical resistance of the wire is equal to

$$\frac{\text{length of wire}}{\text{cross-sectional area of wire} \times \text{specific electrical conductivity.}}$$

This is fairly obvious, since, the longer the wire, the more resistance will it offer; while the stouter it is, the more room is there for the electricity to flow. The "specific electrical conductivity" is a property of the substance of which the wire is made.

The same reasoning will be applied to the heat resistance of the wall. The length of the path which the heat has to travel is the thickness of the wall, L. The cross-sectional area is the area of a section AB, at right-angles to the plane of this paper in Fig. 1. The specific electrical conductivity of the above formula will be replaced by the specific heat conductivity, or coefficient of heat transfer. Thus, if

Q=amount of heat transferred (B.T.U.)
θ=time (hours)
A=area of the section AB, through which the heat flows (sq. feet)
L=thickness of wall (feet)
R=resistance of wall
k=coefficient of heat transfer
ΔT=temperature drop through the wall$=T_1-T_2$

then $R=\dfrac{L}{Ak}$

and $\dfrac{Q}{\theta}$ (rate of flow) $=\dfrac{\Delta T \text{ (driving force)}}{R \text{ (resistance)}}$

$$=\frac{kA\Delta T}{L} \quad . \quad . \quad . \quad (1)$$

This is the fundamental equation for the conduction of heat. The quantity k, the coefficient of heat transfer, is a property of the substance of which the wall is built.*

Film Concept

When a liquid or a gas is in contact with a solid surface, it behaves as though there were a stationary film, or skin, of the fluid adhering to the solid, notwithstanding that the body of the fluid may be in motion. To picture this the reader may conduct the following experiment, choosing a place with as little draught as possible. Light a cigarette, or a pipe; having taken a good "draw," quickly move the pipe to the surface of the table, holding the mouthpiece, inclined at 20° or 30° with the horizontal, in contact with that surface. In about ten seconds some smoke will have come out of it. and will rest in a little cloud on the table, Very gently remove the hand and the pipe, and the cloud will rest, almost stationary, for some time, being gradually moved by the convection currents above it. In a little while these currents will disperse it, and you will be surprised to find that it has been able to remain so still underneath such currents. If you blow upon the cloud you can see that, when the air is in motion relative to the table, the stationary film is soon reduced from several millimetres to a very thin layer. This is a very crude and simple experiment, and, to make it work properly, there should be a tablecloth on the table.

By carefully devised experiments, in which convection currents have been absolutely eliminated, it has been shown that liquids, and more especially gases, are very bad *conductors* of heat, much worse than most solids. This being so, it is evident that, in the general problem of the transference of heat *from* one fluid, *through* a solid wall, *to* another fluid, as in boilers, oil coolers, condensers, etc., *the fluid films will offer as much resistance as the solid walls, and often more.*

In Fig. 2, where, of course, the thickness of the air films has been vastly exaggerated, this idea is illustrated. The air on the hot side is maintained, by convection currents, at an even temperature T_1, and that on the cold side at an even temperature T_2. Heat flows from the hotter body of air to the colder, and its passage is opposed by three resistances in series, viz.:—

(1) The air film on the hot side.
(2) The solid wall.
(3) The air film on the cold side.

To each of these equation 1 applies. In the case of the film resistances, we do not know the value of the thickness, L. Indeed, there is not actually a definite line of demarcation between the stationary and the moving part of the gas. So, in dealing with this type of resistance, it is convenient to replace $\frac{k}{L}$ by a new symbol, h, which we may term the "film coefficient." This will be affected by everything which affects the thickness of the film, such as the velocity of the body of the fluid, the viscosity of the fluid (which, for any particular fluid, is a function of the temperature), and the shape of the solid.

Before going into the conditions affecting the value of the film coefficient, it will be well to consider how to deal with cases such as that of Figure 2, where the flow of heat is met by several resistances in series, and where the temperatures at the intermediate boundaries are not known.

---

* Care should be taken to notice in what units the conductivity is expressed. In the following pages all values given have the dimensions, $\dfrac{\text{B.T.U.} \times \text{ft. thickness}}{\text{sq. ft.} \times {}^\circ\text{F. temp. diff.}}$ and film coefficients (see later) $\dfrac{\text{B.T.U.}}{\text{sq. ft.} \times {}^\circ\text{F. temp. diff.}}$ When values are available in continental units (gr.-cals., cms. and ° C.), they may be converted to English units by multiplying by 242 (for conductivity) and by 7370 (for film coefficients).

The analogy between flow of heat and flow of electricity being so close, we may follow it a little further. For a number of electrical resistances in series,

$$R = r_1 + r_2 + r_3 + \text{etc.}$$

Similarly for heat resistances,

$$\frac{L}{kA} = \frac{l_1}{k_1A_1} + \frac{l_2}{k_2A_2} + \frac{l_3}{k_3A_3} + \text{etc.} \quad . \quad . \quad (2)$$

Usually (see Fig. 2) we know the temperatures at the beginning and end of the path, T_1 and T_2, but not those at the junctions of the component resistances, T_3 and T_4, so that it is convenient to use an *overall* coefficient, H, in the equation $\frac{Q}{\theta} = HA_{av}\Delta T$

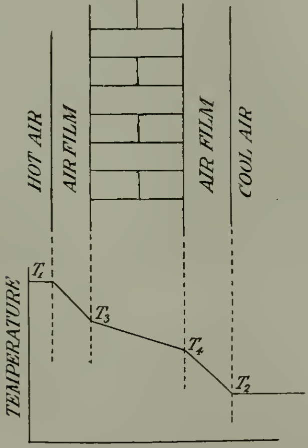

FIG. 2.

where A_{av} is the average area through which the heat flows, in cases where the area varies, as it will between the inner and outer surfaces of a circular, lagged pipe. This overall coefficient will be calculated from equation 2. The first and third resistances are films, so that l_1 and l_3 are unknown, and since $L = l_1 + l_2 + l_3$, therefore L is unknown. Substituting, therefore, H for $\frac{k}{L}$, h_1 for $\frac{k_1}{l_1}$, and h_3 for $\frac{k_3}{l_3}$, we have

$$\frac{1}{HA_{av}} = \frac{1}{h_1A_1} + \frac{l_2}{k_2A_2} + \frac{1}{h_3A_3} \quad . \quad . \quad . \quad (3)$$

from which, if we know the quantities on the right-hand side of the equation, we can find the value of HA_{av}, and substitute it directly in the heat flow equation.

Utility of the Film Concept

A great deal of work has been done on those problems of heat transfer which are of practical importance, but efforts have often been directed to establishing an *overall* coefficient. That the film concept is more likely to lead to useful results can easily be shown. Consider, say, the partial condenser of a still, in which feed liquor flows inside pipes, and takes heat from the vapours which condense outside the pipes. The three resistances here are :—

(1) Vapour film.
(2) Solid wall of pipe.
(3) Liquid film.

One's first impulse, if studying the overall coefficient, would be to seek some relation between it and the liquor velocity. If we double the liquor velocity, clearly the thickness of the liquid film will be reduced. Experiment shows that it is not quite halved, but it is at least reasonable to expect the film thickness to be proportional to some power of the velocity Thus, we have changed one of our three resistances, while the other two have remained unchanged ; so that any attempt to establish a relation between the overall coefficient and the liquor velocity will yield a result of very limited applicability. Such a relation, for instance, established for an ammonia still, where the vapour is a mixture of steam and ammonia, could not justly be applied to the design of an oil still ; nor, if determined for a condenser with copper tubes, could it be applied to one with aluminium tubes. But if we can find relations between the *film* coefficients and the variables affecting them, these will have a wider applicability.

Dominating Effect of Film Resistances

The predominance of film resistances over solid resistances is shown by the following example, chosen at random. The values of the coefficients used will be discussed later, and for the moment must be taken for granted by the reader.

In the liquor heater connected with the saturator of a certain plant for the direct recovery of ammonia from coal gas, the following conditions prevail :—

Temp. of entering liquor = 172° F.
Temp. of leaving liquor = 214° F.
Temp. of steam = 366° F.

Thickness of copper heating tubes = 0·165 in., 0.014 ft.

To protect the copper from the action of sulphuric acid, it is proposed to sheath the tubes in lead, $\frac{1}{8}$ in. thick (=·0104 ft.). What decrease in efficiency will occur ?

(*To be continued*)

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

Mr. E. Kilburn Scott's Cantor Lectures

at the Royal Society of Arts should remind us that, although the world is greatly overstocked with plant for producing nitrates from the air as a result of the war, the demand is increasing so rapidly that this condition of affairs cannot last. In ten years the demand for nitrates for non-military purposes has doubled. It would admittedly be difficult to work any of the arc processes in England at the present time, however desirable it might be from the point of view of national security; but, as Mr. Scott pointed out, the available water power in Canada and New Zealand is as large and as easily accessible as any in Europe. The great variety of processes shows clearly, I think, that the design of plant is very far from the goal to which it will ultimately tend. Perhaps the most interesting part of the first lecture dealt with the new Swiss plant, in which the amount of gases combined has been raised to 2½ or 3 per cent.; other improvements have resulted in the elimination of the alkali tower, whilst the yield is 75 grams of nitric acid per kilowatt hour. I shall look forward to hearing the remaining two lectures in the series.

Chemical Engineering

These lectures are of particular interest to those who feel that we cannot continue to do without the chemical engineer in this country. Where raw material costs nothing, the question of power is of supreme importance. If our industrial chemists are to make a success of nitrogen plant at home or in the Empire, they must be willing and able to meet the producers of electrical power halfway. They must be prepared to utilise off-peak power, to design their furnaces to give a high power factor and utilise three-phase current where necessary. A dialogue between an engineer (knowing no chemistry) and a chemist (knowing nothing of electrical machinery) engaged in designing an arc furnace would prove interesting reading; but would the result be satisfactory? I know that "fancy plant" is anathema in many works. The marine store dealer may meet the need where a small and uncertain demand for a chemical of restricted use has to be satisfied. But in such an industry as this special plant is indispensable, and Mr. Scott has shown us how great is the improvement brought about by improvements in design. It is remarkable, however, that the yield of the best modern plants does not exceed by 50 per cent. that obtained by Lord Rayleigh in his pioneer work on nitrogen fixation.

The Centenary of the Alkali Industry

is being celebrated as these lines go to press. What a wonderful record could be written of these 100 years, and what an interesting share the Muspratt family have had in the work. In 1650, in the ancient and at that time leading city of Winchester, there was a Thomas Muspratt who was the Mayor. From him there was directly descended the James Muspratt who went over and settled in Ireland and was the great-grandfather of the present Chairman of the United Alkali Company, Ltd. He had two sons; one of them, John Petty Muspratt, who was a director of the East India Company, and the other, James Muspratt, the founder of the Alkali Industry in this country. He was a pugnacious fellow even in his schoolboy days, and the Napoleonic wars drew him like a magnet, and he saw service not only in the Army in Spain, where he had the most thrilling adventures, but also in the Navy. Soon he was back again in Dublin engaged in the manufacture of prussiate in a small way, and in 1822 he came to Liverpool because of its more central position. The removal of the tax on salt in the next year gave him his opportunity, and he promptly installed a plant to work the Leblanc process.

It Sprang from the Napoleonic Wars

and the milestones along the road of progress are the wars of the century. This is an interesting fact. The war between the North and South of America was the first interruption to the steady progress which was being made in the industry. It fought its way through this handicap. Then came the Franco-German war, which was succeeded by a period of prosperity and of over-production, with the inevitable result. Prices fell to an unremunerative level and provided the stimulus for further research. Then came the ammonia soda process, introduced by Messrs. Brunner Mond & Company, and the struggle between the two processes compelled increased efficiency all round and the formation of the United Alkali Company as we know it to-day. Finally, there was the Great War, to which the industry contributed its full quota, and on the industry has been left the mark of that war also. Little wonder is there that such a goodly company of scientists and industrialists should be journeying down to Liverpool this week to mark the record of a century's work. Work which has placed that portion of British chemical industry on such a secure basis that no other country in the world has been able to assail it successfully.

FORTHCOMING EVENTS

Apr. 21. The Mining Institute of Scotland. The Forty-Sixth Annual Meeting, to be held in the Royal Technical College, George Street, Glasgow, at 3 p.m.

Apr. 23. The Institute of Brewing. Meeting at the Institute of Chemistry, 30, Russell Square, W.C. 1, at 8 p.m. Discussion on "Moisture in Malt."

Apr. 23. Royal Society of Arts, John Street, Adelphi, W.C. 2, at 8 p.m., Cantor Lecture. "Nitrates from Air" (Lecture 3), by E. Kilburn Scott, M.I.E.E.

Apr. 24. The Institution of Civil Engineers, Great George Street, Westminster, S.W. 1. Annual General Meeting.

Apr. 24. Royal Photographic Society of Great Britain. Meeting under the control of the Scientific and Technical Group, at 35, Russell Square, W.C. 1, at 7 p.m. "Photomicrography as Applied to the Iron-Carbon Alloys," by Capt. J. W. Bampfylde.

Apr. 25. Society of Chemical Industry, *Nottingham Section*, University College, Nottingham, at 8 p.m. (1) "The Action of Sodium Hyposulphite on Cupric Chloride in Aqueous Solution," by J. B. Firth, D.Sc., and J. Higson, B.Sc. (2) "The Sorption Activity of Carbon," by J. B. Firth. (3) "The Action of Potassium Carbonate on Lead Glass," by H. Droop Richmond, F.I.C. (4) "The Analysis of Lead Glasses," by J. M. Wilkie, B.Sc.

Apr. 25. Royal Society of Arts (Ordinary Meeting), at 4.30 p.m. Conference on "The Milk Question." (1) "The Arguments for Maintaining an Open Market for Fresh Milk," by Prof. R. S. Williams, B.Sc. (2) "Changes in the Digestibility and Nutritive Value of Milk induced by Heating," by Prof. J. C. Drummond, D.Sc. (3) "The Effect of Heat on some Physiological Principles in Milk," by S. S. Zilva, Ph.D. A Demonstration of some of the Chemical Changes in Milk on Heating to Various Temperatures will be given by Captain J. Golding, D.S.O., and Mrs. A. T. R. Mattick, M.Sc.

Apr. 25. The Royal Microscopical Society, *Industrial Applications Section*, at 7 p.m. (1) "The Manipulation of the Microscope in Industrial Laboratories," by J. E. Barnard, F.Inst.P. (2) "The Microscopical Examination of Coal in Relation to Fuel Economy and Efficiency," by Dr. M. C. Stopes.

Apr. 26. Society of Dyers and Colourists, *London Section*. At the Dyers' Hall, Dowgate Hill, E.C., at 7 p.m. "Fur Dyeing," by L. G. Lawrie.

Apr. 27. Society of Chemical Industry, *Liverpool Section*, Muspratt Lecture Theatre, the University, Liverpool, at 6 p.m. Annual General Meeting. "The Determination of Sulphur," by J. M. Taylor.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1923

In accordance with the provisions of By-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts School, Benet Street, Cambridge, on Thursday, June 21, 1923, at 11 a.m.

The programme of the proceedings will be issued shortly.

In accordance with the provisions of By-law 23 intimation is hereby given that the following members of Council retire from their respective offices at the forthcoming Annual General Meeting:—Dr. E. F. Armstrong, F.R.S., *President*; Mr. John Gray, Mr. D. Lloyd Howard, Mr. Emile Mond, and Mr. Edwin Thompson, *Vice-Presidents*; Dr. T. Howard Butler, Mr. F. H. Carr, Mr. W. H. Coleman, and Dr. R. T. Colgate, *Ordinary Members.*

Dr. E. F. Armstrong, F.R.S., has been nominated for re-election to the office of President under By-law 19; Dr. T. Howard Butler, Mr. F. H. Carr, Prof. G. G. Henderson, F.R.S., and Mr. Emile Mond, have been nominated Vice-Presidents under By-law 20.

Mr. E. V. Evans has been re-elected Hon. Treasurer, and Sir Wm. J. Pope, K.B.E., has been elected Hon. Foreign Secretary.

Members are requested to nominate, on or before May 15 next, fit and proper persons to fill the four vacancies among the Ordinary Members of Council. Forms for this purpose can be obtained from the General Secretary of the Society.

By-law 22.—An Ordinary Member of Council shall be nominated by five or more members upon Form B in the Schedule, a copy of which form shall be furnished by the General Secretary upon the written or verbal request of any member, but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form.

A nomination shall be declared invalid by the Council if:—

(*a*) The member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the By-laws.

(*b*) The nomination is not made on the authorised printed form, or substantially not in the manner directed thereon.

(*c*) The nomination form is signed by less than five members not disqualified or not ineligible to nominate as provided by the By-laws.

(*d*) The nomination form is not received before or upon the day appointed therefor.

(*e*) The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid shall receive notice thereof from the General Secretary, and shall not be submitted for election.

J. P. Longstaff,
General Secretary

MEETING OF COUNCIL

The monthly meeting of Council was held on April 13, 1923, the President (Dr. E. F. Armstrong, F.R.S.) in the Chair.

The President read a letter from Monsieur Deschiens, expressing his thanks for his reception in London and his pleasure in promoting good feeling between English and French chemists. He has presented to the Society a reproduction in colours of the portrait of Pasteur in the Sorbonne, which was accepted with thanks.

A proposal was received from the Council of the British Electrical and Allied Manufacturers' Association, which is responsible for the organisation of the World Power Conference to be held in June, 1924, at the British Empire Exhibition, that the Society should undertake the organisation of the Chemical Section of the Conference. The proposal was agreed to, and it was decided to ask the Chemical Engineering Group to undertake the arrangements.

The Council was invited to send a delegate to attend :—

(1) The celebration of the 75th anniversary of the Société des Ingénieurs Civils, to be held in May, 1923 ; and
(2) The 122nd anniversary of the Société d'Encouragement pour l'Industrie Nationale of France, in June, 1923.

It was agreed to ask Monsieur Paul Kestner to act as representative of the Society.

A letter of condolence was sent to Lady Dewar on the death of her husband, Sir James Dewar, F.R.S., a former President and Medallist of the Society.

The reports of the Hon. Treasurer and of various Committees of the Council were discussed, and 18 new members (home, 8 ; overseas, 10) were elected.

Dr. E. F. Armstrong, F.R.S., was nominated for re-election as President of the Society for the year 1923–24, and Dr. T. H. Butler, Mr. F. H. Carr, Prof. G. G. Henderson, F.R.S., and Mr. Emile Mond were nominated as Vice-Presidents. Mr. John Gray and Mr. D. Lloyd Howard, retiring Vice-Presidents, were specially thanked for their services to the Society during the years they have been on the Council. Mr. E. V. Evans was re-appointed Hon. Treasurer, and Sir W. J. Pope, K.B.E., F.R.S., was elected Hon. Foreign Secretary for 1923–24.

On the proposal of Sir W. J. Pope it was decided that the Society shall, following the practice of other scientific societies, give its Honorary Membership to a limited number (not more than 30) of distinguished foreign and colonial chemists.

It was agreed to enter into an arrangement with the Faraday Society (similar to that already made with the Chemical Society) by which papers for the Faraday Society may be presented at meetings of Local Sections of the Society of Chemical Industry.

Mr. F. H. Rogers and Mr. F. M. Potter were appointed representatives to serve on the Committee of the Institution of Civil Engineers concerned with the Tabulation of Results of Steam Engine and Boiler Trials.

It was agreed to ask Dr. W. R. Ormandy to act as the Society's representative on the sectional Committee of the British Engineering Standards Association set up to prepare Standards for petroleum products for engineering purposes.

NEWS FROM THE SECTIONS

LONDON SECTION

The meeting held at the Engineers' Club, Coventry Street, on April 9, was presided over by Mr. E. V. Evans, and two papers were read and discussed.

The first paper, entitled " The Cod-liver Oil Industry of Newfoundland," by Messrs. S. S. Zilva and J. C. Drummond, related to part of a detailed inquiry into the cod-liver oil industry, in order to elaborate a method for estimating the vitamin content of cod-liver oil, as it had been found that cod-liver oil was about 250 times as potent as an average sample of butter. It was necessary to investigate both the method and conditions of manufacture in Norway and in Newfoundland, these being the two chief centres of production. In Norway, the oil was not always pure cod-liver oil but was obtained from mixed catches of fish, whereas in Newfoundland, all the fish was cod, and the oil pure cod-liver oil. There were three main methods of producing cod-liver oil. The first was the process—now seldom used—in which the livers were allowed to rot and the oil rose to the surface ; the second consisted in steaming the liver in jacketted apparatus until the oil rose to the surface ; and in the third method, the one now mainly employed in Newfoundland, steam was blown into the liver to break up the tissues, the oil rising to the surface. The regulations for preparing oil by this method provided that the oil must be steamed until a scum was formed ; then decanted, filtered and stored in a tank for 24 hours, and then filtered again and casked. Samples of oil made by the jacketted process and the direct-steam process showed no difference in vitamin potency, so that the direct method was as good as the older method practised mainly by the Norwegians. The first fraction was decanted and used for medicinal purposes, the remaining second fraction being known in Newfoundland as common cod-liver oil, which was not used for medicinal purposes. It was found that the vitamin potency of this second fraction was almost as good as that of the first fraction and it seemed a pity that this fraction should only be used industrially because it would be quite good for medicinal use and for agricultural purposes, such as feeding cattle, etc. In the refining process the oil was chilled and the stearin settled out, an oil being obtained which did not go turbid when stored in a cool place. Oils obtained in 1919, 1920 and 1921 were tested and found not to vary in their vitamin potency as between each other. It had been proved that the fish did vary anatomically according to the place where they were caught, but investigation showed that the oil produced from the livers of these various fish did not differ in vitamin potency. The minimum dose of Newfoundland cod-liver oil necessary to promote growth in rats was from 1·2 to 1·6 mg. and there was a great uniformity of potency in the Newfoundland fish. With the well-known Lofoden cod-liver oil from Norway, the minimum dose was found to be 5 mg., and fish caught on the northern coasts of Norway showed a great variation in potency owing to the fact that the catches were often very mixed. There was little doubt that the high potency of the Newfoundland oil was characteristic of the fish of that part of the world and this fact, coupled with the very hygienic conditions under which the oil was produced, should place it very high on the market.

Capt. Gordon, Deputy High Commissioner for Newfoundland, who opened the discussion, said, at the present time Norway exported five times more cod-liver oil to this country than Newfoundland did, which was strange. Prof. J. C. Drummond said the idea seemed to be strongly held, especially by the medical profession, that only the oil coming from Norway was of any value. The authors had been much impressed with the fact that in removing the stearin a large amount of vitamin was also removed. Although the stearin was not as potent as the original oil, it was far more potent in most cases than the equivalent weight of butter and it seemed surprising that such a valuable product should be turned to technical use only. Dr. Zilva, in reply, said the use of open vessels in the direct-steam process in Newfoundland did not make any difference to the final product; he did not think there was much fear of losing much potency in refining. The amount of stearin extracted was from 2 to 3 per cent.

The second paper, bearing the title, "A Study of the Separation of the Gases formed in the *n*-Butyl Alcohol-Acetone Fermentation Process," was by E. W. Blair, B.Sc., T. S. Wheeler, B.Sc., and J. Reilly, M.A., D.Sc. The production of *n*-butyl alcohol and acetone by the fermentation of carbohydrate material is a comparatively new industry and, as yet, little attention has been given to the recovery of the gaseous products of the process. These products represent over 60 per cent. by weight of the products of the fermentation—*e.g.*, 100 lbs. of maize containing 65 per cent. of starch yield approximately 7 lbs. of acetone, 16 lbs. of *n*-butyl alcohol, 39 lbs. of carbon dioxide, 1 lb. of hydrogen and 1 lb. of fatty acids. The gas contains 60 per cent. by volume of carbon dioxide, and 40 per cent. of hydrogen with only traces of other gases; per 100 lbs. of maize it occupies 550 cubic feet at N.T.P.

In the plant employed, the fermentation-gas, measured through a meter, passed through a compressor whence it was delivered at a pressure of 11 atmospheres to the bottom of the first of two towers. The gas entered through a spray nozzle immediately underneath the bottom plate in the first tower, passed up through the packing, meeting the downward stream of water, finally leaving at the top with a composition 85 per cent. hydrogen, 15 per cent. carbon dioxide to be treated similarly in the second washer. The water was delivered at a pressure of some 50 lbs. above that of the gas into the top of the washers. On leaving at the bottom the water from each tower which was about equal in quantity flowed into a separate pressure breakdown where the gas evolved was discharged through relief valves set at the desired pressure. The water from both towers was measured and, passing through a spray, fell over louvres, during which it gave up the remaining dissolved gas. It then flowed back to the sump to be re-utilised. The gas from the second tower pressure breakdown, which has the approximate composition of the fermentation-gas, was passed to the crude-gas main to be rewashed. The plant washed some 300 cb. ft. (at 15°C and 1 at.) of 40 per cent. hydrogen-gas per hour; the time of washing in each tower was about 30 minutes. Only 1 cb. ft. of hydrogen was lost per 100 cb. ft. of gas treated.

Assuming that the water leaving the bottom of the tower is in equilibrium with the gas entering it, an equation can be obtained and curves drawn giving immediately the quantities of water required theoretically in each tower to wash the gas so that it may have given compositions leaving the first and second towers of the plant. Curves then can be deduced showing the quantities of hydrogen carried away by the water flowing from each tower. These curves have been found to apply in practice very accurately to the first tower in the plant where the hydrogen-gas (40 per cent. by volume) was washed so that it contained 85 per cent. of hydrogen by volume. The agreement between theory and practice was not good in the second tower; it is difficult to obtain equilibrium when the gas entering a tower contains more than 80 per cent. of hydrogen; this also applies when it is sought to wash fermentation-gas so that it may contain more than 90 per cent. of hydrogen. For example, with 40 per cent. hydrogen-gas entering a tower and 87 per cent. hydrogen-gas leaving, 9·84 cb. ft. of water was used per 100 cb. ft. (measured at ordinary pressures) of entering gas as against 9·60 cb. ft. on theory; when the exit gas was 95 per cent. hydrogen, 18 cb. ft. of water was actually used as against the theoretical 10 cb. ft.

Mr. E. V. Evans, in congratulating the authors on their paper, pointed out the great importance of cheap industrial hydrogen. Dr. Reilly observed that the plant was only an experimental unit and many of the questions raised had not been considered. There was plenty of gas, but he did not think the recovery of hydrogen could become a large-scale operation. Practically 25 per cent. of the hydrogen in the starch came off as hydrogen-gas, and in the tropical countries, with cheap supplies of starchy materials, recovery might be economically possible. The gas used was pure, containing no methane, and liquefaction would not pay. Mr. Wheeler, who read the paper, pointed out the difficulties in the way of using sodium or potassium bicarbonate to wash the gas. There was no need to de-gasify the water in the sump, which contained practically no gas, and it was doubtful whether the results in the second tower could be improved upon.

BIRMINGHAM AND MIDLAND SECTION

The annual meeting took place at University of Birmingham on April 10, Dr. E. B. Maxted presiding over a representative attendance of members.

The several offices were filled as follows:—Chairman, Dr. E. B. Maxted; vice-chairmen, Prof. G. T. Morgan and Mr. F. R. O'Shaughnessy; hon. sec. and treasurer, Mr. G. King; hon. auditor, Mr. C. Watson. The following were elected to the committee: Messrs. D. F. Twiss, A. W. Knapp, W. A. S. Calder, W. T. Collis, and A. E. Johnson.

Mr. King reported that nine meetings were held during the session, including a dinner, and the average attendance being 54. A large proportion of the papers communicated to the Section had been published or passed for publication in the *Journal*. Subject to the approval of the Council the Committee recommended the creation of an associate group of the Section, to embrace those under 24 years of age who desired to receive all local section communications and to attend meetings and other functions. A fee of 2s. 6d. would be charged to cover expenses. Such associates would, however, be ineligible for election to the committee and would not receive the *Journal* of the Society. They would not be considered associate members of the Society, but rather as associate members of the Birmingham Section. It was proposed to extend the scheme of co-operation with the Chemical Society to the Faraday Society. During the year the Society's library in London had been dispersed, and the Section had received a number of journals and some patent literature, weighing about two tons, which were stored in the University Library, where they might be consulted by members of the Society of Chemical Industry. In conclusion Mr. King asked for the more active co-operation of the members of the Society. The average attendance at meetings was less than 20 per cent. of the number of members. The committee therefore looked for and expected considerably more support from the main body of members. Mr. King added that the funds of the Society were devoted entirely to the futherance of chemical science. The *Journal* was not a commercial venture and it was the duty of all members as chemists to further the interests of the Society.

The Chairman observed that the past successful season had been due to a very large extent to the devoted work of the hon. secretary, Mr. G. King. He was to be congratulated upon the excellent series of meetings. A meeting had been held fortnightly since the opening of the new year. Alluding to the programme for next session he mentioned that the idea of holding a symposium for the consideration of "Colloids" was favoured, but whether that would be arranged would depend upon the support likely to be forthcoming. Suggestions in relation to papers were invited.

Subsequently Mr. F. R. O'Shaughnessy, A.R.C.Sc., read a paper on "Physics and Sewage Disposal."

The paper discussed the physical properties of the principal components of normal sewage (*i.e.*, of the water on the one hand and the usual polluting bodies on the other) as affecting the operations of preparatory treatment preliminary to disposal.

The effect of various methods of treatment on sewage were discussed, and it was shown that whereas the visible suspended solids in sewage were for the most part readily separated, the bulk of the colloidal solids were held very tenaciously by the sewage water. Colloidal solids were but partially thrown down by simple sedimentation. Chemical precipitation effected only partial removal, even when large amount of chemicals added, but, when in moderate amount, improved the liquor for the bacteria bed. Anærobic action removed colloids, but made the liquor very offensive; it was, however, the only means of precipitating colloidal solids.

The work of Mr. F. W. Stoddart indicated, that given a limpid sewage liquid, which had been freed from colloidal solids by appropriate means, the quantity of liquid which could be put through a suitable percolation bacterial bed might be immensely increased, even to 10 or 20 millions gallons per acre. The technique provided by Messrs. Ardern and Lockett in the activated sludge process had furnished the key to the solution of this problem, and the author suggested that a modified use of this technique, which he proposed to call the "flocculated sludge process," was the appropriate means of dealing with colloidal matter in solution.

The merits of the activated sludge process were :—Completion of sewage purification in one tank in one operation ; elimination of nuisance ; reduction of area, and production of valuable fertiliser. The objections were :—Existing works made useless ; sludge problem more complex ; economical recovery of sludge problematical ; extravagant, *i.e.*, prolonged, aeration, high oxygen demand by sludge, alteration of physical character of sludge, etc. ; slow rate of solution of oxygen in water the central physical fact here ; and in many cases protection required for aeration. The procedure in this process was arbitrary, its objective largely commercial, *i.e.*, to conserve manurial elements, and must stand or fall on financial merits.

In the flocculated sludge process three operations were involved :—(*a*) agitation of sewage and flocculated sludge with air for a time to bring about clarification of the sewage and partial purification of the liquor ; (*b*) separation of sludge from treated sewage and (*c*) re-aeration of separated sludge. This mode of procedure might be applied to the whole sewage (less grit, etc.), as in the activated sludge process or after any desired degree of preliminary sedimentation. Its advantages were :—The wide choice of procedure available, for the process could be incorporated with existing plant ; a greatly increased volume of liquid could be put on bacteria beds ; nuisance (odour and flies) could be eliminated, and the expensive aeration period reduced.

The theory of the flocculated sludge process was then discussed, and evidence given that the purification of sewage is effected by physical agents, which brought about flocculation of colloidal solids, and by biological agents which brought about oxidation of the dissolved impurities. In the activated sludge technique the real flocculating agent was the sludge, the condition of the sludge being much more important than its quantity ; with the procedure advocated in the flocculated sludge process very remarkable and rapid purification could be obtained with greatly reduced volume of sludge.

With sludge this change was conveniently effected by the inoffensive, intensive, anærobic digestion of the sludge as by the Imhoff Tank, or by the method of separate digestion, as at Birmingham (England) and Baltimore, U.S.A., and elsewhere. In conclusion, the author claimed that the cost of the latter method was relatively low.

MEETINGS OF OTHER SOCIETIES

FARADAY SOCIETY

The Meeting held on April 13 was devoted to a discussion on "Alloys Resistant to Corrosion," held jointly at Sheffield with the local section of the Institute of Metals and the Manchester Metallurgical Society.

In a paper on "Monel Metal," J. Arnott, A.I.C. pointed out that as the metal was primarily an engineering material with excellent physical properties and good resistance to corrosion its sphere of use was different from that of acid-resisting metals, such as the iron-silicon alloys which had to be used in certain cases, despite their poor mechanical properties. The author discussed the composition and physical properties of monel metal, and stated that it had a high resistance to impact, a low heat conductivity (about 7 per cent. of that of copper) and retained strength and ductility at high temperatures, retaining 85 per cent. of its normal strength at 750° F. The metal was little affected by exposure to fairly pure air, and it resisted sea water and steam perfectly. It was unsuitable for use with strong acids, but was not affected by alkalis and only slightly by solutions of most neutral salts at ordinary temperatures ; it, however, would resist dilute acid solutions.

"The Resistance to Corrosion of Stainless Steel and Iron" was discussed by J. H. G. Monypenny, who pointed out that, contrary to the general opinion, there was a wide range of stainless steels, in which the main variable was carbon, followed by silicon, manganese and nickel. The resistance to corrosion could also be modified by varying the heat treatment, and the greatest resistance was obtained by quenching from a temperature of 900° to 950° C. Tempering had little effect on the resistance to corrosion, although this was lessened by tempering between 500° and 600° C. When annealed between 700° and 750° C. the material was softer than when hardened and fully tempered, and less resistant to corrosion. When distorted by cold work stainless steel rusted comparatively readily, and this was why a polished surface on stainless steel was more resistant than a roughly machined surface, the effect being due to the absence of distorted skin. The resistance to staining increased with a decrease in the carbon content. The presence of silicon in notable amounts raised the critical ranges and diminished the air-hardening capacity, but a content of 1 per cent. silicon had little effect on corrodibility. Nickel present in amounts up to 2 per cent. had no appreciable effect on the resistance. In conclusion, the author discussed the resistance to various corroding agents, and concluded that the following were without action on stainless steel :—Tap, sea, river and well waters ; ammonia, alkalis and alkaline carbonates ; aqueous solutions of salts, with the exception of ammonium chloride; vinegar, fruit juices, atmospheric agents, and superheated steam. Hydrochloric and sulphuric acids attacked the material rapidly, but whereas fairly strong nitric acid was without effect, dilute nitric acid attacked stainless steel slowly.

Mr. U. R. Evans contributed a paper on "The Mechanism of the So-called 'Dry Corrosion' of Metals," in which he defined the types of corrosion as (*a*) "wet corrosion"; *i.e.*, when metal was completely immersed in water; (*b*) "wet and dry corrosion"; *i.e.*, when the metal was periodically wetted and allowed to dry; and (*c*) "apparently dry corrosion"; *i.e.*, where a metal protected from rain was exposed to air. The paper was devoted to the discussion of the "apparently dry corrosion," and described experiments with electrolytic copper, zinc, lead and iron foil, and brass, etc. All the specimens used were cleaned and roughened by rubbing with coarse emery cloth, and special attention was paid to the question of "reproducibility" when different samples of the same material, exposed under apparently similar conditions, did not behave in the same way. It was concluded that no corrosion occurred when these apparently dry metals were kept over sulphuric acid, and only slow superficial corrosion when kept over water. The rate of attack was greatly increased by the presence of volatile electrolytes in the air, sulphur dioxide being most dangerous to iron and nickel, ammonia to copper and its alloys, and hydrogen chloride to zinc and aluminium. Hydrogen sulphide and carbon dioxide somewhat increased the rate of rusting of iron, but produced only superficial changes on other metals. Corrosion of iron was not induced by the presence of ammonia. Corrosion by volatile electrolytes appeared to require the presence of some moisture, but proceeded in air which was distinctly unsaturated. Special phenomena occurred at the contact of dissimilar metals, apparent electro-chemical protection being observed in some cases. The phenomena could be explained by assuming that electro-chemical action occurred in the adherent film of moisture. Volatile electrolytes increased the conductivity of this film and thus accelerated corrosion. When hygroscopic corrosion-products were produced further moisture was absorbed; the thickness of the film increased; the metal, originally dry, soon began to shed liquid and became seriously corroded.

ANNALI DI CHIMICA APPLICATA

As the publication of this Italian periodical, initiated in 1913, was suspended in 1919, it is of interest to note that the Italian Association of Pure and Applied Chemistry and the Italian Society of Industrial Chemistry have decided to resume publication of the *Annali*, which will now appear once a fortnight.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on April 12, Sir Max Muspratt presiding.

Arrangements were made to obtain, for the benefit of all members, as complete a record as possible of the imports of chemicals into this country. Arrangements were also made to obtain statistics of the consumption of fuel, for power and other purposes, by the industry.

Details of the arrangements in connexion with the British Empire Exhibition, 1924, were reported to the Council. Rather more than 37,000 sq. ft. of space has been reserved for the Chemical Section. A largely attended meeting of exhibitors recommended that there should be a comprehensive scheme of lay-out and decoration covering the whole of the chemical section. Plans are being prepared and will be considered later.

A deputation consisting of Sir Gregory Foster, Sir Robert Robertson, Dr. Seton and Mr. W. MacNab from University College, London, was received in support of the appeal for funds in connexion with the establishment of a Chair of Chemical Engineering at the University College. It transpired that the object of the Chair was for the study of the Physics of Applied Chemistry, and, having regard to the importance of this subject, the Council agreed to commend the scheme to the members for their support.

Sir William Alexander reported that difficulties were being experienced in the dye industry in connexion with the price to be paid for British goods and that negotiations are still in hand with the colour users on the subject. It is interesting to note that the British dye industry is now able to supply 80 per cent. of the colours previously made by Germany.

PETROLEUM DEPOSITS IN ITALY

The existing petroleum wells in Italy are situated principally in Emilia, and yield an average of 6000 tons of crude oil per annum, a maximum of 7000 tons having been reached in 1916. According to the *European Commercial*, fresh deposits have been discovered near Ripi (province of Rome) at a depth of 470 metres, which yield about two tons of oil daily. As a result the Italian Ministry of Agriculture has appointed a committee of geologists to direct the systematic examination of the whole country for further deposits. The committee reports that preliminary surveys in Emilia, Lazio, Campania, Apulia, Abruzzo, Basilicata, Calabria and Sicily have revealed sufficient indications of hydrocarbons to justify the expense of preliminary borings, and it is anticipated that important results will be obtained.

CORRESPONDENCE

THE TITLE "CHEMIST"

Sir,—The correspondence on this matter is indicative of a desire to do the right and proper thing for all concerned, but no practical suggestion has been put forward for discussion. On committee work it is often useful to have a suggestion, which is bad in principle, so that it may be "flogged to death" and from the carcase some useful bones are often picked.

If we look back in history we find the word "clerk" had a very restricted use, to-day it is the appellation of millions of workers and yet the correct designation of some thousands of clergymen to-day is "clerk in holy orders."

There must have been a time when the word clerk ceased to have its original meaning and to-day the title "chemist" has certainly been restricted for the use of certain trained people—men and women—by an "Act of Parliament," which could never have anticipated the advances to be made by chemical science. The Pharmaceutical Society has not been backward in the use of the title "Pharmacist" as describing the qualified persons who may keep open shop in such a way as complies with the Pharmacy, Poisons and other Acts of Parliament, but the official title of a shop-keeping pharmacist remains at "Chemist and Druggist." The word is in keeping with the French "pharmacien" and the German "pharmazent," and is descriptive to the rising generation. But supposing that the Pharmaceutical Society were willing to ask Parliamentary sanction for altering the title "Chemist and Druggist" to "Pharmacist" the difficulty remains; who is to be called a "Chemist"? We are left with a word similar to the above cited "clerk," which may belong rightfully to all kinds of chemists, and who is to control them all and protect the public from the unskilled, or the skilled scientist from unscrupulous advertisers?

We need a new word and it should not be beyond the ingenuity of man to coin a euphonious one. If the pharmacists wanted a new name the word Galenist might be acceptable to the disciples of Galen. To carry the analogy into the realm of modern chemistry and adopt a parent from one of our deceased great chemists gives rise to such words as Davyist, Crookesist, Ramsayist, Listerist; which would be meaningless for the next fifty years and we are almost forced back on the root "Chem," which is again in accord with the French and German. So also would be the word Alchemist and there seems no reason whatever why that name should not be rejuvenated and attached exclusively to such chemists as are properly trained and qualified to carry on skilled chemical work in all its branches. There are many good titles beginning with the initial letter "A" and, although it may sound too exclusive to most of us, yet not a few chemists would be pleased with anything less than *Alph-Ega* for their descriptive cognomen. How would dignity sit at the feet of an Alphegist or the Journal of the Society of Alphegists tower above the present effort in journalese?—I am, Sir, etc.,

C. Edward Sage

10, London Street, E.C.

ARTIFICIAL FATS AND FATTY ACIDS

Sir,—After reading your correspondent's excellent article on "Artificial Fats and Fatty Acids," a subject to which I have devoted some little attention, I am stimulated, with your permission, to make the following observations:

It may be contended that the attempts to compete with nature in the production of such a complex substance as even the simplest natural fat is at present little more than wasted effort, and that it were better and economically sounder to devote attention to the stimulation of nature to greater production. There are many arguments which may be advanced in support of this contention, the most cogent being that no-one yet knows enough concerning the total ingredients of the natural fats to render their reproduction from synthetic substances possible. The natural fat, with its complex organisation of mixed glycerides, phytosterols, chromogenetic substances, vitamins and other undiscovered or unidentified minor ingredients, is in no danger of being supplanted by rival artificial productions for many years to come.

This is, however, fully realised by the technical and industrial research chemists who are interested in the question. In fact, industrial research in this connexion is concentrated not so much on the artificial production of a fat identical with natural fat, but on the manufacture of products which shall prove suitable as a substitute for natural fat in some particular industry. The chemical constitution of the substance is not of first importance so long as the substitute can be produced more economically than the natural fat and is not detrimental to the quality of the article to be manufactured from it.

Viewed from this standpoint the developments which have been made in the technical production of fatty substances during the last few years in this and other countries are of practical significance and offer considerable promise of successful application.—I am, Sir, etc.,

A. N. Salway

BAYBERRY OIL

Sir,—With reference to the correspondence which has recently appeared in connexion with the above oil, Lewkowitch (Vol. II., sixth ed., p. 509) gives considerable information concerning bayberry or laurel oil (*Laurus nobilis* L.), whilst Jumelle (Les Huiles Végétales, 1921,

p. 166) states the following data:—S.g., at 15° C., 0·995, m.p., 40°—48° C.; solidifying point, 45°—39° C.; acid value, 3—4·4; saponification value, 205—217; iodine value, 2—3·9; Reichert-Meissel value, 0·5; solidifying point of fatty acid, 46° C. He says that the preponderating fatty acid is palmitic, with a little oleic acid and a small quantity of lauric acid. The iodine value is much lower than that given by Lewkowitch (*loc. cit.*), but is more in accordance with that published by Mr. C. J. Gundel in your last issue (p. 373).—I am, Sir, etc.,

London, S.E. 1. A. Harvey
April 13, 1923.

PERSONALIA

Sir J. J. Thompson has been awarded the John Scott Medal, and an accompanying purse of $1000, by the American Philosophical Society, and the Franklin Medal by the Franklin Institute. The John Scott Medal and a money prize have also been awarded to Dr. F. W. Aston for his work on Isotopes, and to Dr. Eijkman of the Utrecht University for research in medical science.

Prof. G. Louis will retire from the chair of mining and surveying and the William Cochrane lectureship in Metallurgy at Armstrong College on September 30, on reaching the age for retirement. Prof. G. Pool, of the University of Leeds, has been appointed professor of mining and Dr. J. A. Smythe, at present senior lecturer in chemistry, will take over the William Cochrane lectureship in metallurgy.

Mr. T. J. Pentecost, F.C.S., has been elected to the presidency of the Society of Dyers and Colourists.

The Bessemer Medal of the Iron and Steel Institute will be presented to Dr. W. H. Maw, at the annual meeting of May 10.

The Willard Gibbs medal of the Chicago Section of the American Chemical Society has been awarded to Prof. J. Stieglitz for his researches in organic chemistry.

Prof. Brogger, of Christiania, has been elected a foreign member of the Académie des Sciences.

It is announced in *Nature* that the tricentenary of the birth of Blaise Pascal occurs on June 19, and preparations have been made to hold official celebrations in France on July 8 and 9.

* * *

The death is announced from Germany of Prof. G. Köhler, aged 84, Director of the Clausthal Mining Academy and author of important treatises on mining.

From France the death is announced of Monsieur Edouard Dreux, managing director of the Longwy Steel Works, and well-known in the French metallurgical industry.

NEWS AND NOTES

CANADA

The Iron and Steel Industry in 1920

A report issued by the Dominion Bureau of Statistics (Mining, Metallurgical and Chemical Branch) states that the cost of materials used by the Canadian iron and steel industry in 1920 was $321,298,396, and the value of the products $640,233,785, $318,935,389 having been added to the value by manufacture in the 1475 establishments engaged in the industry. The earnings of the 102,661 wage-earners totalled $132,885,132, and the total capital invested in the industry amounted to $642,904,322. A large range of commodities was produced, the chief being 1,090,396 tons of pig iron and 1,166,691 tons of ingots, 191,283 tons of steel bars, 216,172 tons of wire rods, and 737,729 tons of blooms, billets, etc. By far the largest proportion of the industry is located in Ontario, 65·9 per cent. of the total capital of the industry being invested in that province, followed by Quebec with 20·5 per cent. of the entire capital and Nova Scotia with 5·3 per cent.

UNITED STATES

The Technology of Slate

The United States Bureau of Mines has published as Bulletin 218 (price 20 cents.) a useful monograph on the "Technology of Slate" by Oliver Bowles. Starting with an account of the properties of slate and features of the deposits, the author goes on to discuss faults, testing, uses, quarrying and manufacture. A most interesting section is contributed under the heading, "The Problem of Waste," a most important feature of the industry, as the waste averages in most regions 70 to 90 per cent. of the gross output, and even as much as 50 or 60 per cent. under favourable conditions. Waste is due to imperfections in the material itself, and to losses in quarrying, etc. After considering methods to reduce waste in manufacture, an interesting account is given of the progress made in utilising slate waste, of which veritable mountains are available. Claims have been made that waste slate can be used in manufacturing brick, pottery, roofing tiles, glass, paint, distempers, putty, metal polish, abrasive soap, insulators, rubber goods, asphalt, Portland cement, and even toilet powders. Experience shows that the material can be used advantageously as a filler in rubber goods, oilcloths, floor coverings, etc., as well as for plastic roofing and flooring products. For some products, a much finer grain slate "flour" is required, and when a uniform, reliable product, 95 per cent. of which will pass a 300-mesh screen, is available, a considerably wider use could be found in the manufacture of products requiring extremely finely grained fillers. The various uses outlined above are discussed in detail in the Bulletin, much information having been derived from work done in Wales.

GERMANY

Aluminium Industry

The aluminium industry is the only metallurgical industry developed in Germany during the war which has not since suffered severe setbacks, and the metal continues to find fresh applications. In electrical installations aluminium is being used instead of copper for cables ; this development is aided by the fact that the metal is not needed in such a high state of purity as copper, whilst its low specific gravity and the good price it commands as scrap-metal are also favourable factors. Aluminium is also taking the place of copper and brass in the manufacture of scientific apparatus. In this case it possesses the advantage that no tinning or nickel-plating is needed to prevent the corrosion which copper and brass may suffer. The brewing industry has adopted aluminium as a material for barrels and pans. Many machine parts are now made of the metal, such as pistons and connecting rods in internal-combustion engines. Aluminium has also a firmly established position as a material for household utensils, though the problem of cleaning such utensils is still a matter of difficulty. A great advantage of the metal is its cheapness since an aluminium article costs only half as much as a similar one made of brass.

In conjunction with other branches of industry the first German aluminium exhibition is to be held next summer at Cologne. It is intended as propaganda for the new aluminium industry, to open up new markets and make known the possibilities of the metal. A special film is being prepared, " Aluminium, the metal of the future," which will be shown nightly, accompanied by an explanatory lecture.

Yeast as a Food

We have received a pamphlet of 16 pages, entitled *Der Mensch und die Hefe*, by Prof. W. Küster, of Stuttgart. It is the first number of a new series of Biochemische Tagesfragen, or bio-chemical problems of to-day, and deals with comparative biochemistry and the bases of a rational method of nutrition, for the benefit of those " who do not understand the a, b, c of chemistry." The author does not equal Faraday in his powers of popular exposition, and the chemistry of the human body, and even of yeast, is much more complex than that of a candle ; hence we may doubt whether the pamphlet will convey to a general public all that it is intended to do. In part it is a plea for the more extensive use of yeast as a food, but its most interesting feature is probably that, even in the present troubled times, there should be in Germany a lay public sufficiently large and sufficiently interested in science to make the new series worth printing. Indeed, science still commands in Germany a greater respect than elsewhere ; interest in science is still more widely diffused there than in any other country.

GENERAL

Research on Portland Cement

The British Portland Cement Research Association has published a pamphlet (No. 1, pp. 35) on the setting of Portland Cement compiled by W. L. Gadd. It is stated that, in the opinion of the Council of the Association the investigation of methods for the regulation of setting time and the causes of changes in the setting time of portland cement has reached such a stage as to justify the presentation of a summary of the results. The Council hopes, at some further time, to return to the investigation with a view to discovering improvements in methods of regulating setting and means of preventing changes in the setting time. Work is now proceeding upon the action of colloids and fatty acids on the setting and other properties of cement. A summary of the chief points raised in this pamphlet will appear in the Abstract section of this *Journal* at an early date.

Research in Paper-Making

The Technical Section of the Paper Makers' Association of Great Britain and Ireland have associated themselves with a scheme of research to be carried on in the laboratories of the University College, Gower Street, London. The fields of research include investigation of the phenomena of the beater and beating process, both physico-chemical and physico-mechanical ; beating of selected standard celluloses, cotton, wood, esparto ; effect of the ordinary saline impurities incidental to paper mill treatment. Special investigation will be made into the " alum effect " and in general into the effects resulting from interaction of celluloses and sulphate of alumina. The research work will also bear on methods of diagnosing degree of hydration and the effect of special admixtures, electrolytes and colloids. A small committee consisting of Prof. F. G. Donnan, F.R.S., Mr. C. F. Cross, F.R.S., Mr. Arthur Baker and Captain W. E. Nuttall, will control the scheme of research, and the experimental work will be carried out by Mr. J. W. Rowe, B.A., Post Graduate Research Scholar, in the Laboratories of the University College, London, under the immediate direction of Prof. F. G. Donnan.

The World's Output of Olive Oil in 1922

Figures published by the International Institute of Agriculture, Rome, indicate a total world's production of olive oil of 15,053 thousand centals in 1922, no less than 14,197·2 thousand centals having been produced in Europe and the remainder in Africa. This total represents over 90 per cent. of the world's production of olive oil and compares with a production of 11,382·7 thousand centals in 1921 and an average output during the period 1909-1913 estimated at 11,565·7 centals.

REVIEWS

THE VAT-DYE INDUSTRY IN GREAT BRITAIN

Synthetic Colouring Matters: Vat Colours. *By* Prof. J. F. Thorpe, F.R.S., *and* C. K. Ingold, D.Sc. *Monographs on Industrial Chemistry, edited by* Sir E. Thorpe. *Pp.* *xv*+491. *London: Longmans, Green and Co.,* 1922. *Price* 16*s*.

This treatise, one of the well-known series of monographs edited by Sir Edward Thorpe, will appeal to two classes of readers, those engaged in the production or use of vat colours and those who wish to gain a general knowledge of this interesting but very intricate group of synthetic colouring matters.

The latter class will certainly appreciate the completeness with which the authors have dealt with the historical introduction to the subject. Included in the category of vat colours are two of the dyes of antiquity, Tyrian purple and indigo, and on these topics the authors have made the most of their opportunities. The chapters on "the purple of the ancients" and "natural indigo" contain in a concise but very readable form an epitome of the ancient and modern literatures of these pigments. The ceremonial use of purple in ancient civilisations, the lapse of its manufacture during the dark ages, and the rediscovery and identification of the colour in modern times constitute one of the most enthralling romances in the history of science. The oft told tale of indigo possesses a similar fascination.

Modern vat dyes are products of the twentieth century, for their discovery synchronises with the beginning of this epoch. It was not until 1901 that indanthrene and flavanthrene were placed on the market by the Badische Anilin and Soda Fabrik. The same year saw the introduction of tetrachloroindigo, and thioindigo came later in 1906. Since these recent dates the scientific and industrial developments in this field of organic synthesis have been enormous, so that in place of one blue vat dye, indigo—the purple having long since become obsolete—dyers now have the choice of scores of these colouring matters giving every imaginable hue, and often excelling the prototype in brilliancy and durability.

The chemical constitutions of these new colouring matters are extremely complicated, and the authors are to be congratulated on the way in which they have evolved order out of chaos in the matter of classification and terminology. Following on a chapter devoted to synthetic indigo are sections dealing successively with its substitution products and homologues, and with its analogues derived from similar and dissimilar component nuclei. Over 200 pages are taken up with vat dyes from anthraquinone, special attention being paid to the chemistry of the first two industrialised products, indanthrene and flavanthrene.

The value of the work to chemical students is enhanced by two chapters giving experimental details for preparing certain representative vat colours and their intermediates. In spite of the highly technical and complicated character of the text, there are remarkably few errors and these are generally of a trivial character.

This monograph on vat colours appears at a psychological moment in the history of the manufacture of these dyes in Great Britain.

Until 1914, synthetic indigo and other modern vat dyes were a German monopoly restrained only to a limited extent by Swiss competition. No attempt had up to that time been made to produce vat colours in this country and on the outbreak of war there was an acute shortage of these indispensable dyes in England, and among the Allies generally. In 1915 the Sundour Fabrics Company, under the inspiration of Mr. James Morton, attempted the desperate expedient of manufacturing these complicated products without any previous knowledge of the art, and although everything essential had to be improvised, the enterprise succeeded. Other firms followed, and at present there are at least two actual British makers of vat colours, and two or three others who are potential producers. In most cases the quality leaves nothing to be desired; it is up to German standard, but the inexorable question of cost arises. Partly owing to the extreme youth and inexperience of the British vat-dye industry, which has been in existence for not more than seven years, and partly and to a larger extent because of the disparity of the exchanges, German products can be sold at prices with which at present British makers cannot compete. In this country the raw materials alone represent approximately three times the pre-war price of the German vat dyes. Obviously the finished product must, in existing circumstances, be relatively expensive. The other horn of the dilemma is represented by the position of the British dye users, who are faced with the competition in neutral and colonial markets of dyed and printed fabrics produced by foreign dyers and printers having access to cheap German dyes. Some solution of this knotty problem must be found without delay, otherwise our newly won independence of German dyewares will disappear, and with it will go one of our most highly skilled chemical industries and our hopes for a renaissance of applied organic chemistry within the British Empire.

That our anxieties in this direction should not, however, blind us to similar crises existing in other skilled industries is a lesson to be drawn from the significant circumstance that this monograph now under review, the first English treatise of its kind, is printed in Saxony.

G. T. Morgan

Oxidations and Reductions in the Animal Body. *By* H. D. Dakin, D.Sc., F.R.S. Monographs on Biochemistry, *edited by* Dr. R. H. A. Plimmer *and* Prof. F. G. Hopkins. *Second edition. Pp. ix*+176. *London: Longmans Green and Co.*, 1922. *Price* 6*s.*

The series of *Monographs on Biochemistry*, edited by Dr. R. H. A. Plimmer and Prof. F. G. Hopkins, has proved an undoubted success, and has been imitated in this country, as well as in Germany and the United States. The book under review is the second edition of a monograph on some aspects of intermediary metabolism.

Since Lavoisier, we know that the food we eat is burnt, as if in a fire, to carbon dioxide and water. But what are the intermediate steps? It is only during the last few decades that we have obtained something like an answer to this question, and Dr. Dakin has taken a large share in the unravelling of the sequence of reactions which go on in the body. His work affords one of the best examples of the successful application of organic chemistry to the elucidation of vital processes; it is one of the most interesting chapters in "dynamic" biochemistry; it is real chemistry, yet intimately associated with the living cell.

Let us take a concrete example. How is our breakfast bacon ultimately transformed into carbon dioxide and water? Before absorption into the blood stream, the fat is hydrolysed, but by what stages are the long carbon chains of the fatty acids slowly burnt? Readers of Dr. Dakin's book will learn that, according to Knoop's theory of β-oxidation, proved experimentally by Embden and others, stearic acid is successively transformed to myristic, lauric, decoic, octoic acid, etc. Each time two carbon atoms are removed. It is not a mere accident that milk contains only fatty acids with an even number of carbon atoms. Knoop's theory was at first attacked, because it was contrary to the experience of the organic chemist. Dr. Dakin himself, however, discovered in hydrogen peroxide a reagent which attacks the β-carbon atom *in vitro*. He even quotes an analogy from technical chemistry; Fischer and Schneider and others in Germany have recently shown that paraffin wax may be oxidised by air at 140-170° C. to a series of fatty acids in which the successive members differ from each other by two carbon atoms.

In another chapter of the monograph we learn how the various amino-acids of protein are oxidised. The chapter on the oxidation of carbohydrates has, most opportunely, required re-writing, and is of special interest owing to the recent discovery of insulin as a remedial agent in diabetes and because of the suggestion that the sugar of normal blood may be γ-glucose. Pathological conditions, as in diabetes, in which sugar cannot be burnt, and the oxidation of the long carbon chain stops short at aceto-acetic acid, or as in alkaptonuria, in which the benzene nucleus of tyrosine and phenylalanine resists oxidation, give valuable information as to the nature of the oxidative processes in the body.

There is also much important new matter in the introduction and in the section on the nature of oxidising and reducing agents, since these deal (rather succinctly) with Wieland's theory of dehydrogenation, Hopkins's work on glutathione, and the researches of Meyerhof and of Thunberg.

The second edition has been well printed in Germany, and except for the paper, the get-up is quite as good as that of the pre-war edition. In particular there are but few misprints. The most likely place to find these is in the extensive bibliography, which forms a valuable feature of this, as of other monographs of the series. Here a few names have been misspelt: Mummery, Röhmann and Traube (p. 146); Balcar (p. 163); Knoop (p. 164); Bezzola (p. 167); Thannhauser (p. 169).

George Barger

Vanille, Vanilline, Vanille-Extracten. *By* Dr. W. L. Utermark. *Koloniaal Instituut te Amsterdam, Mededeeling No. XVII. Afdeeling Handelsmuseum No.* 3. *Pp.* 116. *Amsterdam: Koloniaal Instituut*, 1922. *Price* 2·50 *florins.*

This little brochure, published by the Amsterdam Colonial Institute, forms a useful and comprehensive compilation on the natural and artificial vanilla flavours.

A short chapter on the botany of the vanilla plant and on its cultivation includes some excellent photographs; there are also some interesting illustrations of the process of artificial fertilisation, first introduced by Charles Morren in 1836, and developed by Albius in 1841, and now practically universally used.

The chapter on the chemistry of vanillin and its artificial production is fairly comprehensive, without too much detail, but not nearly so wide in its scope as a fairly recent series of articles on the subject which appeared in *La Parfumerie Moderne.*

The few pages on vanilla extracts are good so far as they go, but they are necessarily ambiguous and doubtful on account of the different methods of dealing with them in various countries. For example, attempts to standardise, with much emphasis on the so-called "lead number," have been made by foremost officials and unofficial chemists in the United States, whereas nothing of the kind has been done, for example, in this country.

The summary of methods of determination of vanillin in vanilla is very good and very accurate. This little work is to be commended as a useful summary on the subject, and one which all interested in the vanilla flavour would do well to consult.

Ernest J. Parry

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Salt Duty in India

In reply to Mr. Trevelyan, Earl Winterton said that the Indian Finance Bill containing a clause raising the rate of salt duty from Rs. 1·4 to 2·8 per maund which was rejected by the Legislative Assembly was certified by the Governor-General to be essential and accordingly became an Act of the Indian legislature. The Act was now operative.—(Apr. 9.)

British Industries Fair

Lieut.-Col. Buckley, answering Mr. Gilbert, said that the cost of the British Industries Fair recently organised by the Department of Overseas Trade at the White City was roughly £36,000, which was fully covered by revenue. The Birmingham section of the Fair was not organised by the Department, and did not involve expenditure out of public funds. The amount of orders received could not be estimated, but it was understood that satisfactory business was done this year.—(Apr. 9.)

Importation of Dyestuffs

Viscount Wolmer informed Mr. H. Simpson that the Central Importing Agency was set up by Messrs. Fairclough, Dodd and Jones to act as agents of the Board of Trade for the distribution of German reparation dyes.

Answering Mr. Pringle, Sir P. Lloyd Graeme said that the original arrangement made with the Agency did not provide adequate remuneration for the services performed by the Agency and the subsequent increase of the rate of remuneration had no connexion with the fact that the Agency had incurred bad debts. It was estimated that the amount to be credited to the German Reparation Account to date in respect of dyes and dyestuffs was, approximately, £950,000 and the amount realised from sales, approximately, £1,043,000. The realisable value of stocks on hand was estimated at £110,000 and the amount of profit realised to March 31, 1922, was £137,000.—(Apr. 9, 10.)

Dangerous Drugs and Poisons (Amendment) Bill

This Bill passed the third reading on April 9. The object of the Bill is to amend the Dangerous Drugs Act, 1920, and Section 17 of the Pharmacy Act, 1868, with a view to establishing closer control over the sale, distribution, and utilisation of dangerous drugs. Medical practitioners are relieved of the necessity of signing when purchasing poison for the purposes of their profession, and clauses are inserted in conformity with the provisions of the International Opium Convention, 1912.

Chemical Treatment of Imported Meat

In answer to Mr. H. Simpson, Mr. Chamberlain said that so far as he was aware, no meat treated with formaldehyde or sulphur dioxide had recently been imported into this country.—(Apr. 11.)

Imports and Consumption of Potash

Viscount Wolmer, in a written answer to Dr. Chapple, gave the quantities of potassium salts largely, but not wholly, used for manurial purposes and imported into the United Kingdom from Germany during 1920, 1921 and 1922 as follows :—

	1920	1921	1922
		Cwts.	
Potassium chloride ..	119,447	83,612	348,201
Kainite and other potash fertiliser salts	230,077	607,648	1,989,618
Potassium sulphate ..	103,450	47,870	156,473

Kainite, with 12½ per cent. potash, was sold at an average price of 103s. per ton in 1921 and 55s. per ton in 1922 for 2-ton lots, free on rail. In 1912 it was estimated that 80,000 tons of potash was used in agriculture and in 1922 the imports into Great Britain and Ireland of potassium compounds (excluding potassium nitrate) were 200,357 tons of an average value of 93s. per ton, but how much of this was used for manurial purposes was not known.—(Apr. 12.)

LEGAL INTELLIGENCE

Absortion of Arsenic by Potassium Carbonate from Glass Bottle. Birmingham Corporation *v* Boots' Cash Chemists (Western), Ltd.

On April 13 a case was heard by the Birmingham magistrates in which Boots Cash Chemists (Western), Ltd., of Nottingham, were summoned for selling at 275, Coventry Road, Small Heath, potassium carbonate which was not of the quality demanded, as it contained 80 parts of lead per million and about 10 parts of arsenic per million.

Mr. Liverseege, the city analyst, said that the article was impure commercial salt of tartar instead of pure potassium carbonate, and contained 16 times the lead and 5 times the arsenic allowed in the British Pharmacopœia. The price of the pure drug was charged for the impure article, so that the sale prejudiced the purchaser. He did not think it probable that the arsenic and lead were absorbed from the bottle, because the substance was dried.

Mr. H. Droop Richmond, F.I.C., Chief Analyst to Boots Pure Drug Co., said that as he found the product really contained lead and arsenic, he analysed the glass of the bottle containing it and found that potassium carbonate, which was hygroscopic, had extracted lead and arsenic from the glass. On putting potassium carbonate in a similar bottle, less than 5 parts per million of arsenic had increased to 15 parts per million in a fortnight.

The magistrates dismissed the case, and the chairman said that they believed Mr. Droop Richmond's discovery would be historical.

COMPANY NEWS

SALT UNION, LTD.

Mr. G. H. Cox, who presided over the annual meeting held in Liverpool on March 27, reviewed the state of trade during the past year, and said there was considerable improvement, due to the absence of any interruption to production and delivery, and to reduced cost of production. During the past year economies of production and administration had been effected by concentration of work at the most favourable centres, and the results had proved very beneficial. The export trade was satisfactory, exports to India having increased despite competition from German and solar salt. Shipments to Rangoon were maintained, and those to Japan, which had been entirely arrested, had now been resumed, and West African trade was also growing. The research department had solved several important problems, and had made it possible to establish a chemical industry to utilise a waste product, a plant having now been erected to produce magnesium carbonate on a commercial scale. A new purifier and preservative which was a by-product had also been placed on the market. The immediate outlook for the salt trade was fairly satisfactory, but further improvement was hindered by heavy taxation and costs. The home trade had had to meet heavy foreign competition, and prices in some cases declined to the level of costs. The net surplus of £182,228 was allocated as follows: Preference dividend, £70,000; ordinary dividend, £80,000; staff superannuation fund, £10,000; carry forward, £20,228. During the past year the B debenture issue had been cancelled in exchange for first debenture stock.

BRITISH PORTLAND CEMENT MANUFACTURERS, LTD.

The annual meeting was held on March 28, under the presidency of the Hon. F. C. Stanley, who stated that the associated company had purchased the works and other assets of the Kent Portland Cement Co., Ltd., and had guaranteed the issue by that company of £6,600,000 of Kent 6½ per cent. debenture stock. The dividend was maintained at 10 per cent., but trading conditions were very difficult; the demand was very small, and the turnover was less than in the previous year. It was to be regretted that certain public authorities had placed contracts for cement, etc. with continental manufacturers assisted by depreciated currencies. The immediate outlook was not as promising as could be wished, for but little reduction in the cost of manufacture could be expected. The reductions already made in the selling prices would exceed any possible saving in manufacturing costs. Nothing was being neglected to increase the use of cement, and the use of concrete in road construction was being vigorously advocated.

REPORT

Report on the Financial and Economic Conditions of the Argentine Republic, September, 1922. *By* H. O. Chalkley, *H.M. Commercial Secretary, Buenos Aires. Pp.* 52. *Department of Overseas Trade. H.M. Stationery Office,* 1922. *Price* 1s. 6d.

Trade in Argentina was stagnant during 1922, and, though the outlook is generally considered to be hopeful, the individual trader is not yet able to feel any optimism. Europe is too poor to buy Argentine products and in some cases values have fallen till they hardly cover the cost of production. The sugar market is somewhat depressed since unnecessarily large imports were made in 1921 to augment the home production of 194,000 tons; an output of 200,000 tons is estimated for 1922. Trade in hides exceeded expectations in 1922, the exports for the first seven months being almost equal to the total for 1921. Cotton was produced in 1921 to the extent of 18,000 t., part of which was exported. The dairy industry continues to flourish, though early in 1922 it passed through a critical period; 6568 t. of casein was exported in the first half of 1922. Petroleum continues to be the chief mineral product. During the first half of 1922 the State fields, far and away the most important, produced 1,013,000 barrels, compared with 1,730,000 during the whole of 1921. A still higher output will probably be attempted under the new Government. Other mining enterprises remain unimportant; the non-metalliferous minerals, such as borates, salt, gypsum, limestone, and mica are the most worked. The position of manufacturing industries has changed very little since 1921 (*cf.* J., 1922, 106 R).

Exports in 1921 were estimated at £132,900,000 (£1=5·04 gold pesos); details are not given of the countries of destination, but the items include:—Quebracho, logs, 30,857 t., extract, 120,100 t.; hides, 4,368,073; skins, 45,467 bales; tallow, 19,375 t. Imports were valued at about £155,000,000. The latest analysis of imports is for 1920 when iron and steel was imported to the value of £27,418,000; coal, cement, sand, bricks, etc., £15,838,000; glass, porcelain, china, £2,602,000; chemicals and drugs, £9,313,000; oils, fats, petroleum, petroleum products, £10,229,000; paints, varnish, dyes, ink, £1,521,000; tinplate, copper, lead, zinc, £1,095,000.

The volume of British exports to Argentina decreased from £42,921,254 in 1920 to £27,622,024 in 1921 and in the first six months of 1922 to £10,993,379. The principal articles imported from the United Kingdom are coal, iron and steel goods, and textiles. Competition in Argentine markets is not now restricted to the United States and the United Kingdom; Germany, Belgium, Spain, France, and Italy have also entered the lists, although the United Kingdom appears to have the best chances of increasing its trade.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for April* 5 *and* 12)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Albania	Chinaware	423
,,	Iron, steel, cement	425
,,	Sugar	10313,F.E./CC/2
,,	Paint and varnish	459
Algeria	Sugar	489
Argentina	Tin, tinplate, linseed oil, soap, perfumery	492
,,	Shellac, gold leaf, bronze and aluminium powders	493
Australia	Aluminium ware	*
British India	Portland cement (tender for)	†
Canada	Salt	418
Czechoslovakia	Dyes	427
Denmark	Edible animal oils and fats	428
Egypt	Leather (tender for)	**
,,	Linseed oil	488
Italy (Fiume)	Hides, kips, etc.	430
Netherlands	Pottery, china, glass	432
,,	Non-ferrous metals, chemicals	434
Netherland E. Indies	Photographic plates, films, printing paper and chemicals	442
Norway	Asbestos goods, tar products, paper and pulp supplies	477
Panama	Leather goods, paints	494
,,	Perfumery	495
Poland	Tin, antimony regulus, aluminium, chemicals, drugs	478
Peru	Earthenware	496
Siam	Paint (tender for)	10059/F.E.
South Africa	Varnish and enamel (tender for)	10872/E.D./C.C./2
Spain	Edible oil	481
Switzerland	Chemicals, pharmaceuticals, resins, oils	485
United States	Iron and steel	18677/10/F.W./E.C./2

TARIFF CUSTOMS EXCISE

Australia.—Dumping duties have been applied to German glassware and Norwegian calcium carbide.

Canada.—" Dumping " duty is not to be applied to goods from countries with depreciated currencies, provided that the selling price in Canada is not less than the fair market value in the country of origin. Previously such goods were appraised according to their value when produced and sold in the United Kingdom or other European country whose currency has not substantially depreciated. Artificial silk for manufacturing purposes may be imported duty-free.

Far Eastern Republic.—Importation of all goods is subject to licence ; articles, the importation of which is prohibited, include various metallurgical, leather, mineral, chemical, pharmaceutical and agricultural products.

Fiji.—The export duty on copra has been reduced to 5s. per ton or part of a ton.

France and Algeria.—Hides and skins, crude wax, groundnuts, edible oils, etc., may be imported duty-free.

Germany (*Occupied*).—Goods in transit are exempted from export duty, including shellac exported to destinations other than unoccupied Germany.

Honduras.—Coconuts, copra and coconut oil may be exported free of duty.

Madagascar.—The statistical tax on packages of merchandise has been increased from 25 to 30 centimes per 1000 kg. or per cb. metre.

Newfoundland.—The export tax on seal oil has been suspended.

New Zealand.—The embargo on German and Austrian goods will be withdrawn on September 1.

Portugal.—A translation of the new customs tariff, which includes many raw materials and chemicals, is given in the issue for April 12.

South Africa.—The import duty on calcium carbide has been doubled, and the duties on paint, glass bottles, asbestos sheets, slates, sheet metal, matches, rubber tyres and inner tubes, have been revised. A " dumping " duty has been imposed on cement imported from Great Britain.

Spain.—Export prohibitions have been removed from petrol, petroleum, tanned hides and skins, untanned hides, and cement. The export duties on groundnuts, vegetable charcoal, soap, and tanned hides and skins have been withdrawn. The issue for April 5, gives a list of goods in respect of which certificates of origin must be supplied to secure reduced rates of duty. Among the goods included in the list are :—asbestos wares, hides, skins, iron and steel goods, purpurin of copper, copper alloys, scientific instruments, coal-tar derivatives, etc.

Tunis.—A " coefficient of increase " has been applied to glucose, mineral kermes and other antimony salts, and coal-tar derivatives. The export of sugar has been prohibited.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.	£23-£25 per ton. Very firm with little available. Complete absence of German supplies.
Acid Hydrochloric	4s. per carboy.
Acid Nitric	£24 10s. per ton. No signs of improvement.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw. is 70s., f.o.r. makers' works, with slight variations up and down, due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Steady demand. Continental inquiries more frequent.
Arsenic (white)	£70-£75 per ton. Market steady.
Bisulphite of Lime	£7 per ton. Packages extra.
Bleaching Powder	£10 10s. per ton d/d. No change. Spot demand poor.
Calcium Chloride	£6 per ton d/d.
Copper Sulphate	£27 per ton. Somewhat firmer
Potash Caustic, 88/90%	£35 per ton. Considerably advanced in value. No German supplies.
Potassium Bichromate	5¾d.-6d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£5 per ton. Normal.
Soda Caustic, 76%	£20-£21 per ton. Demand good, especially for the Continent.
Sod. Bicarbonate	£10 10s. per ton.
Sod. Acetate, 97/98%	£25 per ton.
Sod. Bisulphite Powder, 60/62%	ton lots £19 10 £19 10s. 5 £20 2 £20 10s. 1 £20 10s. 1 f.o.b. or f.o.r. London, 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Demand not quite so brisk, with better supplies.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide	£15-£16 conc. solid carr. paid. Better demand.
Sod. Sulphite, Pea Cryst.	ton lots £17 2 £17 10s. 1 1-cwt. wooden kegs included.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	8d.-1s. 3d. per lb.
Crimson	1s. 7d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6½d. per lb.
Sulphur, finest	£11 10s. per ton.
Arsenic Sulphide	2s. per lb.
Chromium Oxide	1s. 5d. per lb.
Lead Hyposulphite	8d. per lb.
Zinc Sulphides	7½d. per lb.
Carbon Bisulphide	£28 per ton.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Thiocarbanilide	2s. 6d. per lb.

WOOD DISTILLATION PRODUCTS

At the present time there is a fairly good demand for all Wood Distillation Products.

Acetate of Lime Brown	£10 per ton d/d.
Grey	£20 per ton d/d.
Liquor	9d. per gall, 32° Tw.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
Red Liquor	1s. 2d. „ „ 24° Tw.
	1s. 3d. „ „ 14/15° Tw.
Wood Creosote	2s. 6d. „ „ Unrefined.
Wood Naphtha, Miscible	6s. 6d. „ „ 60% O.P.
Solvent	5s. „ „ 40% O.P.
Wood Tar	£5 per ton d/d.

TAR PRODUCTS

Acid Carbolic Crystals	1s. 7d.-1s. 8d. per lb. Temporary lull in the demand, but makers are fully sold. Prices unchanged.
Crude 60's	4s. per gall. Little business passing.
Acid Cresylic, 97/99	2s. 1d.-2s. 3d. gall. More inquiry. Higher prices expected.
Pale 95%	1s. 11d.-2s. 2d. per gall. More inquiry. Higher prices expected.
Dark	1s. 9d.-1s. 11d. per gall. Little demand.
Anthracene Paste, 40%	4d. per unit per cwt. Price nominal.
Anthracene Oil—	
Strained	9⅝d.-11d. per gallon. Numerous inquiries but supply still limited.
Unstrained	9d. per gallon.
Benzole, Crude 65's	1s. 1d. per gall.
Standard motor	1s. 6½d.-1s. 8d. per gall.
Pure	2s.-2s. 4d. per gall.
Toluole, 90%	1s. 9d.-1s. 11d. per gall. Market steady.
Pure	2s.-2s. 6d. per gall. Fair inquiry.
Xylol	2s. 9d.-3s. 3d. per gall.
Creosote—	
Cresylic, 20/24%	11d.-1s. 1d. per gall.
Middle Oil Heavy Standard Specification	8½d. to 10d. per gall. Business active.
Naphtha—	
Crude	9d. -9¼d. per gall.
Solvent, 90/160	1s. 6d.-1s. 9d. per gall Better demand.
Solvent, 90/190	1s. 6½d.-1s. 7½d. per gall. Price steady.
Naphthalene Crude—	
Drained Creosote Salts	£7-£10 10s. per ton. Demand good. Supply short.
Whizzed or hot pressed	£11-£14 ton. Market active.
Naphthalene Crystals	£17 10s. per ton.
Flaked	£16 10s. per ton.
Pitch, Medium soft	190s.-200s. per ton, nominal. No business doing for this Season.
Pyridine—90/140	11s.-12s. 6d. per gall. Few inquiries. Price steady.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Business in Aniline Dyestuffs has not been quite so good during the past week, principally owing to the depressed state of the Textile Industry. This has been somewhat compensated for by orders from abroad which have come in a little more freely. Prices are very firm, and no reductions are expected in the near future.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride anhydrous	1s. per lb. delivered.
Aniline Oil and Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlor Phenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol, 29/31° C.	Fair demand with advanced prices in sympathy with Carbolic prices.
m-Cresol, 98/100%	2s. 3d. per lb. Fair demand.
p-Cresol, 32/34° C.	2s. 3d. per lb. Fair demand.
p-Dichlorbenzol	£70 per ton.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlor benzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene—48/50	8d.-9d. naked at works.
66/68	1s. 2d.-1s. 3d. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d, packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
a-Naphthol	2s. 8d. per lb.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d.-8d. per lb.
Nitronaphthalene	1s. per lb. d/d.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. d/d.
m-Phenylene Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. per lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sod. Naphthionate	2s. 8½d. per lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Although prices are much firmer, it is thought that quotations will inevitably go still higher as demand arises, as there is very little doing in the market at the present time. The export trade in these chemicals is, however, much better and promises to improve in the near future.

Acid, Acetic, 80%	£50-£53 per ton.
Acid, Acetyl Salicylic	3s. 4d. per lb. is the value to-day. It is firmly held at this figure.
Acid, Benzoic	2s. 3d. per lb. Unchanged with little inquiry.
Acid, Citric	1s. 8½d. per lb. for ton lots. Market very firm with tendency to advance.
Acid, Gallic	3s. per lb. for 2-cwt. lots, 3s. 3d. per lb. for 56lb. lots.
Acid, Pyrogallic, cryst.	5s. 9d. per lb. Price advanced.
Acid, Salicylic	2s. 3d.-2s. 6d. per lb. Buyers holding back but market firm.
Acid, Tannic	3s. 3d. per lb. still quoted.
Acid, Tartaric	1s. 3½d.-1s. 3¾d. per lb. As anticipated there has been a further rise in price and the demand is much greater. Raw materials continue to advance in price.
Amidol	9s. per lb.
Acetanilide	1s. 6d. per lb., with few orders about. This price is very low and must advance when stocks have to be renewed.
Amidopyrin	13s. 6d. per lb.—weaker.
Ammon. Benzoate	3s. 6d.-3s. 9d. per lb. advanced rate as anticipated.
Ammon. Carbonate B.P.	£37 10s. per ton.
Barbitone	17s. 6d.-20s. per lb. as to holder.
Benzaldehyde	3s. per lb.
Bismuth Salts	Unchanged. Steady market and good demand.
Bromides	All quite 1d. per lb. higher, with inquiry especially from abroad.
Calcium Lactate	2s. 9d. per lb. for English made.
Chloral Hydrate	4s. per lb., with little doing.
Guaiacol Carbonate	10s. per lb. is the value, though some holders are willing to clear their stocks at slightly lower rates.
Hexamine	4s. 6d. per lb. This price is well maintained.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. in 1-cwt. lots.
Magnesium Carbonate—Light Commercial	£38 per ton. Market fairly active recently.
Magnesium Oxide—Light Commercial	£85 per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Menthol	31s. per lb. original cases. Smaller quantities 32s. per lb. nett.
Methyl Salicylate	2s. 6d. per lb. in glass, tins being 2d. per lb. less.
Methyl Sulphonal	14s. 6d. per lb. is present value.
Paraformaldehyde	4s. per lb.
Paraldehyde	1s. 7d-1s. 9d. per lb. More enquiry.
Phenacetin	6s. 6d. per lb. Unchanged.
Phenazone	7s. 6d. per lb is now asked in some quarters. The price is certainly much firmer.
Phenolphthalein	5s. 6d. per lb—still better.
Potass. Bitartrate—99/100% (Cream of Tartar)	95s.-97s. 6d. per cwt., less 2½% for ton lots. Higher prices expected. Raw materials advancing.

Potass. Iodide	15s. 8d. per lb., cwt. lots packages free.
Potass. Permanganate	10d.-11d. per lb. Considerably firmer.
Potass. Sulphoguaiacolate	5s. per lb. is the value.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. Steady demand.
Resorcin	5s. 6d. per lb.
Salol	2s. 9d. per lb. Stocks are getting into small compass and the price now quoted is expected to advance before long.
Sod. Benzoate	2s. 3d. per lb. Spot supplies are firmly held at this figure.
Sod. Citrate	U.S.P. quality 2s. 2d. per lb.
Sod. Hyposulphite—Photographic	£15-£17 per ton according to quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d. per cwt. Poor demand.
Sod. Salicylate	2s. 8d. for Powder, 2s. 9d. for Crystal, are the new advanced rates, being 3d. per lb. higher.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. f.o.r. London, 1-cwt. wooden kegs included.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 4d. per lb.
Thymol	18s. per lb. for good White Crystal.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d.
Anise Oil, Red Ship Brand	2s. 1d.
Bergamot Oil	12s 6d. spot, 13s. 6d. forward.
Cananga Oil, Java	9s.
Cassia Oil, 80/85%	8s. 3d.
Cinnamon Oil, Leaf	4¼d. per oz.
Citronella Oil—	
Java 85/90%	4s. 3d.
Ceylon	3s. 3d.
Clove Oil	8s.-8s. 6d.
Eucalyptus Oil 70/75%	1s. 9d.
Lavender Oil, Mont Blanc 38/40%	13s.
Lemon Oil, Spot	3s. 1d. Higher prices are asked for forward delivery.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet, Spot	10s. 6d. Higher forward.
Otto of Rose Oil—	
Anatolian	24s.
Bulgarian	30s.
Palma Rosa Oil	17s.
Peppermint Oil—	
English, Mitcham	80s.
Wayne County	13s.
Japanese	6s. 3d.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	13s. ,, ,,
Amyl Acetate	2s. 6d. ,, ,,
Amyl Butyrate	8s. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (melting point 21/22° C.)	4s. 3d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. per lb.
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	3s. ,, ,,
Benzyl Benzoate	3s. ,, ,,
Cinnamic Aldehyde—	
98/100% Natural	14s. 9d. ,, ,,
Coumarin	15s. 6d. ,, ,,
Citronellol	22s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	18s. 6d. ,, ,,
Ethyl Phthalate	4s. 3d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	7s. 6d. per lb.
Iso Eugenol	16s. 6d. ,, ,,
Linalol ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	22s. 6d. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Ketone	35s. ,, ,,
Musk Xylol	9s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Terpineol	3s. 1d. ,, ,,

TRADE NOTE

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the above Act made during March, 1923, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee:—

The total number of applications received during the month was 539, of which 459 were from merchants and dealers. In addition, 30 applications were outstanding on March 1, making a total for the month of 569. These were dealt with as follows:—

Granted, 405 (of which 376 were dealt with within 7 days of receipt).

Referred to British makers of similar products, 105 (of which 96 were dealt with within 7 days of receipt).

Referred to Reparation supplies available, 37 (all of which were dealt with within 2 days of receipt).

Outstanding on March 31, 22 (mostly received immediately prior to Easter).

Of the total number, 569, of applications received, 467, or 82 per cent., were dealt with within 4 days of receipt.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, APRIL 27, 1923 No. 17

EDITORIAL

IT is an agreeable task to skim some old accounts of applied chemistry and see how the various processes have changed with the growth of the science and the manifold requirements of modern civilisation. A complete summary of the progress of chemical industry should be both interesting and valuable, but it is too great a task for this periodical unless a number of our readers will assist by pointing out omissions or mistakes, and by giving particulars which only those engaged in the different branches of manufacture can readily furnish. How many ingenious processes have been suggested and either never tried on a large scale or tried and found to be impracticable at the time of their trial! There was a process for obtaining nitrogen from the air by means of titanium oxide, put forward at a time when titanium oxide was not so easily procured as now, and when the fixation of atmospheric nitrogen or its conversion into ammonia were of no very obvious interest to commercial men. Do the same conditions apply to-day? The older text-books are full of such problems. And in browsing about one comes upon such a variety of topics; Tyrian purple directed our attention to Réaumur, and we found his life full of interest. Some of these older writers had a cheerful wisdom and instructive mirth which we confess appeal to us; armchair reading is, on the whole, preferable to study at a desk. A perusal of Faraday's account of the alloys of iron with chromium, platinum and other metals makes one wonder whether some new varieties of stainless steel will yet come on the market. It will be a long while before captive science yields her last retreat. The number of questions which would form suitable subjects for research was enormous a hundred years ago, and for every one which has been worked out a dozen new ones are waiting attention; and they have their bearing on arts and manufactures. The most abstruse points in electronic philosophy, in thermodynamics or the theory of allotropy, all create some new phase of thought, some fresh device or some unsuspected explanation which involves a supply or a demand previously lying hid. "The discoveries of each of the faithful, when weighed in a true balance, make a tiny portion of science, but by the anxious investigations of a multitude of scholars, each as it were contributing his share, the mighty bodies of the sciences have grown by successive augmentations to the immense bulk that we now behold."

* * *

A glance through our columns shows in how many branches of industry chemistry plays an important part, and it also shows how many different types of chemist use our columns as a means of making their views known or of learning items appertaining to the special feature which interests them or binds them together. If professional etiquette only permitted it, how this would be made apparent by a disclosure of the letters of criticism we receive! We wish we received more. The Society of Chemical Industry, of course, represents the most important part of our public and the membership of the Society, which slightly exceeds 5000, shows how many are interested in some way or other in applied chemistry, but this is not their only chemical interest. A considerable number of them follow the new discoveries of pure chemistry with serious attention and expect to find in our pages comparatively learned expositions of theoretical importance. Another large body of the Society is the Chemical Engineering Group which has now moved into more convenient quarters in Abbey House, Westminster. Its activities are occasionally relaxed—*nec semper tendit arcum Apollo*—as by the dinner to be held on May 4 at the Engineers' Club, Coventry Street, to be followed by a social evening with musical interludes—it was no doubt this which reminded us of Apollo. In another sphere of activity we remember the National Union of Scientific Workers who have absorbed or been absorbed by the British

Association of Chemists. Both these hitherto distinct organisations have made it their business to watch over the material rather than the intellectual rewards of workers and the meeting to be held on May 8, under the presidency of Mr. C. S. Garland, one of our few chemical Members of Parliament, will probably be largely attended. Elsewhere is a reference to the meeting of the Federal Council and the names of fully a score of other societies, institutes and associations are of frequent occurrence. Almost all the criticisms we have received, including those letters praising with faint—we forget the exact quotation—comment on the fact that we have devoted too much space to that type of article or news which the reader is not specially devoted to and too little to that variety which appears to him to be required. None the less we value such letters and have from time to time adopted suggestions made to us and as we grope about trying to feel our way into that position which such a journal as this demands, we do so with increased cheerfulness, knowing that the co-operation of our readers will in time enable us to continue an improvement which our vanity leads us to think is already beginning.

* * *

One who contributes every week to a chemical journal is never short of a subject; these exist in profusion. What is sometimes lacking is the inclination to write on the topics which are most urgently needed. Instead of settling down and doing the ordained work one finds " 'tis sweet to sit entranced, and muse thereon, in melancholy and godlike indolence." There is a feeling that the divine inspiration is somehow lacking and the drudge whose business is merely to condense some article of five columns into four inches likes, naturally enough, to consider himself one of those inspired by a muse. He repeats to himself :—

> Believe me there are tuneless days,
> When neither marble, brass nor vellum
> Would profit much by any lays
> That haunt the poet's cerebellum.

But bring the poet face to face with the alternative of poetry or starvation; how speedily the muse appears; some Discourager of Hesitancy would have no difficulty in making any contributor do his best and this pretence of inspiration is too often a mere cloak to conceal the laziness of the writer. The amateur can afford such a luxury and it matters to very few if he finds it more diverting to watch his aubretia and saxifrages than to write a breezy little sketch of tautomerism; but turn him into a professional, how his nature is changed :—

> The unhappy man, who once has trailed a pen
> Lives not to please himself but other men.

Come, forget the cuckoo and the feats of Chance, and get on with your Dyestuffs Act and statistics of the production of molybdenum in Armenia!

OTHER FACTORS INFLUENCING CO-ORDINATION

By Prof. T. MARTIN LOWRY, F.R.S.

1. Transfer of Electric Charges

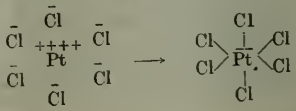
The two preceding articles of this series were already in the press before I had the opportunity of becoming acquainted with the conceptions that Mr. Sidgwick put forward at the meeting of the Chemical Society on March 1. It is, therefore, interesting to find that he lays special stress on an aspect of the problem which was not referred to in my previous article, although I have discussed it fully elsewhere, namely, the transfer of electric charges which accompanies the sharing of electrons.

It is a general rule that if one atom shares two electrons with another, but contributes *both* electrons to the common stock instead of only one, it acquires a positive charge, whilst its neighbour (which has acquired a half-share in two electrons not originally belonging to it) becomes negatively charged. I have illustrated this phenomenon, in a paper read before the Faraday Society on November 20, 1922, in the case of Meisenheimer's methylethylaniline oxide. In the oxidation of the amine from which this oxide is derived, a nitrogen atom carrying a complete octet unites with an oxygen atom carrying only as extet, to form a double-octet thus

$$:\underset{..}{\ddot{N}}:+\underset{..}{\ddot{O}}:=:\underset{..}{\ddot{N}}:\underset{..}{\ddot{O}}:$$

In this process the oxygen gains, and the nitrogen parts with, a half share in the two electrons which are held in common. The nitrogen therefore becomes positively charged and the oxygen negatively charged, as in the formula  . At the same time the valency of the nitrogen is increased by two units, from 3 to 5, by the addition of one covalency and one electrovalency. The transfer of electricity, which Sidgwick postulates in the case of co-ordinated compounds, is of a precisely similar character, and some of the effects of this transfer are set out below.

(*a*) *In the platinichlorides*, the outer shell of 32 electrons is completed by drawing in six duplets belonging to six chlorine ions. These six duplets are held in common by platinum and chlorine, and each element can claim an equal share in them. The platinum therefore gains six electrons, whilst each chlorine atom loses one. The result of this transfer is shown in the equation



The bivalent anion, $PtCl_6$, in the second formula is seen to contain six neutral chlorine atoms, held by covalencies, whilst the double negative charge of the anion is carried by the platinum.

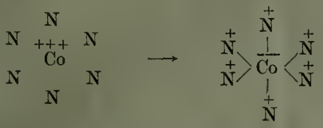
(*b*) *In the cobaltammines*, the transfer of electric charges between ammonia and the metallic ion on co-ordination is similar to that which occurs when an amine is converted into an amine oxide, *e.g.*,

$$NH_3+Me \rightarrow \overset{+}{N}H_3—Me$$

(where Me is a metallic atom) compare

$$NR_3+O \rightarrow \overset{+}{N}R_3—\overset{-}{O}$$

Each molecule of ammonia that is co-ordinated, therefore, acquires a positive charge, like that of an ammonium ion, whilst the cobalt gains an electron. The effect of this is first to neutralise and then to reverse the charge on the metal. Thus in the hexammines the charge on the cobalt is changed from $\overset{+++}{Co}$ to $\overset{---}{Co}$, as in the equation



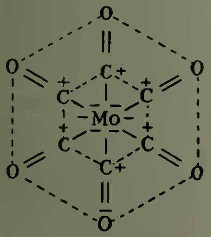
where for convenience of printing all the hydrogen atoms have been omitted.

(*c*) *In the metallic carbonyls* the sharing of electrons in the outer shell of the molecule converts a neutral into a polar system, since the addition of carbon monoxide to a metal must be represented by the scheme

$$:\ddot{O}::C:+Me \longrightarrow :\ddot{O}::C:Me$$

$$\text{or}\quad O=C<+Me \longrightarrow O=\overset{+}{C}—\overset{-}{Me}.$$

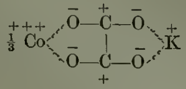
In the case of molybdenum hexacarbonyl, the formula would show a negatively charged metal attached through a inner octahedral shell of six positively-charged carbon atoms to an outer octahedral shell of six doubly-bound but neutral oxygen atoms.



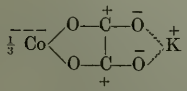
2—Ring Formation

Tschugaeff has pointed out (*J. pr. Chem.*, 1907, [ii], **75**, 153) that the formation of ring-systems is an important factor in co-ordination. In his experiments on optically-active co-ordination-compounds, Werner usually employed the oxalates. When these are represented in such a way as to show one oxygen of each carboxylic group attached to the metal, the ring system contains five atoms as in the formulæ III. and IV., and may, therefore, be compared with furfurane, pyrrol or succinimide.

III



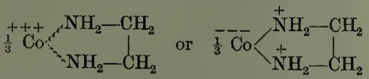
IV



In formula III. the cobaltic ion, $\overset{+++}{Co}$, is represented as attracting three bivalent oxalate radicals, of which (for convenience of printing) only one is shown. Formula IV. on the other hand shows the effect of the transfer of electric charges which results from the sharing of electrons, as discussed under (1) above. The malonates prepared by Jaeger may be formulated as containing a six-atom ring; the succinates prepared by Duff (*T.*, 1921, **119**, 385) contain a seven-atom ring; and Price and Brazier (*T.*, 1915, **107**, 1373), by introducing sulphur into the carbon-chain, have prepared compounds in which the ring contains eight atoms.

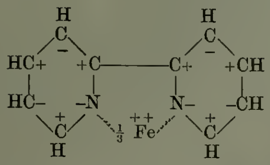
In the ethylenediamine compounds prepared by Werner the ring contains the same number of atoms as in the oxalates, as in the tervalent kation

V



A similar statement may be made in reference to tri-dipyridyl ferrous chloride, the bivalent kation of which may be represented as in VI.

VI

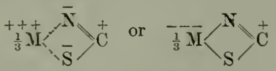


where again, for convenience of printing, only one of the three complexes attached to the iron is shown.

The stability of the oxalates may be associated with the well-known stability of five-atom rings. It should, however, be noticed that the two carbon atoms of each oxalate group are similarly charged; there is, therefore, a crossing of the polarities, which may be supposed to act as a factor antagonistic to co-ordination. In this respect a six-atom ring has a real advantage over a five-atom ring, since a chain of six atoms allows room for the concordant conjugation of three plus and three minus atoms ; at the same time the presence of six atoms introduces no serious strain in the ring. The advantage of being able to secure in this way a complete conjugation of all the atoms in the ring is clearly shown by the well-known stability of benzene, and, indeed, of *six-atom rings* generally, in conjugated compounds of the *aromatic* series, as contrasted with the greater stability of the *five-atom* rings in the saturated compounds of the *aliphatic* series, where conjugation does not " come into the picture."

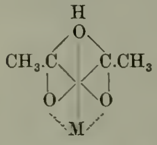
The factor of ring-formation in the side-chains is only of minor importance in the very stable co-ordinated compounds of tervalent cobalt, quadrivalent platinum, etc., since here the electrostatic attraction of the multivalent metallic ion, and the tendency for the metallic atom to complete its outer shell of electrons, exert such powerful forces that bipolar ions can be drawn into the system even when they give rise only to a four-atom ring, as in the thiocyanates

VII

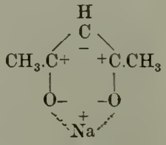


But in the case of metals of lower valency and smaller co-ordination-number, where the factors favourable to co-ordination are at a minimum, the question of ring-formation in the side chains becomes of predominant importance. Indeed, in the case of the alkali metals, the whole possibility of forming co-ordination compounds depends on bringing the metal into a stable ring-system, rather than on attaching to the metal a stable grouping of radicals, such as the octahedron which forms so conspicuous a feature in co-ordination-compounds of the type of the cobaltinitrites or platinichlorides. It is for this reason that in so many cases *tripolar* ions, rather than *bipolar* ions, are used to prepare co-ordination complexes.

This feature has been specially conspicuous in the work of Morgan, who has also, by assigning a centric formula VIII to derivatives of acetylacetone, directed attention to the analogy between these compounds and the aromatic ring-systems. The significance of the analogy is, however, seen much more clearly when polar formulæ are used as in IX.



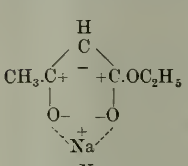
VIII



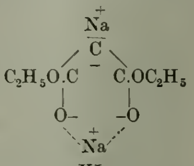
IX

The formula IX provides an excellent illustration of the significance of tripolar ions in co-ordination, the third negative pole being required merely in order to maintain the alternating polarities and so to continue the conjugation of the atoms right round the ring.

The sodium derivative of ethyl acetoacetate may be formulated in a similar way as X



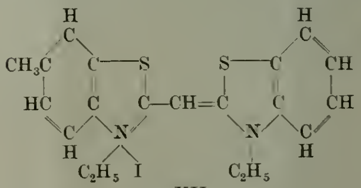
X



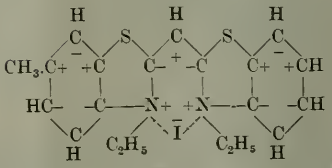
XI

The mono-sodium derivatives of ethyl malonate would be represented by a similar formula ; but in this case the second hydrogen atom of the ester (corresponding with the one that is shown as occupying a *para*-position to the sodium in IX and X) can also be replaced by sodium. This hydrogen atom is therefore mobile ; but when it escapes as an ion, or is replaced by a sodium ion, it leaves an electron behind on the carbon atom, which, therefore, acquires a double negative charge as in XI. It will be seen that in this case the third pole of the tripolar ion assumes an active instead of a passive part, but only in virtue of the double negative charge which it carries.

An example of a co-ordinated ring containing six atoms, in which a tripolar *kation* is co-ordinated with a negative radical, is provided by the thiocyanines, the " virtual tautomerism " of which was investigated by Mills and Braunholtz (*T*., 1922, **121**, 1489). The compound formulated as XII is shown as a co-ordinated complex in XIII, where it will be seen that the iodine is co-ordinated with the two ammonium radicals, but at the same time



XII



XIII

becomes a part of an aromatic ring similar to that postulated by Morgan in the acetylacetones. Ring-systems containing six conjugated atoms can also be detected in the formulæ of the sodium derivatives of nitrocamphor and of benzoyl-camphor, when formulated as co-ordinated compounds.

3—Summary

(*a*) The sharing of electrons which accompanies co-ordination has the effect of transferring electrons from the radicals to the metal, which also become united by covalencies.

(*b*) Co-ordination can be brought about, often under very adverse conditions, by making the co-ordinated groups part of a conjugated system. A conjugated ring-system containing three positively-charged and three negatively-charged atoms, as in benzene, is particularly favourable to co-ordination.

UNITED ALKALI COMPANY DINNER

The dinner given by the directors of the United Alkali Company at the Adelphi Hotel, Liverpool, on April 18, to celebrate the hundredth anniversary of the founding of the alkali industry in this country, was very largely attended. Sir Max Muspratt, Bart., presided, and amongst those who were present were Lord Doverdale, the Lord Mayor of Liverpool, Sir Benjamin Johnson, Sir A. Salvidge, Sir William Pope, Dr. E. F. Armstrong, Sir William Alexander, Sir Edward Brotherton, Bart., Major-General Thuillier, Sir J. Reynolds, Bart., Sir Ernest Oldham, Sir John Cowan, Sir R. Threlfall, Sir A. Bicket, Messrs. R. G. Perry, J. Tennant, A. T. Smith, H. Wade Deacon, Percy Ashley, J. E. Davidson, W. A. Tennant, Sir F. E. R. Becker, Sir Frederick Norman, Messrs. Roscoe Brunner, Robert Mond, H. S. Smith, Professors E. C. Baly, W. Ramsden, Green, Francis, J. F. Thorpe, I. Heilbron, Col. W. H. Stott, Dr. G. C. Clayton, the Prime Warden of the Dyers' Company, Messrs. G. H. Cox, A. Ree and W. Windus, the Mayor of Widnes, Dr. A. Holt, Messrs. W. J. U. Woolcock, Garrod Thomas, R. M. Bewick, Gaskell Holbrook, Stuart Deacon, Sir C. Mandleberg, Messrs. R. H. Davidson, C. A. Hill, H. Levinstein, Edwin Thompson, A. E. Rayner, Cecil Pilkington, W. A. Short, C. H. Nelson, Horace Muspratt, Sir James Ritchie, Bart., Sir L. Weaver, Messrs. E. P. Chance, L. B. Holliday, T. W. Stuart, John Kendrick, C. F. Ratcliffe, and T. L. Bailey.

After the loyal toasts, Sir Max Muspratt read a number of congratulatory telegrams, including the following: "Society of Chemical Industry sends congratulations on Anniversary of establishment of Alkali Industry, and recalls with pride that its senior Past President is your revered Dr. E. K. Muspratt. Armstrong, President." Sir Benjamin Johnson, High Sheriff of Lancashire, proposed the toast of His Majesty's Forces. The reply to this was made by Major-General Thuillier, C.B., C.M.G., who was Director of Chemical Warfare Services in France during the war. He spoke of the manner in which the chemical industry of Great Britain had contributed to the winning of the war, and mentioned that after the Germans had introduced poison gas, Great Britain successfully undertook the manufacture of this and poured on to the German troops twenty times the volume of gas our troops had to endure. He felt confident the chemical industry of the country would, whenever the occasion arose, respond to any call which was made to it. Mr. R. G. Perry, C.B.E., president of the Association of British Chemical Manufacturers, proposed the Alkali Industry, and briefly traced the history of this from the time of the French Revolution to the present day. He paid a tribute to the energy and acumen of the founder, Mr. James Muspratt, grandfather of Sir Max, and sketched the changes in the industry brought about by the Solvay process, applied in this country by that outstanding genius, Dr. Ludwig Mond, who, in co-operation with Sir John Brunner, had fifty years ago founded the firm of Brunner, Mond and Co. The Leblanc process and the Solvay process had made Britain supreme in alkali manufacture. The United Alkali Company were not only makers of alkali, but also the largest makers in Great Britain of sulphuric acid and heavy chemicals. Sir Ernest Oldham, deputy chairman of the Federation of British Industries, supported the toast.

Sir Max Muspratt, who was enthusiastically received, said that he felt proud of the industry which they were assembled to honour, and proud of his ancestry. The centenary celebration they were taking part in was a landmark of national defence as well as of peaceful development. Without a scientific basis their industry would vanish into ruin; and so they were trained to habits of clear thought, to an accurate sense of proportion, and to a complete readiness to adopt new methods which had survived the test of criticism. Mr. Roscoe Brunner, who also responded, mentioned how the descendants of the founders of the industry remained connected with it and claimed that the continuous association of great family names in the industry had been an asset of enormous value, and it had largely accounted for the splendid relationship which existed between employer and employed. Mr. A. T. Smith proposed the Merseyside Municipalities, to which the Lord Mayor of Liverpool and the Mayor of Widnes responded. Mr. W. A. Tennant proposed the health of the chairman, which was briefly acknowledged. A telegram of congratulation was sent by the Lord Mayor of Liverpool, in the name of the assembled guests, to Dr. E. K. Muspratt, the president of the United Alkali Company.

SIR MAX MUSPRATT, BART.

THE PRINCIPLES OF TRANSFERENCE OF HEAT

By GEOFFREY J. GREENFIELD, S.M., A.I.C.

(*Continued*)

Taking the following values:—steam to solid, $h_s=2000$, solid to liquid (not boiling), $h_l=50$. copper, $k_{Cu}=238$, lead, $k_{Pb}=20$, and assuming that the inside and outside areas of the copper tubing are the same, we may cancel all the A's in equation 3 ($A_{av}=A_1=A_2=A_3$). We have, before putting on the lead sheath,

$$\frac{1}{H}=\frac{1}{h_s}+\frac{l_{Cu}}{k_{Cu}}+\frac{1}{h_l}$$
$$=\frac{1}{2000}+\frac{\cdot014}{238}+\frac{1}{50}$$
$$=\cdot02056 \quad \text{Therefore } H=48\cdot7$$

Temp. diff. (entrance) $=366—172=194°$ F.
Temp. diff. (exit) $=366—214=152°$ F.
Average temp. diff. $=173°$ F.

Hence $\frac{Q}{A\theta}=H\,\Delta\,T=(48\cdot7)\,(173)=\underline{8420}$ B.T.U. per sq. ft. per hour.

After putting on the lead sheath, we have four resistances:—

$$\frac{1}{H}=\frac{1}{h_s}+\frac{l_{Cu}}{k_{Cu}}+\frac{l_{Pb}}{k_{Pb}}+\frac{1}{h_l}$$
$$=\frac{1}{2000}+\frac{\cdot014}{238}+\frac{\cdot0104}{20}+\frac{1}{50}$$
$$=\cdot02108 \quad \text{Therefore } H=47\cdot5.$$

Assuming the same temperatures as before,

$\frac{Q}{A\theta}=H\,\Delta\,T=(47\cdot5)\,(173)=\underline{8210}$ B.T.U. per sq. ft. per hour. That is, although lead is only *one-twelfth* as good a conductor as copper, yet the efficiency with the lead sheath is 97·5% $\left(\frac{8210}{8420}\,100\right)$ of that with bare copper tubes.

For most solids of industrial importance for the transmission of heat, physicists have determined the specific conductivity (k). For any substance this will vary to a certain extent with temperature, allotropic modifications, etc., but for practical purposes may be taken as constant. Film coefficients are more difficult to determine, and are affected by many external circumstances. Four cases must be considered —viz., the flow of heat from :—

(1) Gas to solid, or *vice versa*.
(2) Liquid (not boiling) to solid, or *vice versa*.
(3) Condensing vapour to solid.
(4) Solid to boiling liquid.

I. Gas to solid, and vice versa

(*a*) The gas is not in forced motion relative to the solid: *e.g.*, heat loss from the outside of a still, or a steam pipe, to the air of the room. In this case we shall expect the film to be a relatively thick one, since nothing but convection currents tends to tear it away; therefore, the film coefficient will be small, but it will increase with temperature, since viscosity decreases with temperature. Usually it lies between 1·0—2·0.

(*b*) The gas is flowing past the outside of a pipe. The commonest cases of forced flow outside pipes are those of air heaters, such as the Buffalo and the Sturtevant types, where the gas flows at right-angles to a bank of pipes, there being steam inside them. A higher coefficient will be expected here, because the velocity of the gas will tend to reduce the film. The following formula has been determined by Carrier for the Buffalo type:—

$$h=\frac{22\cdot3\ v}{1\cdot42+v}$$

where v=lbs. air passing per square foot of free area (measured at the point where the free cross-sectional area between the pipes is the least) per second.

(*c*) The gas is flowing inside a pipe. This will be dealt with later, under IIb.

II. Liquid (not boiling) to solid, or vice versa

(*a*) Liquid outside pipes. This is not often met with, except in preheaters for stills, in which fairly viscous oils are distilled. The film coefficient may vary between 10 and 100, depending upon the velocity, viscosity, etc.

(*b*) Liquid inside pipes (also gases, see Ic). Here the film will sometimes be very thin, for the body of the fluid is travelling parallel to the solid surface, and so exerts a *direct shearing stress* on the film. When a fluid flows very slowly in a pipe, each particle travels essentially in a straight line. This is called "viscous flow." In such a case, heat from the wall of the pipe must travel by *conduction only* through the liquid; that is to say, the "film" becomes the whole of the liquid. As the velocity is increased, a critical velocity is reached, above which the fluid breaks into eddies. This is called "turbulent flow." It is at velocities above the critical that fluids usually flow in practice. (The critical velocity depends upon the density and viscosity of the fluid and the diameter of the pipe.) Without going into this involved case fully, we may indicate the results of the latest work* as follows:—

The factors influencing the film thickness, and therefore the coefficient are:—

K = thermal conductivity of the fluid
D = diameter of pipe (inches)
u = velocity of fluid (f.p.s.)
ρ = density of fluid (lbs. per cu. ft.)
z = viscosity of fluid film relative to water at 68° F.

For liquids:—

$$h=\frac{22\cdot6K}{D}\left(\frac{Du\rho}{z}\right)^{0\cdot796}$$

The mathematical development of this equation is fully discussed in the article cited. Since the factor, $\frac{Du\rho}{z}$, is used equally for the calculation of flow of liquids and of gases in pipes, it is fairly safe to prophesy that McAdams and Frost will eventually devise an equation for gases, on similar lines to the above.

---

* McAdams and Frost, J. Ind. and Eng. Chem., 1922, **14**, 1101.

III. Condensing vapour to solid

When a hot, non-condensable gas is giving up heat to a solid surface, every molecule has, in effect, to come up to that surface, give up part of its energy, and then return to the body of the gas, thus opposing the passage of other molecules bent on the same errand. In the case of a condensable vapour, the molecules, having given up the necessary energy (*i.e.*, latent heat), do not have to leave the solid surface again, but remain there as liquid and trickle away. Thus the rate of flow of heat from a condensing vapour to a solid is very high. For pure steam the coefficient is as high as 2400. There will be a liquid film, thickness depending on the viscosity of the liquid. In most cases, and especially in some still-condensers, there will be some non-condensable gases mixed with the vapour, and this will have an adverse effect. For commercial steam a value of 2000 may be used. For other vapours than steam, the coefficient may be *roughly* determined from the equation[*]

$$h=h_s\left(\frac{u_w}{u}\right)\ \left(\frac{K}{K_w}\right)$$

where h_s and h=coefficients for steam and the vapour respectively, u_w and u=viscosities of water and the condensed vapour respectively (any units), K_w and K=thermal conductivities of water and the condensed vapour respectively.

IV. Solid to boiling liquid

This case is met with in stills heated by closed steam, in steam-jacketed pans, and in tanks in which reactions are conducted in a boiling solution kept hot by steam coils. This is a difficult case to investigate, and not much is known of it, since the coefficient will depend upon the disposition of the heating surface in the vessel, the density, heat capacity and viscosity of the boiling liquid, and also upon whether movement of the liquid depends upon natural convection or is assisted by a stirrer or circulating pump. The *overall* coefficient (steam to boiling liquid) has been known to have all values between 200 and 500. In enamelled apparatus it will be much less, owing to the high resistance of the enamel.

Radiation

Transmission of heat by radiation will, in general, be of interest to those engaged in high-temperature work, since it is at high temperatures that its effect becomes marked. Although the loss of heat from the surfaces of boilers, stills, and similar hot bodies situated in the open air, or in a room at atmospheric temperature, is loosely spoken of as "radiation loss," the above discussion makes it clear that it is partly due to conduction and convection. Radiation strictly means the transmission of heat from a body by means of heat waves in the ether (similar to light waves, but longer). These waves can travel through a gas or vacuum almost unimpeded, but are arrested on meeting a solid or a liquid. Like light waves, they can only, under ordinary circumstances, travel in straight lines. Of the energy in the wave the solid or liquid will reflect part, transmit part, and absorb part, just as it would with a light wave. Polished metallic surfaces reflect most of the radiant heat reaching them; glass and similar materials transmit most of it (in the wave form, and not by "conduction"); and all ordinary opaque, unpolished materials absorb most of it. A body which absorbs all radiant energy reaching it is said to be "perfectly black," and a body which absorbs, say 90%, is said to be "90% black," or to have a "coefficient of blackness of 0·9." White paper is about 80% black.

Not many substances other than the metals have been studied for "blackness," but for inorganic salts, and for most amorphous and rough-surfaced substances, including rusty and painted pipes, a coefficient of blackness of 0·9 may be taken. The following values for some metals were determined by Langmuir (Trans. Amer. Electrochem. Soc. 1913, 23):—Bright cast iron, 0·22; Iron (oxidised surface), 0·62; Monel metal, 0·43; Silver, 0·03.

The law of radiation, discovered by Stefan and Boltzmann, states that every body radiates heat in proportion to the fourth power of its absolute temperature, and also in proportion to its area. This means that, if we double the *absolute* temperature of a body, it will radiate sixteen times as much heat. Since all bodies are always radiating heat, the heat transferred from one body to another by radiation will be the excess of the heat received by the cooler body from the warmer, over the heat radiated by the cooler body. The simplest case is that of a small cool body surrounded completely by a larger hot body. In this case the heat received by radiation by the cooler body will be

$pAC'\ (T_1^4-T_2^4)$ B.T.U. per hour, where
p = coefficient of blackness of small body
A = area of small body
C' = universal radiation constant = $1{\cdot}62\times10^{-9}$
T_1 = temp. of large (hot) body in ° F. abs.
T_2 = temp. of small (cool) body in ° F. abs.

For practical use the equation may be written

$$\frac{Q}{\theta}=pAC\left[\left(\frac{T_1}{100}\right)^4-\left(\frac{T_2}{100}\right)^4\right]$$

where $C = C'\times10^8 = 0{\cdot}162$

---

[*] McAdams and Frost, *loc. cit.*, 1922, **14**, 17.

This may be applied to find the heat radiated from a furnace fire-bed to the boiler tubes above it, since none of the heat so radiated can get to any place save these tubes. In this case, A will be the surface of tube which one could see from the firebed—*i.e.*, the projection of the tubes on a plane parallel to the bed. In general, this will merely amount to the horizontal cross-sectional area of the combustion space. This is small compared with the total heating surface of the boiler, but plays an important part in comparison to its size. In a particular case, the area of the fuel bed was 37·4 square feet, and the total heating surface was 2010 square feet (37·4 is 1·9% of 2010). Yet, of the total heat imparted to the boiler, the amount calculated to be transferred by radiation was 2·9%.

The equation may also be applied to a steam pipe, or to a hot vessel, situated in a room. When a hot body is situated in the open air, the temperature of its surroundings (including clouds, if any) may be taken as that of the atmosphere, and it should be noticed that, when the sky is clear, that part of a body which is directly exposed to the sky is *radiating to the absolute zero*—*i.e.*, the T_2 term drops out. It must also be remembered that bodies such as are indicated in this paragraph are also giving up heat to their surroundings by conduction and convection through the air (see case Ia above). The following example may be given:—

The lagging has dropped off from 1 ft. length of a standard 6-in. pipe, which carries steam at 150 lbs. pressure. Assuming that the room is at 70° F., to find the heat loss per hour.

Area exposed = 1·73 sq. ft.
Steam temp. = 366° F. = 826° F. abs.
70° F. = 530° F. abs.
h (conduction) = 1·5

(*a*) Loss by conduction :—

$$\frac{Q}{O} = hA\Delta T = (1{\cdot}5)\ (1{\cdot}73)\ (366-70)$$
$$= 768 \text{ B.T.U. per hour}$$

(*b*) Loss by radiation :—

$$\frac{Q}{\theta} = pAC\left[\left(\frac{T_1}{100}\right)^4 - \left(\frac{T_2}{100}\right)^4\right]$$
$$= (1{\cdot}73)\ ({\cdot}9)\ ({\cdot}162)\ [(8{\cdot}26)^4 - (5{\cdot}30)^4]$$
$$= 976 \text{ B.T.U. per hour}$$

Total loss = 1744 B.T.U. per hour, or 2 lbs. steam condensed

In this article an attempt has been made to state in fairly simple language the main facts of a subject to which much attention is being paid at the present time. Mention may be made of "Heat Transmission, Technical Records Explosives Supply, No. 9," published by the Department of Scientific and Industrial Research, which is specially notable for the clarity with which examples are worked out. The subject has been very exhaustively investigated at the Massachusetts Institute of Technology, U.S.A., where, it is understood, a book is now in preparation.

FORTHCOMING EVENTS

Apr. 30. The Ceramic Society, Annual Meeting to be held in the Central School of Science and Technology, Stoke-on-Trent, at 7.30 p.m.

Apr. 30. Royal Society of Arts (Howard Lecture), at 8 p.m. "The Development of the Steam Turbine," by S. S. Cook. (Lecture 1.)

May 2. Society of Public Analysts, at Burlington House, Piccadilly, W. 1, at 8 p.m. (1) "The Quantitative Determination of Hemp and Wood in Papers containing these two Fibres," by W. Dickson, F.I.C. (2) "The Estimation of Fat, Lactose and Moisture in Dried Milks," by H. Jephcott, M.Sc. (3) "The Estimation of Lactose by the Polarimetric and Gravimetric Methods," by A. L. Bacharach, B.A. (4) "The Melting Point and Iodine Value of Refined Natural D. Camphor," by M. S. Salamon, B.Sc. (5) "The Presence of Barium and Strontium in Natural Brines," by A. G. Francis, B.Sc.

May 2. Institute of Metals, at Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W. 1, at 8 p.m. "The Inner Structure of Alloys," by Dr. W. Rosenhain, F.R.S.

May 3. The Institution of Sanitary Engineers, Caxton Hall, Westminster, S.W. 1, at 6.30 p.m. "The Relationship between Insanitation and Disease," by W. R. Hadwen, M.D.

May 3. The Ceramic Society, *Refractory Materials Section*, Town Hall, Bournemouth. Spring Meeting, 1923. Also on May 4.

May 3. The Chemical Society, Burlington House, W. 1, at 8 p.m. (1) "Change of Properties of Substances on Drying." Part II. H. B. Baker. (2) "The Sodium Salts of Phenolphthalein." H. Bassett and P. Halton. (3) "The Action of Thiosulphates on Cupric Salts." H. Bassett and R. G. Durrant. (4) "The Conditions of Reaction of Hydrogen with Sulphur." Part II. "The Catalytic Effect of Oxygen." Part III. "On the Mechanism of the Reaction of Hydrogen with Sulphur and Its Catalysts by Oxygen." R. G. W. Norrish and E. K. Rideal. (5) "Studies on Electrovalency." Part II. "The Rational Study of Optical Properties: Refraction a Constitutive Property." H. Hunter.

May 4. Society of Chemical Industry, Chemical Engineering Group, Engineers' Club, Coventry Street, W. 1, at 6.30 p.m. Annual General Meeting, followed by an Informal Dinner at 7.30 p.m., and later by a Social Evening. Members of the Group may introduce non-members to the Dinner and subsequent proceedings.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

June holds out the promise of a busy and interesting month. On the first the International Mining Exhibition at the Royal Agricultural Hall will be opened by Sir Philip Lloyd-Graeme, President of the Board of Trade. The exhibition has been organised by an influential committee of which Sir John Cadman is president, and is supported by the Institution of Mining Engineers, the Institution of Mining and Metallurgy, the Institution of Petroleum Technologists and similar well-known societies. The Governments of France, Belgium, Roumania, Mexico and other countries are sending exhibits and so are the Duchy of Lancaster, the Geological Survey and the Imperial Mineral Sources Bureau. Monsieur Paul Kestner and some of our other French friends are on the committee and we hope they will be able to pay visits to the exhibition. In any case a number of French chemists will come to London on the 14th to hear Professor C. Moureu, C.B.E., deliver his lecture to the Chemical Society on *Les gazes rares des sources thermales des grisons et autres gazes naturels.* Then on Sunday the 17th I suppose there will be an assembling at Cambridge. In addition to the social functions I hear there is to be a conference on Tautomerism opened by Prof. J. F. Thorpe, one on Catalysis opened by Dr. Eric Rideal, a paper on Oxidation in Animal Tissues by Professor Gowland Hopkins, and an account of Soap-solutions by Professor MacBain. These important topics and the transaction of the business of the various commissions will fill up the 18th, 19th, and 20th June pretty completely and then we shall have three strenuous days of the Annual Meeting of the Society of Chemical Industry. I feel sure that our President will begin his second year of office by delivering an address which will bring home to the general public as well as to the Fellows of the Royal Society the importance of chemistry to our national well-being.

The Alkali Centenary Celebrations

were the feature of last week. I find it difficult in a limited space to deal adequately with even the main features of the celebration, but the organisation of the dinner was excellent. The mechanical perfection of the arrangements was, however, overshadowed by something less tangible and more difficult to explain. The "atmosphere" pervading the whole of the visit was remarkable. How easily might the very gigantic character of the entertainment have proved top-heavy and wearisome. Nothing of the sort happened. We began the after-dinner speaking which followed the loyal toast, with Sir Benjamin Johnson and General Thuillier, who respectively proposed and replied to the toast of "His Majesty's Forces." Two good speeches delivered in an atmosphere of expectancy. Everybody had the air of waiting for something, and then Mr. R. G. Perry (President of the Association of British Chemical Manufacturers) rose to propose the toast of "The Alkali Industry." He began very quietly to fulfil his allotted task; in a few minutes he sketched the progress of the industry through the century. He then asked us to think of England without the alkali industry—Widnes without smoke, Northwich without salt and Port Sunlight without soap. Then came the disclosure of one of the secrets of the success of the industry, the good relationship between the employer and the employed. Here Mr. Perry struck the high idealistic note which was, indeed, maintained throughout. Sir Ernest Oldham followed, and then came the speech of the evening.

Sir Max Muspratt

was the first to reply to the toast; he admitted frankly that a dinner alone could never have drawn such a company together. It was the celebration of a century of progress, of development in the arts of peace and of national defence. Then he visualised the problems of the future, social, moral and labour. Material results were not enough: all their efforts would have to be concentrated on new problems. There was plenty of goodwill in the alkali industry in spite of superficial differences. If the goodwill continued they would overcome all their difficulties in the future as they had done in the past, and realise in the century before them an even more magnificent record than that they had already achieved. I very much doubt whether Sir Max Muspratt has ever achieved a better speech. In good delivery, restraint, sincerity and modesty, as well as in its matter it was excellent.

Mr. Roscoe Brunner

had to follow—not an easy task. He determined to compete with Sir Max in sincerity and and modesty. In a five-minute speech he paid a very generous tribute to Sir Max and the United Alkali Company. He humorously referred to two of the difficulties with which that company had to contend; their names, he said, were "Brunner" and "Mond." He followed up a thought of Mr. Perry's as to the value of the family interests in chemical firms, which has undoubtedly had a great deal to do with the freedom from labour troubles in chemical industry. And so we celebrated the centenary of the British alkali industry in typically British fashion. Mentioning our achievements with modesty and restraint: understating, rather than boasting of, our achievements; but with a clear eye and good courage for the future.

SOCIETY OF CHEMICAL INDUSTRY

NEWS FROM THE SECTIONS

YORKSHIRE SECTION

The fourth meeting of the session was held on April 16, Dr. L. L. Lloyd in the chair. Reference was made to the loss that the Society had sustained by the death of Mr. George Ward, one of the oldest members, and the Hon. Secretary was instructed to send the relatives of the deceased a letter of sympathy on their bereavement.

Mr. J. A. Reddie presented a paper, entitled "Some Notes on the Production of Alkali by Bacteria as registered by Different Indicators." At the Bradford sewage-disposal works the alkali content of the sewage invariably increased in passing through the filters. This was not due to the nature of the filtering medium, as it occurred even with quartz; the Bradford sewage was high in protein and albuminoid matter, and this unusual feature was undoubtedly due to bacterial action on the nitrogenous bodies. Accordingly, experiments were undertaken to elucidate the phenomenon. In the first series a standard broth of lemco and peptone was used and mixed cultures obtained by incubating the broth after inoculating it with filter washings. Tests were made daily over twenty days, the alkalinity as expressed by parts of sulphuric acid per 100,000 towards methyl orange and litmus, and the hydrogen-ion concentration being ascertained until the broth was used up. There was a very striking rise in the alkalinity, as expressed by (*a*) methyl orange from 53·9 to 521; (*b*) litmus from neutral to 225; (*c*) p_H figure from 6 to 9·67. Towards the end the alkalinity began to decrease. A portion was taken when the alkalinity reached 342 (towards methyl orange), reduced to 9·8 by adding dilute acid, and re-tested. Again the alkalinity increased, although with fluctuations. For example, the p_H figure was acid to begin with, from 5·9 to 2·6, and then began to rise.

The effect of adding various carbohydrates to the protein broth was next studied. During the first few days there was a sharp acid production, for the next fifteen days the figures were very erratic, and afterwards more normal figures for protein fermentation were obtained; a very vigorous carbohydrate fermentation set in before the protein fermentation. In another experiment, using two similar broths, only differing in their p_H figures, 7·168 and 2·9 (the first alkaline, the second acid), there was a preliminary instability, but the increase of alkali was more marked in the acid broth.

Another experiment in which alkalinity, hydrogen-ion concentration and free ammonia were ascertained was cited as showing the general course of the change, and the marked and wide discrepancies between the numbers.

A series of experiments was next carried out with one standard broth and pure cultures of 12 organisms, the majority of which occurred commonly in sewage, and one, *B. lacticus*, which did not. Phenolphthalein was added to the indicators studied. There was not the slightest difference with these cultures, except in degree; all produced alkali, the amount always rising steadily. The p_H figure was regarded as the best, the colour indicators showing wide differences.

In the discussion the chairman observed that with the complex fermentation and hydrolytic changes occurring with proteins any type of indicator was unlikely to give proper figures. Mr. F. W. Richardson said that the weak point was the use of a mixed protein medium, and suggested that further experiments should be made with pure proteins and bases like tryptophane with one organism, *B. coli communis*. Mr. W. J. Read emphasised his disbelief in indicators as giving figures of real alkali production, and quoted figures comparing methyl red and phenolphthalein. His results led him to conclude that the destruction of "buffering" substances led to the alteration in the hydrogen-ion concentration. Dr. N. M. Comber thought that results obtained with soil solutions were pertinent to the discussion. All indicators showed considerable differences and the electrometric method was the best at the moment. Mr. J. H. Garner spoke of the importance of the C : N ratio, as if the nitrogen was in excess to carbon alkali was produced. He asked if there was any evidence of nitrification and of the effect of carbon dioxide and carbonates on hydrogen-ion concentration.

Replying to the discussion, Mr. Reddie stated that the broth was used because it was standard, and might be used for comparison, but he recognised it was open to objection. He had found no sign of nitrification in the broth cultures; on filters it did occur, but not in Bradford as a rule; the alkali production might have something to do with this. Of the effect of carbon dioxide he had no knowledge. All organisms tended to give acid, but with certain foods they gave alkalinity.

MEETINGS OF OTHER SOCIETIES

INSTITUTE OF PHYSICS

The next lecture of the series on "Physics in Industry" will be delivered by Dr. J. W. Mellor, and the title will be "The Application of Physics to the Ceramic Industry." The meeting will be held at the Institution of Electrical Engineers, Victoria Embankment, W.C. 2, on May 9, at 5.30 p.m. Sir J. J. Thomson, president, will preside. The Board has kindly invited the members of the London Section of the Society of Chemical Industry to attend this lecture.

ACADÉMIE DES SCIENCES

The meetings held on March 19 and 28 were devoted to many interesting chemical problems. One paper was devoted to the petroleums of Auvergne. A boring sunk at Crouelle revealed the presence at a depth of 856 metres of clay, calcareous and other layers impregnated with petroleum. Geological evidence revealed by this boring suggested that the conditions of sedimentation in this district were favourable to the formation of petroleum. At a depth of 850 metres the bore reached a sandy layer, 40 cm. thick, containing 22 per cent. of oil, or about 1100 metric tons per hectare. It appears that 300 metres have still to be bored before the bottom of the Limagne basin is attained, a basin where it is expected petroleum will be found.

Monsieur l'Abbé Senderens communicated the results of work on the catalysis of alcohols by means of dilute sulphuric acid, and described a general method for preparing oxides and ethers.

Messieurs Bordas and Touplin described a new denaturant for ethyl alcohol. The new denaturant, intended to replace wood spirits, is extracted from the oils produced by distilling resins and tars of the Landes.

SOCIETY OF GLASS TECHNOLOGY

The sixth Annual General Meeting was held in Sheffield on April 18, the President, Prof. W. E. S. Turner, D.Sc., in the chair. The formal business included the election of the following officers :—*President :* Prof. W. E. S. Turner, D.Sc. (re-elected). *Vice-Presidents :* E. A. Coad-Pryor, B.A., W. J. Gardner. *Members of Council :* F. F. S. Bryson, M.A., B.Sc. ; Violet Dimbleby, B.Sc. ; Major G. V. Evers ; Col. S. C. Halse ; T. Teisen, B.Sc., C.E. *Treasurer :* J. Connolly (General) ; Wm. M. Clark, Ph.B. (American). *Hon. Sec. :* S. English, M.Sc. *Auditors :* E. Meigh, M.Sc. ; D. Wood, F.S.A.A.

The President's address on "The Year in Review in the World of Glassmaking" was taken as read, the main business of the meeting being a general discussion on "Works Organisation." Mr. W. W. Warren opened the discussion with a paper entitled "Organising for Production from Pot Furnaces." After a discussion on this paper, which had already been presented at the meeting in February (*cf. Chem. & Ind., p.* 235), the case for "Tank-furnace works organisation" was presented by Mr. T. C. Moorshead, who defined the organisation of manufacturing industry as a combination of men distributed in parts or groups with proper officials, managers, and foremen, and so co-ordinated that they were able with the aid of suitable machines and tools to produce a finished article efficiently. Such an organisation was necessary in order to define responsibility, but the man really responsible for the losses in plant efficiency was the active head of the institution. He agreed with the expert opinion that the average manufacturing plant had only 50 per cent. efficiency, and that 80 per cent. of this tremendous loss of efficiency was due to a lack of proper or efficient management. The causes of this loss of efficiency could be grouped under five headings :—

(1) *Faulty Raw Material.* The buyer, or preferably a works chemist, should investigate the sources of supply to make provision for constant and regular supplies, keep a sufficient quantity in store at all times in order to ensure against stoppage in case of failure of deliveries, and analyse the materials frequently for purity and conformity with specifications.

(2) *Poor Labour.* This was a difficult problem and should be dealt with at the source. Provision should be made for carefully investigating every application for work in the plant, and the applicant should be interviewed by a man who is a good judge of human nature.

(3) *Poor Attendance.* It was a fundamental principle that a man's work should be interesting. This might be done by ensuring that the employees understood what they were doing and why. Weekly managers' and foremen's meetings should be held, complete records or minutes of which were kept and copies circulated to those who were present.

(4) *Large Labour Turnover.* To prevent the wastage due to this cause the work should be made agreeable. It was also necessary to regularise it or make it steady, and every man should be given identity, and made to feel that his progress was being watched and interest taken in him.

Many manufacturing plants actually made a careful analysis of each job, the main idea being to find what the requirements of each job were, both with respect to physical strength and mental capacity. When this was done, the results were tabulated and printed on a card in the form of job specifications. Then, when new men were employed, they were selected in conformity with these specifications and adjusted to their positions in such a way as to make them contented and turn out the largest possible output.

(5) *Machine or Mechanical Breakdowns.* This was the least wearisome cause of loss of efficiency. In 9 cases out of 10, machine breakdowns were due to lack of foresight : failure of the man responsible for the particular machine to anticipate troubles, failure to see that spares for vital parts of the various machines were kept in store ; and failure to keep all moving parts properly oiled and the machines clean.

Mr. Moorshead concluded his paper by emphasising the great responsibility resting on the foreman and gave some suggestions as to what questions a manager might ask himself in selecting his foreman or determining his capabilities.

CHEMICAL SOCIETY

An ordinary scientific meeting was held on April 19, the newly-elected president, Prof. Wynne, being in the chair. A vote of condolence on the death of Sir James Dewar was passed, and the names of the following Fellows were read as having died since the last meeting: G. Embrey, H. H. Froysell, J. S. Wilkes, R. D. Pettigrew, Henry Walker, T. Howard. Five papers were read.

(1) "The influence of nitro-groups on the reactivity of substituents in the benzene nucleus. Part VII. Reactions of 2 : 5- and 4 : 5-dinitro-m-xylenes," by E. Ibbotson and J. Kenner. Dr. Kenner summarised this paper from the standpoint of the Lapworth theory of induced polarity and discussed the importance of the key atom, the possibility of forecasting the position in which substitution would take place, and the chemical reactivity of the products.

(2) "The chemistry of the three-carbon system. Part I. The influence of the cyclohexane ring on the $\alpha\beta$–$\beta\gamma$ change," by S. F. Birch, G. A. R. Kon and W. S. G. P. Norris. Dr. Kon explained many of the reactions in a three-carbon system on the assumption that tautomerism occurred in the same way as with ethyl aceto-acetate. It was suggested that various kinds of tautomerism might account for different reactions.

(3) "On the promotion of catalytic reactions. Part I.," by S. Medsforth, who pointed out that nickel might act both as a catalyst and promoter, or the metal might act as the catalyst and the oxide or sub-oxide as promotor. An added promotor caused a reaction to take place more rapidly as the catalyst was then left to do its work unimpeded. The consideration assumed the formation of an intermediate compound and the dehydration hypothesis to explain the function of the promotion. Experimental results were given and a method outlined for testing reactions according to various groups present in the substance catalysed. The high efficiency of the incandescent mantle was given as an illustration of catalysis, the 99 per cent. of thoria acting as the catalyst and the 1 per cent. of ceria as the promotor. Dr. Rideal pointed out the importance of surface tension and surface action in catalyst reactions. As an instance of the latter he mentioned that the decomposition of calcium carbonate crystals occurred at the interfaces whereas in the readsorption of carbon dioxide the whole surface was concerned.

The last two papers were: "The action of halogens on phenylhydrazones. Part I. The action of bromine," by J. E. Humphries, E. Bloom and R. Evans, and "The mobility of symmetrical triad systems. Part II. The conditions relating to systems terminated by the *o*-phenylene group. Derivatives of indene," by Dr. C. K. Ingold and H. A. Piggott.

FARADAY SOCIETY

A meeting was held on April 23 in the Chemical Society's Rooms, Burlington House, and three papers were read.

Dr. E. K. Rideal presented a paper on the "Rate of Hydrogenation of Cinnamic and Phenyl-Propiolic Acids." The investigation bore on the mechanism of hydrogenation in a solution of two salts, sodium cinnamate and sodium phenyl-propiolate, differing from one another only in the possession of a treble bond in the latter in place of a double bond in the cinnamate, the object being to determine whether the reaction velocity really conformed to a reaction of zero order, and whether the reaction velocity was really the velocity of diffusion of the hydrogen to the colloidal palladium. Colloidal palladium sol was used and electrolytic hydrogen free from oxygen was utilised in all cases. It was concluded that the two salts in solution underwent hydrogenation at equal rates of hydrogen uptake in the presence of palladium sol when present in large quantities. The rate of hydrogenation depended on the rate of supply of hydrogen to the palladium and was proportional to the square of the shaking speed, the reaction velocity being of zero order. For small quantities of palladium the reaction velocity was proportional to the palladium concentration and the phenyl-propiolate absorbed hydrogen at roughly twice the rate of the cinnamate. Above certain limits the rate was independent of the shaking speed. The reaction velocity was, within limits, independent of the salt concentration. All sols began reaction with a velocity curve of zero order, but terminated in a reaction velocity curve of the first order. It was found that both salts undergoing hydrogenation as well as the hydrogen were adsorbed and it was assumed that the quantity of active sols adsorbed was independent of the bulk concentration down to extreme dilutions, but the limiting concentration with old sols rose, due to a decrease in adsorptive power. The adsorbed salt remained on the surface until completely hydrogenated, so that the rate of hydrogenation of phenyl-propiolate was the same as that of cinnamate, the former taking up two molecules of hydrogen in the same time as the latter took up one.

A note on the "Coagulation of Milk by Acid" was presented by L. Anderson, B.Sc., who described work designed to obtain information on the behaviour of casein and the protection of the fat globules, particularly regarding their resistance to coalescence when treated with acid and alkali respectively. On adding hydrochloric acid to milk of various dilutions casein was precipitated, the amount of precipitation increasing with increasing amounts of acids until a maximum rate of settling of the casein occurred. The amount of acid required to give this maximum rate of settling was inversely proportional to the dilution of the milk. That the fat globules were carried down mechanically by the casein was shown by the fact that on dissolving the curd the uncoalesced globules of fat rose to the surface. At higher concentrations of acid, casein was again precipitated; this precipitation was the salting out of the casein chloride by hydrochloric acid. Decinormal caustic soda would not cause coalescence of the fat globules, and it was concluded that casein was the protective agent preventing the fat globules from coalescing. Emulsions of benzene and olive oil in casein solution behaved similarly to milk with respect to acid and alkali.

Mr. A. Taffel read a paper on the "Temperature of Maximum Density of Aqueous Solutions." The author observed that the density of pure water passes through a maximum at 4° C., and that aqueous solutions of salts have a temperature of maximum density of less than 4°. Despretz was the first to show that the lowering of the temperature of maximum density below 4° was directly proportional to the concentration of the salt in solution. The present paper was devoted to an attempt to account for the effects produced on the temperature of maximum density of water by various solutes. The decrease in the total volume occurring when 1 gram of a substance was dissolved in water at a definite temperature to give a solution of a definite concentration was termed the "solution-contraction" for that substance at that temperature and concentration. If the solution-contraction increased with a decrease in the temperature at which solution occurred (this seemed to be a general rule), then the temperature of maximum density of the solution was below 4° C. If the solution-contraction, however, decreased as the temperature of the solution was lowered, as occurred with methyl, ethyl and propyl alcohols, then the temperature of maximum density of the solution would be above, at or below 4°, according as the rate of decrease of the solution-contraction was greater, equal to, or less than the rate of thermal contraction of the solute. The specific effect of ions and molecules on the depression of the temperature of maximum density of water resulted from their specific solution-contraction.

Messrs. J. H. Shaxby and J. C. Evans presented a paper on the "Variation of Pressure with Depth in Columns of Powders," in which they showed that the general form of the pressure-depth curves agreed well with the equation $p_a = p_m(1 - Ce^{-Kx})$ in which p_m was the maximum pressure and C and k constants.

Two papers on (*a*) "The Compressibility of Powders" and (*b*) "The Distribution of Densities in Columns of Compressed Powder," were contributed by Dr. E. E. Walker. In the first paper, the author described methods for measuring the resistance of powders to compression by static loads and blows from a falling weight, and the investigation of the resistance offered by powders made from various organic and inorganic substances to both these forms of compression. A theory was put forward to explain the different forms of load-volume curves. The second paper described measurements of local densities in columns of compressed powder, and gave a curve deduced to show the distribution of pressure in a column of compressed powder.

ROYAL SOCIETY OF ARTS

Sir R. Redmayne, K.C.B., read a paper entitled "A Review of the Base Metal Industry, with Special Reference to the Resources of the British Empire," at the meeting held on April 20.

After reviewing the position of base-metals during and after the war, Sir R. Redmayne gave a detailed account of the chief non-ferrous metals, of which an abstract is appended.

Copper is the metal of which the British Empire has the smallest domestic supplies. In 1919, the British Empire contributed only 6% to the world's output of copper; in 1920 7·5%, and in 1921 8·5%. The country chiefly affected by the decline in production since 1917 is the United States, which produces normally over 50% of the total world's output, and controls a still larger production by ownership of mines in other countries, notably Chile and Peru. The pre-war consumption (1913) of the three greatest copper consumers in the world, was as follows:—U.S.A., 340,000 t.; Germany, 255,000 t.; Great Britain, 138,000 t., or, in the case of Great Britain, one and a half times the Empire's output. From the point of view of potential resources the British Empire contains extensive areas of copper-bearing ground that are worth investigation. Canada presents a most likely source of increased supply, particularly British Columbia. The production from the Otavi mines in South-West Africa is also increasing, and production may soon be expected on a larger scale from Papua, where are extensive deposits of high-grade ore. Production by the Union Minière du Haut Katanga, in the Belgian Congo, largely controlled by British capital, has increased from 30,000 tons in 1922 to over 40,000 tons in 1922. In Northern Rhodesia the Bwana M'Kubwa Copper Co. has proved the existence of over 7,000,000 t. of ore carrying an average of 4% of copper, and proposes to apply a special ammonia process in treating the ore.

The chief hope for a gradual reduction in the price of metal would appear to be in the wider application of flotation methods for concentrating the ore and new leaching processes for extracting the metal from the ore, as they would permit the vast deposits of low-grade ore in Chile, etc., to be worked. The treatment of low-grade oxidised copper-ores by leaching processes has developed greatly in recent years.

Several processes of leaching with sulphuric acid are now in operation; in some, the copper is precipitated by scrap or sponge iron, in others by electrolysis. A fact worthy of note is that the Anaconda Copper Mining Co. has gradually acquired the control of a considerable portion of the world's copper resources, including the Chuquicamata mine, which has reserves of ore estimated (1916) at 700 million tons, equivalent to 14 million tons of metallic copper.

Lead.—The British Empire is in a somewhat better posision in respect of lead than as regards copper. In 1919, 1920 and 1921 the Empire produced, respectively, 17½, 12½ and 24 per cent. of the world's production. But the amount produced within the Empire falls short of the amount imported into the United Kingdom, viz., over 200,000 t. of lead in one form or another, but a certain proportion is exported, either as pig lead or manufactures of lead, to the extent of between 70,000 and 80,000 t. Although there was a marked increase in the production of lead during the war, the increased output was attained by the sacrifice of high-grade ore-reserves rather than by extension of smelting works. It appears that the lead-mining industry is one of the few branches of the base-metal mining industry which is not over developed. No great discoveries of lead ore have been made in recent years, and it looks as if the developed resources were being exploited near to, if not up to, their full capacity. The United States is the largest producer and the greatest consumer of lead in the world, but Spain and Australia both exporting more lead than America. In 1913 82% of the world's production was derived as follows:—United States, 37%; Australia, 20%; Spain, 15%; Germany, 6%, and Mexico, 5%. Britain is the largest importer of lead in the world; before the war Spain supplied 38% of our requirements; Australia, 28%; U.S.A., 15%; and Mexico, 10%.

The perfecting of the flotation process of concentration has made it possible to re-treat considerable accumulations of zinc-and-lead-bearing tailings and residues at the Broken Hill Mines of New South Wales. Our resources of lead within the Empire are considerable. Burma alone should contribute greatly, and home supplies will probably be found to be worth further exploitation as foreign costs increase.

Zinc ores are closely associated with those of lead, and the two metals are in many cases obtained from the same mine. Just as in the case of lead, the United States of America far exceeds any other country as a producer of zinc. In 1919, 1920 and 1921 the contribution of the British Empire to the zinc production of the world was 11%, 6% and 30% respectively, of the world's production, the low figure for 1920 being due primarily to the strike at the Broken Hill Mines in Australia. In 1913 the United States consumed 308,000 t., Germany 228,000 t., and the United Kingdom 191,000 t. Those three countries are the chief consumers of the metal. The British Empire meets only one-third of the requirements of the Mother Country.

The two most noticeable features in respect of zinc at the present time are:—(1) The rising production of electrolytic zinc, notably in Tasmania, Canada and the United States of America; and (2) the fact that, as a result of the war, the world's smelting capacity of zinc is largely in excess of the ore-production. The capacity in this respect of the United States alone is now 800,000 t. per annum. The electrolytic process is now an acknowledged commercial success, although still the greater part of the production is due to distillation.

Tin.—The Empire position in respect of tin is different from that of the three previously named metals, inasmuch as the Empire is the chief contributor to the world's production, accounting for more than half of the annual output. The Malay States is the chief producer, contributing over 36% of the world's output; then follow Bolivia and the Dutch East Indies, with about 20 and 15% respectively. At present the production and consumption of tin appear to balance. Normally the United Kingdom imports about 35,000 t. of tin ore, about 8,000 t. being from British Possessions, and 40,000 t. of metal, which, with the exception of 2000-3000 t., is derived from British Possessions. The re-exports in a normal year are about 3000 t. of ore, and 40,000 t. of unwrought tin. The balance, about 32,000 t. of tin ore, together with the domestic production, which in 1913 was 8,355 t., was apparently sufficient to meet the domestic requirements of the United Kingdom. Few new sources of tin have been discovered in recent years, although it appears probable that the Belgian Congo is likely to become an important producer in the not far distant future. It would seem that unless really extensive deposits are discovered, tin will be one of the first base metals to be exhausted. The smelting of tin ore is concentrated in few hands, although the tin-smelting capacity of the world is well in excess of the annual supplies of ore. In this respect the Straits Settlements heads the list with a capacity of about 58,000 t. of metal, Great Britain following with a capacity of about 34,000 t., and the United States with a capacity of 30,000 t., the total world smelting capacity being about 175,000 t, per annum.

Aluminium in the form of silicate is perhaps the most plentiful metalliferous mineral in the world, but owing to difficulty in extraction it is only of late years that it has been used on a large scale commercially. Bauxite, which contains from 30 to 60% of alumina and from 0·5 to 20% of silica, is the chief source of the metal, but only comparatively pure mineral can as yet be used profitably. In 1913 the British Empire accounted for little over 1% of the world's production of bauxite and in

1921 about 9%. The increase in the contribution from the British Empire is due to the development of the deposits in British Guiana. The United States is the chief producer, contributing 43% (1921) of the world's output. France comes next with 25% (1921). Besides the deposits of British Guiana there exist rich deposits of bauzite in India and the Gold Coast. In the former case development will depend on local demand, small at present, for the metal, and in the latter case difficulties stand in the way of transporting the ore to a place convenient for its reduction.

In conclusion Sir R. Redmayne said it would appear that stocks of the base metals were being absorbed, the demand was increasing, and a gradual improvement might be foretold with reasonable certainty. The feeling that we were on the eve of better times might be translated into certainty were the United States to cease from erecting tariff walls, and France and Germany to settle their difficulties. One effect of the tariff situation must be to force us to seek new sources of raw materials and to develop new markets.

INSULIN

The Medical Research Council announces that the remedy for diabetes, insulin, is now prepared in sufficient quantities to be placed on the market. A committee has been appointed by the Minister of Health to arrange for distribution to the medical profession and provisional authority has been given to the British Drug Houses, Ltd., in conjunction with Messrs. Allen and Hanburys, and to Messrs. Burroughs, Wellcome and Co. to distribute the remedy. A supply is also to be obtained from Eli, Lilly and Co., of Indianapolis, U.S.A. On the advice of the above-mentioned committee, supplies, while production is limited, will be restricted to hospitals and registered medical practitioners who have proper facilities for making accurate blood-sugar determinations in order to use the remedy in minimum quantity. Messrs. Burroughs and Wellcome, whose reputation in the field of biological productions is well known, has issued "Wellcome Brand Insulin" as a sterile watery solution in rubber-capped phials containing 100 units in 5 c.c. of solution. The dose is indicated in units, the average dose being 10 units injected subcutaneously twice a day. It is calculated that a unit will enable the patient to take at the ensuing meal 1·4 grams of additional carbohydrate, or its equivalent, without excreting sugar. An account of the production of insulin by the British Drug Houses, Ltd., in conjunction with Messrs. Allen and Hanburys was given in the last issue of *Chemistry and Industry*.

CORRESPONDENCE

THE TITLE "CHEMIST"

Sir,—Anent observation by "Eye-witness" in *Chemistry and Industry* of March 29, it may be of interest to you to learn that at the time the Institute of Chemistry was founded there *was* a good deal of discussion in point of fact concerning the possible clashing of interests between the Institute and the Pharmaceutical Society. I, myself, had several discussions with Mr. Carteighe concerning the matter, and at the time I regarded the position shown by him in respect of the Institute as rather protective of the interests of the Pharmaceutical Society than anything else.—I am, Sir, etc.,

C. T. Kingzett

Newlands, Weybridge
April 6, 1923

Sir,—Is it not time that the unseemly squabble about the use of the terms "chemist," "pharmacist," and "doctor" was brought to a close? It is not only unprofitable; it is worse, it is unprofessional and undignified.

After all, "the rank is but the guinea's stamp, the man's the gowd for a' that" and it may happen that a censorious world will think that those who are so keen in their insistence on the guinea's stamp are—shall we say?—a little doubtful of the fineness of their gold. It is the opinion of many who are well qualified to judge, that there is no title so becoming a gentleman as "mister."

It might be pointed out, too, to "Doctor of Science," since he is so interested in splitting etymological hairs, that unless he is a member of the teaching profession, he is not strictly entitled to the designation "doctor" (L. *docere*=to teach).—I am, Sir, etc.,

Harold Hunter

London, E. 12
April 10, 1923

Sir,—Why sigh for the moon when you know you can't get it?

Why ask Parliament to prevent drug-sellers being called chemists as they have been for ages past? Supposing Parliament did so, would that make the public drop the title? Can you impose a fine on every one who says he is going to a *chemist* to buy some opodeldoc after such a law is passed? Not you, but the public decides. It is quite hopeless to expect all this.

We have either to adopt, and restrict for ourselves, some new appellation, or to look backwards for some old one not already adopted by the drug-seller.

The names druggist, chemist, pharmacist, dispenser, etc., are already applied by the public to those who sell drugs and they will continue to do so whatever law is passed. Our first title was alchemist, the only one left to us is "analyst." Why not use it? Legalise it at once before that title too is snapped up by the drug-compounder. It may be urged that professors, teachers, works' advisers, consultants are not strictly "analysts." Well, if they have never used a test-tube they certainly have no claims to be either chemists or analysts.—I am, Sir, etc.,

A. W. Stokes
(Public Analyst)

Paddington Green
April 16, 1923

Sir,—Would it not be more practical, instead of claiming the title of chemist and endeavouring to persuade the chemist, who dispenses drugs, to forego his claim, to adopt another designation?

I would suggest reviving the term "alchemist." This term is now obsolete but as a profession we are the direct inheritors. The word alchemy, which is still sometimes used, conveys to the layman the suggestion of inquiry and discovery, so would not confuse him.

There are subsidiary arguments for the word alchemist. The professional chemist was originally usually called an analytical chemist, and if the broadest sense of the word analytical is taken, analytical chemist still describes members of the profession, particularly consultants, very well. As analytical chemist is too long, why not regard alchemist as a euphonic contraction for it? Or one could argue that an alchemist takes all chemistry for his province and is not restricted to the narrow field, which in the public mind is that of the chemist.

A united effort to establish and define the word alchemist would arouse far more useful public interest in the profession than anything in the nature of a squabble with the chemists and druggists. As a Scotsman I also think it would probably cost less.—I am, Sir, etc.,

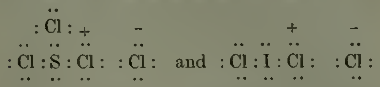
"CAUTION TO INVENTORS"

Sir,—In case the matter may not have been brought to your notice already, it has been suggested to me that I should draw your attention to "Caution to Inventors," which has been inserted by the Comptroller-General of Patents in the Illustrated Official Journal at the request of the Chartered Institute of Patent Agents:—"Inventors are advised to beware of suggestions such as are now being issued from a German source to the effect that, for reasons obscurely stated by the German writer, the British inventor should co-operate with him and in particular should send him by registered letter a sum of money. The communication is fraudulent, and on no account should money be sent."—I am, Sir, etc.,

Richard B. Pilcher
Registrar and Secretary
Institute of Chemistry, London
April 18, 1923

THE FORMULÆ OF SULPHUR TETRACHLORIDE AND IODINE TRICHLORIDE

Sir,—The method of formulation used by Mr. G. W. F. Holroyd in his letter of April 6, when applied to sulphur tetrachloride and iodine trichloride leads to the formulae



$$:\underset{\cdot\cdot}{\overset{\cdot\cdot}{Cl}}:\underset{\cdot\cdot}{\overset{\substack{\overset{\cdot\cdot}{:Cl:}\\\cdot\cdot}}{S}}:\underset{\cdot\cdot}{\overset{\substack{+\\\cdot\cdot}}{Cl}}:\quad:\underset{\cdot\cdot}{\overset{\substack{-\\\cdot\cdot}}{Cl}}:\quad\text{and}\quad:\underset{\cdot\cdot}{\overset{\cdot\cdot}{Cl}}:\underset{\cdot\cdot}{\overset{\cdot\cdot}{I}}:\underset{\cdot\cdot}{\overset{\substack{+\\\cdot\cdot}}{Cl}}:\quad:\underset{\cdot\cdot}{\overset{\substack{-\\\cdot\cdot}}{Cl}}:$$

which indicate that these substances would be electrolytes.

The cryoscopic behaviour of solutions of iodine trichloride in phosphorus oxychloride has been investigated by Oddo (*Gaz. chim. ital.*, **31**, II., 151, 1901); and Abel and Halla (Abegg's *Handbuch der anorg. Chem.*, IV., 2, p. 484) quote the equation:—

$$ICl_3 \rightleftarrows ICl_2 + Cl'$$

as probably representing the dissociation found to occur. Further support for this view is derived from the work of Walden (Abegg's *Handbuch*, *loc. cit.*), who finds that in non-aqueous solution iodine trichloride behaves as an electrolyte, the ionisation increasing with dilution.

On this method of formulation there would be considerable analogy between the formulae for iodine trichloride and di-phenyliodonium hydroxide:—

$$:\underset{\cdot\cdot}{\overset{\cdot\cdot}{Cl}}:\underset{\cdot\cdot}{\overset{\cdot\cdot}{I}}:\underset{\cdot\cdot}{\overset{\substack{+\\\cdot\cdot}}{Cl}}::\underset{\cdot\cdot}{\overset{\substack{-\\\cdot\cdot}}{Cl}}:\quad\text{and}\quad C_6H_5:\underset{\cdot\cdot}{\overset{\cdot\cdot}{I}}:\overset{+}{C_6H_5}:\underset{\cdot\cdot}{\overset{\substack{-\\\cdot\cdot}}{O}}:H$$

and, as is well known, the latter is a strong electrolyte.—I am, Sir, etc.,

"ORGANIC" CHEMISTRY

Sir,—The communications of Sir Wm. J. Pope and the letter from Sir A. Colefax in your January 5 issue, although apparently antagonistic, really serve to impress one with the same conviction, viz.:—the futility of the continued use of the word "organic" as a general term of classification in chemistry.

Sir Wm. Pope's series of quotations only emphasise the fact that all chemists who have considered this matter have realised the difficulty of formulating a logical definition. The majority of them have decided to abandon logic in favour of simplicity and have put forward definitions, which are certainly simple and comprehensible (so far as they go), but which ignore totally the meaning of the word "organic" and are a constant source of trouble when subjected to legal and technical scrutiny.

The fact is that the word "organic" (as used in the term organic chemistry) should have been abandoned when Berzelius' views were overthrown. Perhaps it is not too late to do this even now, drastic as such a departure will appear to the orthodox.

Difficulties, such as those revealed at the Board of Trade enquiries, will increase in the future and if precision is to be attained—and what is more important, absolute agreement amongst chemists—it can only be by the discontinuance in service of a word which is not only unscientific and misleading, but inaccurate.—I am, Sir, etc., T. W. Barber

Barrackpore, Bengal
March 27, 1923

ABSORPTION OF LEAD AND ARSENIC BY GLASS

Sir,—Referring to your report of the case against Boots Cash Chemists (Western), Ltd., at Birmingham, for selling potassium carbonate containing 10 parts of arsenic and 80 parts of lead per million, which was dismissed on April 6, I am reported as having said that in a sample of potassium carbonate placed in a similar bottle "less than 5 parts per million of *arsenic* had increased to 15 parts per million in a fortnight." Will you kindly note that what I actually said was that there was an increase from less than 5 parts to 15 parts of *lead* in this time. I find that I am correctly reported in the official shorthand notes, but other reports have apparently made an error.—I am, Sir, etc.,

THE TAXATION OF MOTOR-CAR FUELS

Sir, — The taxation of motor-car fuels seems to have again become a point of practical consideration, but the adjustment of such a tax, at so much per gallon, if it is to be fair to all the substitutes for petrol now available, has become vastly more difficult since the time when different brands of gasoline were the only fuels in use.

Other things being equal, such as the absence of injurious substances, and a sufficient volatility for the ordinary carburetter, the value of a motor-fuel is dependent entirely on its calorific value. The calorific testing of a liquid fuel is quite simple, and the gas companies are rapidly accustoming the public to understand the meaning of the Therm. If, therefore, the taxation of any fuel were based on its calorific value per gallon, no one would have any ground of complaint. If necessary the boiling point or flashpoint could also be taken into account, and the tax limited to those below a certain point, so as to exclude ordinary burning oils and heavy fuel-oils. The use of the latter for motor-cars with engines on the Diesel principle need hardly yet be taken into account, and if the absence of tax encouraged experiment in this direction, it would be very much to the public advantage. If any adjustments are desirable between commercial and private vehicles they could easily be adjusted as at present, by taxes on the vehicles themselves. I am of opinion that a fuel tax is the fairest form of motor-taxation, but it must be based on principles suited to our modern knowledge and requirements.—I am, Sir, etc.,

Henry R. Procter

Newlyn, Penzance
April 18, 1923

Sir,—Having been allowed to see the letter from Prof. Procter on the above subject, I venture to write you in reference to a matter which is of very considerable importance to your readers.

The first paragraph of Prof. Procter's letter would lead one to imagine that a proposal had been officially made that motor fuels should be subject to some form of taxation which varied according to the nature of the fuel. For some ten years motor fuel, which then consisted chiefly of petrol, was taxed at so much per gallon, a rebate being allowed to certain classes of users. As alternative fuels were then not employed to any considerable extent, and as it was thought desirable to encourage the use of home-produced fuels, alcohol and benzol were not taxed. During the last few years taxation has been levied on the vehicle. The injustice of this is obvious, and all great motoring organisations in the country and the motor industry as a whole desire a return to fuel taxation, arguing that though the amount of fuel used is not an exact measure of the damage done to the roads, nevertheless it is very closely related thereto. The main opposition to the change comes from the heavy motor-vehicle side and from certain Government Departments. That the heavy motor-vehicle users do damage out of all proportion to the tax paid is common knowledge, and their opposition is readily comprehensible. It is proposed that there should be a flat rate tax on all motor fuels, and the practicable difficulties in the carrying out of the taxation actually intended are sufficient without introducing questions as to calorific value. Neither is it correct to state that the calorific value is a real measure of the value of a motor fuel. A No. 3 spirit consisting essentially of paraffin compounds is not as good a fuel as one of lower heat value containing aromatics or naphthenes, or, indeed, containing a limited amount of alcohol, merely owing to the fact that the latter group of fuels can be used with safety at a higher compression and that the gain of thermal efficiency due to the use of higher compression far outbalances any small differences there may be in calorific value. I do not see how the flashpoint can be brought in as a qualifying factor, although it might be used merely to differentiate between a motor spirit and a kerosene. As a matter of fact, most motor spirits flash from minus 20 to minus 40° C., and in any case the flash-point can be altered to an enormous extent by the addition of almost unweighable quantities of certain bodies which dissolve in most motor fuels. I agree entirely with Prof. Procter in his opinion that a tax on motor fuel is the fairest form of taxation, but believe that any attempt to vary taxation in amount dependent upon heat value or other physical property of the fuel would be attended with unsurmountable difficulties in practice and would be against the best interest of the motoring community. The fuel of the future will probably be one of low calorific value, which will be used much more efficiently than are the present fuels of high calorific value. The fuel of the lowest heat value at present available as a motor fuel is alcohol, and this is already severely taxed owing to the fact that it has to be denatured with considerable quantities of expensive products the nature and quantity of which is determined by the Government. As alcohol is the one fuel which can be produced without calling upon stored-up natural reserves, and as it can be produced within the British Empire, every encouragement should be given to those who are endeavouring to prepare for the time when petrol is not available in quantity to meet the ever-growing demand. In any scheme of motor fuel taxation, alcohol, which is already penalised by the denaturing laws, should be left tax free, and it is very debatable whether home-produced motor benzol should not receive preferential treatment. The taxation of benzol is attended with many difficulties and will be costly out of proportion to the returns. Moreover, every encouragement should be given to the development of low-temperature distillation and to the stripping of towns' gas. The whole problem of fuel taxation is one of considerable complexity, but it should be regarded not from the narrow standpoint of the Ministry of Transport but broadly from the point of view of Nation and Empire.—I am, Sir, etc.,

W. R. Ormandy

Belsize Park, London
April 23, 1923

PERSONALIA

Lieut.-Col. G. R. Lane-Fox has appointed Prof. W. S. Boulton, D.Sc., Prof. S. M. Dixon, M.A., M.Sc., Dr. J. S. Haldane, F.R.S., Prof. C. H. Lees, D.Sc., F.R.S., and Prof. J. F. Thorpe, C.B.E., D.Sc., F.R.S., to be additional members of the Safety in Mines Research Board.

The degree of D.Sc. in biochemistry has been awarded by the University of London to Miss K. H. Coward for a thesis entitled "The Formation of Vitamin A in Plant Tissues.

Mr. H. Barringer has been elected president of the Institution of Petroleum Technologists for the ensuing session.

Dr. R. W. Whytlaw-Gray, science master at Eton, has been appointed to the Chair of Chemistry in the University of Leeds, as from October 1, in succession to Prof. A. Smithells, F.R.S.

Mr. H. S. Taylor has been appointed professor of physical chemistry in Princeton University; G. Blumrick, formerly research chemist to the Welsbach Co., has been appointed chief research chemist for the Mantle Lamp Co.; and Dr. W. C. Gangloff, formerly research chemist to the National Aniline & Chemical Co., has accepted the position of chief chemist to the Dextro Products, Inc., Buffalo, United States.

Dr. G. Morselli has succeeded Prof. G. Bruni as president of the Italian Society of Chemical Industry for 1923 and 1924, and Prof. Senator E. Patern has been elected to the seat in the Académie des Sciences left vacant by the death of the Prince of Monaco.

Prof. Lenze has been appointed Director of the *Chemisch-Technische Reichsanstalt*, Berlin; Prof. A. Holste, of the Pharmacological Institute of the University of Jena, has been appointed professor of pharmacology and director of the Pharmacological Institute of the University of Belgrade; Dr. A. Kipple has succeeded Prof. A. Koch in the Chair of Agriculture and Bacteriology in the University of Gottingen; and Prof. P. Trendelenburg has been nominated Professor of Pharmacology in the University of Freiburg.

Prof. G. Tammann, of Gottingen, has been awarded the Bakhuis-Roozeboom Medal of the Royal Academy of Sciences of Amsterdam for his researches in connexion with the Phase Rule.

* * *

With regret we announce the death, at the age of ninety, of Mr. G. Ward, a member of the firm of Hirst, Brooke and Hirst, manufacturing chemists, and chairman of the Yorkshire Section of this Society from 1900 to 1902 and also from 1912 to 1914. As teacher of chemistry at the Leeds Institute, Mr. Ward's pupils included Sir E. Brotherton, Mr. J. E. Bedford and many other well-known men.

J. D. Van der Waals, a physicist who had devoted much time to investigations on the theory of surface tension, on Boyle's Law and other topics, died recently at the age of 87 in Amsterdam.

Prof. G. Siringo, incumbent of the Chair of Chemistry at the Royal Technical Institute, Chieti, has died at the age of fifty-five.

NATIONAL UNION OF SCIENTIFIC WORKERS

A public meeting will be held by the London Branch of this Association in the Birkbeck College on May 8, at 6 p.m., and Sir R. Gregory will speak on "The Worth of Science," Mr. C. S. Garland, M.P., presiding. A cordial invitation to attend is extended to all those interested in the work of the Union.

NEWS AND NOTES

AUSTRALIA

Sugar Industry

It is reported that previous estimates of the current year's production of sugar will not be realised. The Queensland sugar crop was estimated at 300,000 tons, but it is doubtful whether production will exceed 265,000 t., and as the New South Wales output will reach 18,000 t., the returns from the sugar producing areas will total 280,000 t. The sugar content of the cane, however, has exceeded expectations, the yield averaging 1 ton of sugar to 7 tons of cane as compared with 1 t. of sugar to 8 t. of cane in the previous season. It is reported that even if the estimated production is attained, there will be a carry-over of about 10,000 t. of sugar in Australia at the end of Government control in June, 1923.—(*U.S. Comm. Rep., Mar.* 12, 1923.)

UNITED STATES

Platinum and Allied Metals in 1921

The U.S. Geological Survey announces that the domestic production of platinum in 1921 was 977 oz. Platinum refiners, however, purchased 1021 oz. of domestic platinum from which 813 oz. of refined metal was recovered as follows :—Platinum 580 oz., palladium 3 oz., iridium 99 oz., osmiridium 119 oz., and osmium 12 ounces. Purchases of foreign platinum totalled 56,645 oz., nearly all of which came from Colombia. In addition to the above sources, certain amounts of these precious metals are recovered from scrap metal, nearly 26 per cent. of the consumption being obtained in this way. In 1921, the total recovery of platinum and allied metals was :—Platinum 39,131 oz., palladium 4887 oz., and iridium 1776 oz., making a total of 45,794 oz.

Sugar Industry in 1922

According to the annual report for 1922 of the American Sugar Refining Co., the world's estimated output of cane and beet sugar during 1922-23 will amount to 17,988,925 tons as compared with 17,637,728 t. in 1921. Of this amount 12,659,635 t. represents cane sugar and 5,329,290 t. beet sugar, the totals in the previous year being 12,657,786 t. of cane and 4,979,942 t. of beet sugar. The United States production of cane and beet sugar in the current year is estimated at 1,674,875 t. (cane 1,049,875 t., beet 625,000 t), as compared with 2,061,221 t. (cane 1,150,031 t., beet 911,190 t.) last year. Imports of full-duty sugars in 1922 totalled only 47,301 t. against 198,638 t. and 885,868 t. respectively, in 1921 and 1920. The chief sources of supply in 1922 were :—Mexico, 19,623 t. ; Nicaragua, 8501 t. ; Guatemala, 4809 t. ; Honduras, 4144 t. ; Peru, 2804 t. ; and Venezuela, 2481 t. Exports of refined sugar during the same period amounted to 819,964 t. (416,881 t. in 1921, 412,494 t. in 1920), and the chief destinations included the United Kingdom, 268,275 t. ; France, 150,810 t. ; Germany, 47,528 t. ; Norway, 32,864 t. ; Greece, 32,354 t. ; Turkey, 27,212 t. ; the Netherlands, 26,044 t. ; Spain, 25,361 t. ; Belgium, 23,190 t. ; Italy, 22,316 t. ; Argentina, 21,964 t. ; Uruguay, 15,837 t. ; British India, 12,455 t. ; and Egypt, 12,218 t. Exports in 1922 went to 83 foreign countries, the amount being practically equal to the 885,868 tons imported into the United States from nearly 50 foreign countries in 1920. It is considered that the export trade could be increased to a million tons per annum without curtailing domestic requirements.—(*Bd. of Trade J., April* 5, 1923.)

Proposed Cultivation of Rubber, Camphor and Quinine in the Philippines

A measure is before the Philippine Legislature to permit the use of about 50,000 acres for the cultivation, under the Forestry Bureau, of rubber, camphor and quinine for 20 years. It is stated that after the initial investment is recovered, a forestry tax of 10 per cent. will be levied.—(*U.S. Comm. Rep., Feb.* 26, 1923.)

German Observations on the Coal Industry

A report recently published by the German National Coal Commission deals with observations made by a German engineer on the coal industry of the United States. He remarks on the extensive use of mechanical diggers and the resulting continuous increase in the daily output per worker. Formerly sorting and washing the coal were unnecessary, but with the development of less clean seams these operations are being extended. Mention is made of the importance attached to coal analyses by coke manufacturers, who improve their products by using suitable mixtures of the raw materials. In general firing practice, the desirability of using large fire-boxes is becoming recognised. Recent development in coal-dust firing are dealt with ; it is pointed out that in this method it is not so much the quantity of ash that is important as its melting point, a consideration which may lead to the development of brown coals for dust firing.

JAPAN

A New Mercury Deposit

A new vein of quicksilver said to be seven miles long and to vary in width from 2 to 6 feet has been discovered near Kita Uonome in the Goto Archipelago. The ore contains 18 per cent. of mercury and preliminary trials indicate that the vein increases in thickness with depth. This discovery is important, as none of the veins so far discovered in Japan are suitable for working, and it should make the country independent of foreign supplies.—(*U.S. Comm. Rep., Feb.* 12, 1923.)

GERMANY

Chemical Industry and the Ruhr Occupation

Dr. A. Neuburger, discussing in the *Chemiker-Zeitung* (April 5, 1923), the effect of the French occupation on chemical industry in Germany deals with the consequent necessity of obtaining foreign coal at high prices. He draws particular attention to the large quantities of fuel locally available in the form of coke contained in the slag daily turned out of the furnaces and in the vast slag heaps that have accumulated in many places. The older these slag heaps are the more fuel will be obtainable from them, since modern firing is far more efficient than in former days. Several processes are available for the separation of the coke, and an efficiency of 98–100 per cent. is attainable. The calorific value of the fuel averages about 5500 cals. Apart from the fuel question, much depends on whether the German chemical industry is able to obtain coal-tar and its countless products from new sources to take the place of that previously supplied by the Ruhr coking concerns. The indications are, however, that the chemical industry, though having to make many sacrifices, will survive the French occupation.

The Peat Industry

Not only in neighbouring States but also outside Europe the peat industry is attracting increasing attention. Not only is peat used as a fuel, but it is also distilled, coke and other products, such as tar and alcohol, being obtained. In a forthcoming special international number the German weekly, *Deutsche Torfindustrie-Zeitung* will give a review of the present condition of the world's peat industry, and it is hoped that this will initiate the interchange of ideas between experts of other countries.

Shale Bricks

The development of the extensive oil shale deposits of Germany presents many difficulties owing to the small oil content. A method has recently been proposed for utilising these shales to make a cheap building material. The shale is ground and mixed with sand or clay, the proportion depending on the richness of the shale. Bricks of the material are shaped and placed in a kiln where they are baked by the combustion of their own oil. The bricks so obtained contain only small quantities of calcium sulphate and sulphite, and are as hard as ordinary bricks, from which they differ very little in appearance.

Clinker Bricks

An interesting plant is being worked at the municipal gas-works at Würzburg. Clinker is ground, mixed with one-ninth of its weight of cement, and the mixture formed into bricks. By this means 8 cubic yards of a good building material are produced from half a cubic yard of cement, with the consumption of energy equivalent to about 13 lb. of coal. The bricks are 10 in. by 4·8 in. by 4 in., their size making them economical of mortar. Volume for volume these bricks are produced at only half the cost of ordinary bricks; they have a low heat conductivity and fireproof properties which render them suitable for building dwelling houses.

Glass Textiles

Recently a novel process has been patented by a German inventor, E. Klapp, who has developed the manufacture of fancy articles from glass wool. Glass fibres or bundles of threads are cemented to a base suitably formed from glass threads, smooth or rough surfaces, with coloured or plain patterns being obtainable. The process has been worked during the past year by the "Kristallco" Co., which has produced a series of fine articles such as lamp-shades, etc.

GENERAL

Chemical Society

The von Baeyer Memorial Lecture will be delivered by Prof. W. H. Perkin, F.R.S., in the lecture hall of the Institution of Mechanical Engineers, Storey's Gate, Westminster, on Thursday, May 10, at 8 p.m.

It is announced that the Chemical Society Research Fund Committee will meet early in June. Applications for grants should be made on forms obtainable from the Assistant Secretary, Chemical Society, Burlington House, W. 1, and must be lodged with him by June 1.

The Ordinary Scientific Meeting to be held on May 17 at 8 p.m. will be followed by an informal meeting.

The Salt Industry

Mr. W. J. Lewis lectured before the Geographical Association at Birmingham University on April 12 on the geography of Central Cheshire, with special reference to the salt industry. He said there were two layers about ninety feet thick, and it had been shown recently that the salt field extended a good deal further south than was previously thought. Making a very conservative estimate, it was probable, at the present rate of output, that the Cheshire salt field would last another thousand years. The salt trade grew steadily until the early 'eighties, after which it went down to 57 per cent. of the record output of over two million tons in 1884, and now stood at about 72 per cent. of that record. The decline was due to the development of other salt fields in the British Isles; to the competition of Central Europe, where there were pure deposits of natural rock salt; to the development in America; to the competition of tropical countries where sea salt could be produced; and, to some extent, to tariff barriers. In the early 'eighties the Cheshire industry dominated most of the world markets, but since then many of its customers had developed their own resources, and the future of the industry lay with the development of the alkali trades based upon salt.

The World's Production and Consumption of Copper

In 1913 the United States was not only the chief producer of copper, followed in order of importance by Japan, Mexico, Australia and Chile, but also the chief consumer, followed by Germany, the United Kingdom, France and Russia. Figures for post-war years are not yet available, but it appears that Chile has replaced Japan as the second largest producer, whilst the Belgian Congo has substituted Australia, and possibly exceeds Mexico as a source of copper. During 1922 Chile exported 76,000,000 lbs. of copper to the United States and Great Britain and a certain amount to other countries. The copper deposits in the Katanga region of the Belgian Congo are amongst the largest in the world. and the output has grown from 12,000,000 lbs. in 1913 to about 70,000,000 lbs. in 1921, mostly directed to England. Australian copper production has declined from 101,000,000 lbs. in 1913 to 42,000,000 lbs. in 1921 owing to labour troubles and lack of transport facilities. Exports of copper from Japan, which in pre-war years averaged 82,000,000 lbs., have declined by over three-fourths. The output of copper in smelters in the United States totalled 981,000,000 lbs. in 1922, most of the production being refined electrolytically.—(*Ch. Comm. J.*, *April* 6, 1923.)

New Paper-making Materials

Appended is an account of results of examination at the Imperial Institute of paper-making materials from various parts of the Empire.

Talipot palm-leaf stalks. Different parts of this palm (*Corypha umbraculifera*) have been put to a variety of native uses, and the leaf stalks have recently been examined as a paper-making material. It was found that the stalks are a promising material as they furnish a fairly good yield of pulp. Unbleached pulp yields a strong brown wrapping paper, and fairly white paper of good strength can be made, but the pulp bleaches with difficulty, requiring a large quantity of bleaching powder. It is therefore doubtful whether the manufacture of white paper from the stalks would be remunerative.

Betel-nut husks. Trials of pulp made from betel-nut (*Areca catechu*) husks, showed that these are not very suitable for paper making, and could only be employed in conjunction with longer fibred materials for producing low-grade brown papers or boards, but their utilisation even in this way is not very promising.

Elephant grass. Promising results were obtained some years ago in paper-making trials with samples of elephant grass (*Pennisetum purpureum*) from Uganda. Further trials of pulp from Nigeria were equally satisfactory, but exportation of the grass to the United Kingdom would not be remunerative, and it is recommended that the grass be used locally for the production of " half stuff " for export.—(*Bull. Imp. Inst.*, XX, No. 3, 1922.)

Bismuth Industry in Transbaikalia

It is reported that the Russian Trade Delegation in Germany is negotiating for the participation of foreign capital in the exploitation of bismuth mines in the Transbaikalia territory. The bismuth deposits are situated about 70 kilometres from Chita, and a railway, coal mines, and sufficient labour are available locally. Bismuth, it is stated, is extracted by a new process from the ore, the reserve of which is estimated at 1500 tons.—(*Raw Materials Rev.*)

The Artificial-Silk Industry

The artificial-silk industry continues to progress, and interesting information on this subject has been given at the annual meeting of the Société de la Soie de Tubize on March 13. During the past year this company made an agreement with the Dreyfus-Clavel group and the British Cellulose and Chemical Manufacturing Co., which will enable the former company to manufacture cellulose-acetate silk and market it in Europe. Cellulose-acetate silk has certain special qualities not possessed by other artificial silks so far manufactured. This new silk has been given the name of " célanèse " by the Tubize Co., and owing to its elasticity, fineness, insulating qualities and physical appearance, could replace for many purposes the natural product, over which it has a marked advantage in price. A factory to manufacture 500 kg. of célanèse per day is being built at Tubize, and the company has already rented a works at Grand Querilly, near Rouen, belonging to the Cie. Générale des Produits Chimiques de Normandie. This works was built during the war to manufacture cellulose acetate by the Dreyfus process. The Tubize Co. already manufactures 6000 kg. of artificial silk per day at Tubize, and an associated company at Tomazof produces over 1500 kg. per day, whilst the Tubize Artificial Silk Co. of America produces 10,000 ℔. per day at Hopewell. The demand for artificial silk continues to exceed the production, although the output is continually increasing. The Tubize Co. proposes to establish a factory to spin acetate silk at Rouen or at Lyons, but apparently does not intend to manufacture acetate silk at Grand Querilly as long as importation of the product from England is possible. Only if competition—and it seems that this could only come from the Usines du Rhône—prevents importation, will acetate silk be manufactured at Grand Querilly. The Tubize Co. is now carrying out experimental manufacture of the silk to acquire experience of the process. In addition to the factories at Lyon and Besançon, which manufacture Chardonnet silk, those at Givet, Izieux, etc., which produce cuproammonium silk, and that at Arques la Bataille which turns out viscose silk, new factories are being founded at Lyon (acetate silk), Rennes (Chardonnet silk), Strasbourg, etc.

Austrian Coal and Iron Industry in 1922

According to the Association of Austrian Mine-owners 3,130,701 tons of coal was won during 1922, as compared with 2,697,689 t. in 1921, the quantities of brown coal being 2,967,915 t. and 2,469,425 t. in the two years, respectively. A falling-off in orders followed the stabilisation of the krone, becoming more and more noticeable from October to December, though the position in Lower Austria continued to improve. A summary of the output from various areas follows :—

District	Brown coal (tons)	Hard coal (tons)
Styria	2,864,160	387
Upper Austria	425,320	2,623
Lower Austria	183,839	159,776
Burgenland	393,709	—
Carinthia	100,819	—

Iron ore production in Austria during 1922 amounted to 2,793,087 t., of which Styria and Carinthia produced 2,065,269 t. the remainder coming from Salzburg and Lower Austria. The output of pig-iron in 1922 was 322,822 t., compared with 606,655 t. in 1913.

The Occurrence and Uses of Bentonite

Bentonite, a mineral whose remarkable properties have attracted considerable attention of late, is a variety of clay which has so great an affinity for water that it will absorb more than three and up to eight times its own volume of liquid, swelling up considerably and producing a colloidal mass resembling thick starch paste. The mineral is usually hard, dull and powdery, but waxy on a freshly-cut surface, and varies in colour from yellowish-green to almost black. Like other clays bentonite consists essentially of aluminium silicate, but varies in composition, typical analyses running as follows, per cent. :—Silica, 59·84—69·52 ; alumina, 11·84—26·58 ; ferric oxide, 2·46—3·35 ; calcium oxide, nil to 2·90 ; magnesia, 0·21—2·76 ; alkalis, nil to 4·47 ; loss on ignition, 5·45—13·80. The chief known deposits of bentonite occur in North America, beds being found in Wyoming, Montana, South Dakota, California, Utah, etc. in the United States and in Alberta and British Columbia in Canada. Already the uses of bentonite are numerous, and in addition to those recorded previously in these columns (*Cf. Chem. and Ind., p.* 80, 1923), it is now stated that bentonite clays can be utilised in making ceramic products. It appears that the mineral will attain considerable commercial importance, and deposits of clay throughout the Empire should be examined to see if bentonite is present. Bentonite can be readily detected by dropping into water, when it swells and assumes the consistency of soft soap, and finally goes completely into suspension ; further, the edges of a piece of bentonite fuse readily in a blowpipe flame, whereas clay will not. The Imperial Institute requests that promising samples should be forwarded for investigation.—(*Bull. Imp. Inst.*, XX, *No.* 3, 1922.)

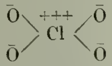
REVIEWS

The Structure of Atoms. *By* Alfred Stock. *Translated from the second German edition by* S. Sugden, M.Sc. *Pp. viii*+88. *London : Methuen and Co., Ltd.*, 1923. *Price* 6*s. net.*

Dr. Stock's little book represents the substance of a series of lectures delivered at the Farbwerken vorm. Fr. Bayer and Co. at Leverkusen in September, 1919. The fact that such a series of lectures should be given at all is remarkable ; but the author has justified fully his choice of a subject by the skill with which he has unfolded the fascinating story of recent developments in " Ultrastrukturchemie." In reading the book one constantly comes across dramatic statements such as the following : " Von Laue assumed that Röntgen rays were the same kind of vibration as common light, but of much smaller wave-length. On this view one would no more expect them to be diffracted by an ordinary spectroscope grating than one would expect to produce a spectrum from ordinary light by means of the rails of a fence." " A gram of thorianite is found to contain 9 c.c. of helium gas ; from the thorium content of this mineral it can be calculated that only $3{\cdot}7 \times 10^{-8}$ c.c. of this gas are produced annually ; hence at least 240 million years must have elapsed since this mineral was first formed." Or, " A gram of radium disintegrated completely into helium and electrons would develop 10^{11} cals., a quantity a million times that developed by the most violent chemical reaction hitherto observed. If this energy could be utilised it would form by far the most important source of power for industrial purposes."

But whilst the lectures were of a popular character, and were delivered to an audience a large part of which must have been unfamiliar even with the outlines of the subject, there are plenty of passages which will appeal by their novelty to readers who are much more sophisticated. Some of these statements challenge thought and invite comment. It is, for instance, interesting to note that " P. Pfeiffer regards crystals as compounds of very high molecular weight which have a structure in accordance with the laws of co-ordination of the well-known theory of Werner." This is the converse of the view which the reviewer has recently laid before the readers of this *Journal*, namely, that co-ordination represents at least in part the effect of crystal forces and crystal structures persisting in solution.

In view of its country of origin it is perhaps only natural that Dr. Stock's book should assign most of the credit for formulating the electronic theory of valency to Kossel. It is, however, surprising to see that, whilst Langmuir is quoted with three other authors as the creator of " later theories " which " were based on Kossel's work and have little advantage over it," the epoch-making work of G. N. Lewis, on which Langmuir's papers were based, is not even mentioned. This omission is of course necessary in order to maintain the view that the current theories of valency were *later* than Kossel's work and *based upon it*; but this is grossly untrue in the case of Lewis. A comparison of the theories of Kossel and of Lewis shows that, whilst the former is already obsolete in several points, the latter is just as valid to-day as it was when first put forward in 1916. The existence of non-polar valencies was, indeed, admitted by Kossel; but he did little more than pay lip-service to them, and worked out nearly all his formulæ on the assumption of a transfer of electrons. The result of this is a piling up of electrostatic charges that makes the formulæ quite unnecessarily complex. For instance, in the perchlorate ion, ClO'_4. Kossel assumes that the chlorine first parts with seven electrons, to form an ion which must be formulated as $Cl^{+++++++}$; the single negative charge of the ClO_4 ion is then attributed to a preponderance of one electron on the four negatively charged oxygen ions O^{--} O^{--} O^{--} O^{--}. In this case, the system of Lewis represents the chlorine atom as completing its octet by acquiring *one* electron from the hydrogen of the acid, and then sharing four duplets with the four oxygen atoms, so that the formula of the ion becomes



In the case of elements such as chlorine, oxygen and nitrogen, Kossel is obliged to admit the existence of a non-polar bond; but he assumes "that the stable ring of electrons contains, in the molecule of nitrogen 10, in that of oxygen 12, and in that of chlorine 14 electrons, which are symmetrically arranged between the two similar nuclei." The assumption that in nitrogen gas there are no electrons at all of the L-series specifically attached to either atom, but that ten of them chase one another round an intermediate orbit finds no support whatever from the physical study of the gas. For instance, "Sommerfeld has deduced from the optical properties of nitrogen that the molecule of this gas contains two nitrogen nuclei, which each carry seven positive charges. Each nucleus is surrounded by four firmly-held electrons, whilst six more loosely-bound electrons form a ring between the two nuclei and hold them together." Sommerfeld's conception is completely at variance with Kossel's structure, but differs from that of Lewis only in that the six loosely-bound electrons which hold the two nuclei together are formulated by Lewis as three duplets. Lewis' views are also in close accordance with the facts of stereochemistry, a branch of science which Kossel appears to have overlooked complctely. It appears therefore that whilst Kossel may claim with Lewis an equal share in the development of the idea of valency based on the transference of electrons, the credit for the idea of valency based on electron-sharing belongs almost exclusively to Lewis.

Dr. Stock claims that: "The lion's share in the future development of this subject will probably be appropriated by physics." "The chemist who is not at the same time a physicist, will have to stand aside and view the working out of these things with somewhat mixed feelings." He also quotes von Weinberg as saying that: "The further development of the structural problems of organic chemistry can scarcely be attempted until the problem of the fine structure of electrons in atoms has been solved." In the opinion of the reviewer the chemist will not be dismissed from his post so easily as Dr. Stock imagines. The clear enunciation of electron-sharing as a factor in chemical combination was due to a physical chemist and not to a physicist; and even at the present time physicists are still speculating as to the way in which they can best appropriate this idea and assimilate it into their scheme of quantum orbits. Even in so simple a case as that of hydrogen-gas, it is not yet clear that a satisfactory physical mechanism of electron-sharing has been developed; and there are as yet no indications that the phenomena of stereochemistry are within the grasp of the physicist even in so simple a case as that of methane. Dr. Stock admits, perhaps a little reluctantly, that "chemistry should really go hand in hand with physics in the working out of these problems"; but this is actually the only way in which the wide gap which now separates the theories of the physicist from the facts of the chemist can be bridged. The contribution of the chemist towards the bridging of this gap is to bring together a bewildering array of phenomena, and to group them in such a way that they can be understood and appreciated by the physicist. Thus the real value of phrases such as "unsaturation," "conjugation" and "co-ordination," is that each of them summarises a vast collection of detailed experimental facts. The share of the physicist is to devise a mechanism by which these phenomena may be referred to a common origin based upon a theory of the structure of the atom; but in this work the physicist is not necessarily superior to the chemist, any more than an office boy is necessarily superior to a mechanic because he handles words rather than things.

The work of translation has been very well done by Mr. Sugden, but a few errors remain to be corrected in a subsequent edition, *e.g.*, on page 33 Planck's constant is confused with the quantum itself; on page 49 there is an obvious inaccuracy in the equations $232{\cdot}18 - 32{\cdot}00 = 206{\cdot}18$ and $225{\cdot}96 - 20{\cdot}00 = 206{\cdot}07$; and on page 80 the formulæ for sulphuric and perchloric acids have slipped into error. It is also an eyesore to see Bunsen spelt with a small "b."

It is unfortunate that four years have elapsed between the delivery of the lectures and the appearance of this translation. This has prevented the introduction of Bragg's complete system of Ångström units, which forms so valuable an aid to the study of atomic and molecular magnitudes; it also accounts for the omission of Bohr's table of quantum orbits, which the reader naturally expects to see in a book dealing with the structure of atoms and published in 1923. There must, however, be many readers who will find pleasure in this popular account of modern theories; and the style in which the book is issued contributes a share to the attractiveness of the volume.

T. M. LOWRY

(1) DIE LUFTSTICKSTOFF-INDUSTRIE. *By* Dr. BRUNO WAESER. *Pp. vii*+586. *Leipzig: Otto Spamer*, 1922. *Price, including export tax*, 42,000 *marks*.

(2) THE NITROGEN INDUSTRY. *By* Dr. J. R. PARTINGTON *and* Dr. L. H. PARKER. *Pp. xv*+336. *London: Constable and Co., Ltd.*, 1922. *Price* 21*s*.

(1) This substantial German treatise by Dr. Waeser forms one of a series on monographs on chemical technology edited by Professor Binz, of Berlin. Its compilation was commenced before the war, when the synthetic-nitrogen industry was quite in its infancy. The information it contains is said to have been obtained in part directly from a number of leaders of German chemical industry, but much has evidently been culled from technical papers.

The work is divided into three main sections: first, introductory and general; second, historical and economic; third, technical. It has not been possible to read the whole volume critically, but from a general perusal it is evident that while the treatise is one which should in some respects be of considerable value, a certain amount of the information it contains is quite unreliable, and has evidently been derived in a number of instances from the claims made for projects which never came to fruition, rather than from records of actual fact. Nevertheless the book contains a good deal of quite useful material, especially as regards German developments. For example, the section dealing with the Haber-Bosch synthetic-ammonia process, although giving less information about the actual manufacturing operations than Messrs. Partington and Parker's volume, includes many details as to the products made at the factories of the Badische Anilin und Soda Fabrik Company at Oppau and Merseburg. It is interesting to note that at both works the gypsum process for fixation of ammonia as sulphate is now employed on quite a large scale, thus obviating the necessity for large quantities of sulphuric acid, now a relatively expensive product, needing for its manufacture, imported sulphur or pyrites. The necessary gypsum is obtained from the company's own deposits in the Hartz Mountains. The different fertiliser products made by this company, including the now notorious ammonium nitro-sulphate, which was the cause of the Oppau explosion, are fully described.

A good feature of the book is that in most cases references are given, and it is obvious that a very large number of patent specifications has also been consulted. On the whole, the work is uncritical, and care does not appear to have been taken to differentiate sufficiently between processes which are obsolescent or already obsolete, and those which are at the present moment of great technical importance.

(2) The important work by Prof. Partington and Dr. Parker is much smaller, but more readable than the German treatise. It bears the impress of a thorough acquaintance with the subjects discussed, and, in contrast with the German work, which in general is not critical, does not hesitate to criticise many of the processes and statements under review.

Part I gives a general introduction to the nitrogen problem, and discusses the extraction and refining of Chile nitrate in considerable detail. Part II comprises a review of the by-product ammonia and ammonium-sulphate industry, whilst Part III, divided into four sections, deals mainly with the synthetic ammonia, cyanamide and arc processes, and the oxidation of ammonia.

Throughout the whole volume extensive use is made of the work of the Nitrogen Products Committee, and many of the tables and statistics, given in the Report of the Committee and in the Statistical Supplement to the same compiled by the writer are reproduced and discussed. In the Committee's Report attention was chiefly devoted to the general, statistical, and financial aspects of the different nitrogen-fixation processes, great stress being laid throughout on factors of cost, both of the capital expenditure involved and the cost of production of the different products. In the present work, however, more detailed descriptions are given of the processes themselves, and illustrations are added depicting various items of plant employed; mention should be made of the excellent plates, giving views of some of the more important nitrogen-fixation factories of the world. The volume may be regarded as bearing the same sort of relation to the Nitrogen Products Committee's Report as Mr. and Mrs. Sidney Webb's Commentary to the famous Minority Report on the Poor Law. Many people seem to have a prejudice against blue-books of any kind, and to these the volume will certainly make a special appeal.

Section (1), describing the synthetic-ammonia process, and consisting of about forty pages, is less detailed than some other parts of the book, although good descriptions are given of the German plants. One of the most interesting features of this chapter is a short history of the developments of the process in England, France and America. *Section* (2), also of about forty pages and dealing with the cyanamide process, is more complete, but the information given is mainly statistical, rather than practical. *Section* (3) is devoted to the arc process. Of special interest are the first few pages summarising the history of this process. Due credit is given to the late Lord Rayleigh for the pioneering work he accomplished in measuring for the first time the relation between the energy expended and the amount of nitrogen fixed. It is a somewhat astonishing fact that even in the largest and most successful modern plants, employing furnaces of 4000 kw. capacity, the increase in the yield obtained per kw. expended, over that given by Lord Rayleigh's primitive apparatus does not exceed 50 per cent. *Section* (4), on the oxidation of ammonia, is one of the best in the book. This was rather to be expected, since it was with this particular division of the work of the Nitrogen Products Committee's Research Laboratory that the authors were at one time associated. Descriptions are given of the various forms of converter employed, as well as details of their operation. Although a considerable amount of interest was taken in England in the oxidation process during the war period, present day statistics of importation indicate that the country's comparatively modest peace-time requirements of ammonium nitrate (necessary for manufacture of blasting explosives) are now being obtained from abroad, all the ammonium-nitrate works which operated during the war having apparently been dismantled.

An unusual feature, not often to be met with in a technical work of this character, is that the authors do not hesitate to discuss and criticise most severely the ineffectiveness of British Government policy and comparative lack of actual achievement in nitrogen matters. In some respects their outspokenness is justified, but a certain number of their statements are not in accord with the facts.

We have been accustomed to hear some of those, who are pleased to think themselves chemical engineers, deride so-called " academic " chemistry, and scoff at " laboratory " experiments, as distinct from those carried out on a works scale. It is, therefore, perhaps not surprising that occasionally the " pure " chemist engaged in research should don his armour, enter the lists and joyfully seize his opportunity of having a fling back. We find scattered throughout this book from the preface onwards, quite a number of instances where the authors digress to preach the value of abstract research, and to rub in the sentiments expressed in Davy's somewhat extravagant jibe of a hundred years ago that " the chemical manufacturer has rarely discovered anything ; he has merely applied what the philosopher has made known."

J. A. Harker

Fuels, Gas, Water and Lubricants. *By* S. W. Parr. *Pp.* 250. *London: McGraw-Hill Publishing Co.*, 1923. *Price* 12*s.* 6*d.*

The author of this book is Professor of Applied Chemistry at the University of Illinois. He points out that the work, which is in its third edition, is the result of over 10 years' effort to arrange a chemical course intended primarily for mechanical and railroad engineers in their junior year. It is admitted in the third edition that something has been added to render the work more likely to be of value to junior students in chemical engineering. Although the title of the book is very comprehensive the subjects treated at length are coal, gas and water, and these are looked at very strictly from the industrial point of view. Those portions of the book dealing with other than the abovementioned subjects only amount to a dozen pages or thereabouts.

The work is divided into two sections, the first dealing in a general manner with the subject and the second giving details for the laboratory examination of the products dealt with. In the first section it is interesting to note that a complete chapter is devoted to the important subject of sampling. A good deal of space is devoted to the consideration of expression of results and the important subject of the drawing-up of coal contracts is discussed in a separate chapter. The methods of analysis employed are for the most part those recommended by the American Society for Testing Materials, and this applies particularly to coal and oil analyses. As is customary in American books, practically all the references contained in the work are to American literature. Although all tabular matter and analyses refer to American coal and American waters, this reduces the value of the work for European students in comparatively small degree, since the points which it is thought to emphasise are of general applicability. The sections on coal and boiler-water are excellent and many interesting tables of analytical data are given relating to the classification of American coals. There is also a number of tables contrasting waters from various sources in the United States, including some which are naturally alkaline.

The author mentions the difficulty of finding sufficient time in the crowded course of an engineering student to deal adequately with the important subjects treated, and refers to the limitations of chemical knowledge when the student commences that particular course. The book is of undoubted value to the engineering student and the practical bearing of all the technical work is so brought into prominence that chemical students about to enter a works laboratory would find much profit from its perusal. As is customary with books published by the McGraw-Hill Co., the work is well got up and adequately indexed.

W. R. Ormandy

THE ORIGIN OF SPECTRA. *By* P. D. FOOTE *and* F. L. MOHLER. *American Chemical Society: Monograph Series. Pp.* 250. *New York: The Chemical Catalog Co., Inc.* 1922.

This book is another of the valuable monographs now being published by the American Chemical Society as the outcome of the Inter-Allied Conference for Pure and Applied Chemistry held in 1919. The authors state that it was their intention to discuss the quantum theory chiefly from the experimental point of view, but to do this they were obliged to discuss the theory itself. This is fortunate, as it enables the inexperienced reader to follow the lucid descriptions more easily. The book is divided into eleven sections: Quantum Theory of Spectroscopy; Energy Diagrams; Ionisation and Resonance Potentials for the Elements; Line Absorption-Spectra of Atoms; Line Emission-Spectra of Atoms; Cumulative Ionisation; Thermal Excitation; Thermochemical Relations; X-Rays; Photo-electric Effect in Vapours; and Determinations of h Involving Line Spectra. In the Appendix there are given Computational Data, Periodic Tables, and Bohr's Theory of Atomic Structure. It is impossible to give a detailed account of the work owing to its concentration, but the authors discuss the work of Bohr, Sommerfeld, Stark and Zeeman, and give preference to the theory of Bohr over that of Langmuir as being more in accordance with spectroscopic phenomena. Excellent illustrations of spectra are given in addition to clearly reproduced drawings and diagrams. The volume appears to the reviewer to be a model of concentration, and it should be indispensable for every student in the field of spectroscopy. H. E. FIERZ

DIE ERDOLLAGERSTÄTTEN: GRUNDLAGEN DER PETROLEUMGEOLOGIE. *By* DR. E. BLUMER. *Pp. xv+*442. *Stuttgart: F. Enke*, 1922. *Price* 12*s*. 6*d*.

This book, by the well-known petroleum geologist Dr. E. Blumer, is the result of many years of experience, and represents the first attempt to summarise the known facts of the geology of petroleum in a way that will appeal to the expert as well as to the non-technical reader. The book, admirably printed and illustrated, is strikingly different from the usual scientific treatises in being written with a clarity and precision rivalling that of A. von Humbolt's "Cosmos." According to the author, petroleum is of purely oceanic origin, and is still being formed in enormous quantities, and attention is drawn to the deplorable waste which is now going on. The book will appeal to many who are not specially interested in geology, and it is not only valuable from the purely scientific point of view, but is also refreshingly original in these dull and prosaic times.

H. E. FIERZ

OUTLINES OF THEORETICAL CHEMISTRY. *By* DR. F. H. GETMAN. *Third edition. Pp. xi* +625. *New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.*, 1922. *Price* 18*s*. 6*d*.

The domain of physical chemistry is becoming so large that it is not easy for the writer of a text-book to cover the ground within a reasonable number of pages. Thanks to a concise and lucid style, Dr. Getman has succeeded in doing so without sacrifice of clarity or interest. All the usual branches of physical and electrochemistry are adequately treated, and in addition are included up-to-date chapters on colloids, the electrical theory of matter, radioactivity and atomic structure. The treatment of electromotive force and of photochemistry is especially good, and the periodic classification of the elements is dealt with in a short but illuminating chapter.

As stated in the preface, "with the exception of a few paragraphs in which the application of the calculus is unavoidable, no use is made of the higher mathematics"; where Dr. Getman has (most rightly) felt constrained to employ the calculus, the exposition is so clear that the mathematical facility required for its comprehension should be within the reach of every Honours student. A number of good numerical problems is appended to most of the chapters.

The elementary principles of thermodynamics including derivations of the Clapeyron-Clausius and Gibbs-Helmholtz equations, are dealt with in 19 pages, and here the reviewer feels that brevity has been overdone. Students almost invariably find it difficult to grasp the principles of thermodynamics, but easy to apply them once they are throughly understood, and a more ample discussion of the fundamentals of the subject would have been welcome.

A few misleading statements have been noticed. The statement that ". . . when the external work, resulting from a change in volume, is not included in the heat of reaction, the process is said to take place at constant volume" might be misunderstood. Hess's law of constant heat summation is stated and applied without qualification, whereas it is only valid for reactions taking place at constant volume or at constant pressure. In the statement of the phase rule, the term "independent variables" is applied to the components of a system; it more properly related to the degree of freedom. The velocity constant of a multimolecular reaction does not depend on the initial concentration, as implied; it is the time required for the completion of a given fractional change that varies in the manner stated.

The diagrams are clear and well chosen; the indexing, printing and general arrangement are good. The book is to be highly recommended, both for private reading and as a class text-book.

D. C. HENRY

COMPANY NEWS

THE UNITED PREMIER OIL AND CAKE CO., LTD.

At the annual meeting held on March 27, Mr. H. Guedalla, who presided, said that business prospects were improving, costs of production decreasing, and there was a good chance of regaining the export trade. During the past year the debenture stock had been reduced by £9,900, leaving £384,350 outstanding. The reserve fund stood at £54,508 after writing off a loss of £10,147 incurred in selling an investment in a margarine company, which had not been successful. It was decided to pay a dividend of 5 per cent., less income-tax, out of the net balance of £48,174, leaving £20,517 to be carried forward.

THE ELECTRO-BLEACH AND BY-PRODUCTS, LTD.

At the annual meeting held in Manchester on March 21, it was decided to pay dividends of 5½ per cent. (making 9 per cent. for the year) on the preference shares, and of 18 per cent. on the ordinary shares, absorbing a total of £29,000; £14,116 was transferred to reserve, and £1,244 carried forward. The total profit made in 1922 amounted to £51,281. The issued share capital of the company comprises £200,000 preference shares, and £100,000 ordinary shares.

THE UNITED GLASS-BOTTLE MANUFACTURERS, LTD.

After providing for depreciation, income-tax and debenture interest, the profit during 1922 was £37,867 (compared with a loss of £139,713 in 1921); including a credit of £29,077 the available balance was £66,944, the stock reserve £12,500, and the carry forward £54,444. Owing to the general conditions of the trade, the directors did not feel justified in recommending resumption of payments of dividends on preference shares at present.

THE UNITED ALKALI CO., LTD.

The accounts for the period January 1, 1921, to December 31, 1922, show a total net profit of £578,214. After transferring £30,000 to debenture redemption and £76,991 to reserve the sum of £156,695 is brought into the accounts and a dividend is to be paid of 2s. per share on the ordinary shares, less tax. Owing to a change in the methods of manufacture at the North American Chemical Co.'s works, part of the plant has been sold for £273,009, which has been carried to reserve. It is proposed to capitalise £300,000, part of the undivided surplus, and allot it to ordinary shareholders at the rate of one share for every two ordinary shares, thus reducing the carry-forward to £86,735. It is also proposed to increase the capital of the company to £4,500,000 by creating 900,000 new ordinary shares of £1 each, and to sub-divide the 300,000 preference shares of £10 each into 3,000,000 of £1 each.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Nauru Phosphates

Sir R. Sanders, replying to Mr. Blundell, said that experiments with phosphates from Nauru and Ocean Islands were in progress, but results of the trials were not yet available. During the 2½ years ended December 31 last, the import of phosphate from Nauru and Ocean Islands was about one-tenth of the amount to which the United Kingdom was entitled under its agreement with Australia and New Zealand.—(Apr. 16.)

Exports of Milk Powder

In reply to Mr. H. Simpson, Viscount Wolmer said that the export of milk powder of home manufacture in 1922 was 51 tons, valued at £5602; the re-exports of milk powder of foreign and colonial manufacture during the same period totalled 545·5 t. valued at £36,052.—(Apr. 17.)

Exports of Coke and Pig Iron

Answering Mr. J. Davison, Viscount Wolmer said that during, 1922 1,602,671 tons of coke (other than gas coke), 651,212 t. of pig iron and 142,704 t. of ferro-alloys were exported, compared with 902,666 t., 462,175 t., and 117,334 t., respectively, in 1920.—(Apr. 17.)

Replying to Mr. Hardie, Viscount Wolmer said that the export of metallurgical coke during the first quarter of 1923 was 489,237 t., an amount actually less than in the last quarter of 1922 by over 2000 t. per week.—(Apr. 18.)

Non-ferrous Metal Industry

In a written answer to Mr. Hancock, Lieut.-Col. Lane-Fox stated that the number of lead mines closed since the war was 52 and of tin mines 55, representing a loss of employment for 1000 and 3282 persons respectively.—(Apr. 17.)

Smoke Abatement

Mr. Chamberlain informed Sir W. Sugden that any possible assistance would be given to individual firms desiring to limit the output of black smoke. The local Council, however, was the smoke authority and to it application should be made.—(Apr. 18.)

Disinfectants

In a written answer, Mr. Chamberlain informed Mr. Becker that he had no evidence to show that disinfectants devoid of bactericidal action were being sold to the public, but he was aware that disinfectants differed considerably in their bactericidal power. He could not adopt the suggestion that disinfectants for sale should comply with a test. Advice as to choice of disinfectants for particular purposes could generally be obtained from local health offices.—(Apr. 18.)

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for April* 19)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia	Tinplate, steel, brass, copper plates	498
Belgium	Lead and copper ingots	505
Brazil	Tin, tinplate, linseed oil, soap, perfumery	526
British West Indies	Cement	499
Canada	Drug specialities, proprietary medicines	501
"	Cut glass	*
Colombia	Paint, varnish	527
Czecho-slovakia	Toilet soap	507
Denmark	Oilseed, linseed, cottonseed	508
"	Brass sheets	509
"	Pickled and close annealed sheets	7315/F.R./E.C./2
Egypt	Paper (tender)	**
Italy	Anhydrous sodium sulphate	510
"	Metals and alloys	512
Netherlands and Netherlands East Indies	Corrugated iron	517
New Zealand	Gas mantles, lighting glassware	503
Rumania	Copper sulphate (tender)	10486/F.E./C.C./2
Switzerland	Hardware and ironmongery	522
United States	Fertilisers, palm, palm kernel and coconut oils, copra	524
" "	Scientific apparatus	10891/E.D./C.C./2
" "	Cement	19237/F.W./M.C./2

* Canadian Government Trade Commissioner, 73, Basinghall Street, E.C.2.

** Sudan/Stores/Reg./39-2. Inspecting Engineer, Egyptian Government, Queen Anne's Chambers, S.W.1.

TARIFF CUSTOMS EXCISE

Bolivia.—Exports of silver have been made dutiable at rates to be fixed according to the price of silver on the London market.

Esthonia.—The exportation and transit of precious metals, etc. has been prohibited, except under a special permit.

Germany (*Occupied*).—The statistical tax will be levied on foreign goods imported into the Occupied Territories. The issue for April 19 gives information concerning the treatment of imported and exported samples.

Mexico.—The export tax on copper has been reimposed. On chilte an export duty of 50 cts. per 100 kg. (gross weight) has been imposed.

Poland.—The duty on sugar is increased from 60,000 to 150,000 Polish marks per 100 kg. net, and on petroleum from 50 to 150 Polish marks per kg. net. Exports of copper, nickel, cadmium, brass, German silver, Britannia metal and all other metal alloys in shavings, splinters and cuttings, have been prohibited, but the exportation of mineral, sperm and cylinder oil is permitted.

Portugal.—Further information regarding the new customs tariff is given in the issue for April 19.

Roumania.—In the April 19 issue a list is given, showing certain modifications in the import and export duties. The list includes cement and sulphate of iron.

Siam.—A law has been passed restricting the importation of habit-forming drugs.

REPORT

Report on the Economic and Financial Conditions in the British West Indies, June, 1922. *By* A. W. H. Hall, *Officer-in-Charge, H.M. Trade Commissioner's Office, Trinidad. Department of Overseas Trade. Pp.* 32. *H.M. Stationery Office,* 1922. *Price* 1s. 0*d.*

In most of the West Indian colonies sugar is by far the most important industry, and duties on sugar and its products provide a large proportion of the revenues, but the future of the industry is uncertain and, especially in Jamaica and British Guiana, unless a bigger demand arises within the British Empire, production will fall (*cf.* J., 1922, 266 r). The prospects of cocoa planters are not considered hopeful, and though Trinidad, the chief producer, exported 432,674 cwt. during the period January-June, 1921, the following crop was disappointing and only 300,219 cwt. was exported in the same period of 1922. The output of petroleum in Trinidad in 1921, 82,395,595 galls., surpassed the previous record, 72,905,907 galls., in 1920. There are now 607 oil wells in Trinidad (*cf.* J., 1922, 402 r). It has been proposed to cater for the large cement trade by the erection of a factory in Jamaica and possibly also one in Trinidad (*cf. Chem. and Ind.*, 1923, 20).

The total value of imports into Jamaica in 1921 was £5,473,790 (of which the United Kingdom supplied 29·3 and the United States 54·6 per cent.), compared with £10,313,282 in 1920 (U.K. 29·7%, U.S. 58·6%). Detailed statistics are not given, but in 1920 the imports were very varied. Exports (not valued) included sugar, 28,729 tons; rum, 958,758 gallons; copra, 1,570,262 lbs.; logwood, 4,512 t.; logwood extract, 6,951 packages (*cf.* J. 1922, 132 R).

In 1921, Trinidad imported goods to the value of £6,905,694 (U.K. 25·0, U.S. 35·6%), compared with £8,376,912 in 1920 (U.K. 26·5, U.S. 41·5%), including:—Cement, £67,933; chemicals, £22,292; manures, £43,034; coal, £199,149; glass, china, etc., £45,879; paints and colours, £22,838; soap, £75,173. Exports included sugar, 46,695 t.; rum, 162,423 galls.; copra, 4,163,103 lbs.; petroleum, 39,315,828 galls.; asphalt, 93,318 t.

Imports into Barbadoes totalled £2,642,273 in 1921 (U.K. 35·9, U.S. 22·2, Canada 22·5%), against £5,145,537 in 1920 (U.K. 30·3, U.S. 35·7%). The chief export was sugar, 26,344 t.

British Guiana imported in 1921 goods valued at £3,239,471 (U.K. 46·4, U.S. 25·1%), against £4,722,709 in 1920 (U.K. 41·3, U.S. 33·3%). Exports consisted chiefly of sugar, 108,270 t., and rum, 2,228,164 galls.

These figures show that British trade is not unsatisfactory in the West Indies; apart from the preferential rates of duty which operate in favour of goods from the United Kingdom and Canada there is a genuine desire to obtain British articles where possible. Although competition with the United States must in some lines be regarded as almost hopeless, it would be possible with some little effort to capture others from American merchants, *e.g.*, soaps, boot and other polishes, and painters' colours and materials, including turpentine substitutes.

THE SUGAR BEET INDUSTRY

At the eighth annual meeting of the British Sugar Beet Growers' Society, Ltd., the chairman, Mr. G. H. Roberts, reviewed the sugar market, and said that it was doubtful if the duty on sugar was reduced whether the consumer in this country would get any advantage as American speculators might be able to force up the price. In presenting the Mason Cup for sugar-beet growing to Mr. T. Hardy, of Peterborough, for a yield of 18 tons 6 cwt. per acre with an average sugar content of 15·4 per cent., Mr. Roberts said that these figures did not indicate the average yield for the whole sugar-producing area; the average of the Kelham and Cantley companies, for instance, varied from 8 to 11 tons per acre. At the luncheon Sir F. Floud described the steps which led to the building of the Kelham beet sugar factory, and said that the movement deserved support because it was of such great assistance in helping to maintain the arable area of this country. The Ministry anticipated a great increase in beet growing, and beet could be grown equal in quality to any in the world.

MARKET REPORT

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The market for heavy chemicals continues good, and in many cases where there is evidence of short supply there is a tendency for prices to harden. Stock Exchange quotations are the soundest indicators of the trade position, and as such they point to a continuation of the recent improvement in chemicals generally.

Acid Acetic 40% tech.	£23-£25 per ton. No change in position.
Acid Hydrochloric	4s.-5s. per carboy d/d.
Acid Nitric	£24 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Still in good demand.
Alumina, Sulphate of	It is reported that British makers' prices are now competing with those ex the Continent, and trade is, therefore, better.
Arsenic (White)	£70-£75 per ton. Not much trade passing.
Bisulphite of Lime	£7 per ton. Packages extra.
Bleaching Powder	£10 10s. per ton d/d. In slightly better request.
Calcium Chloride	£6 per ton d/d.
Copper Sulphate	£27 per ton. Somewhat firmer.
Potash Caustic	£35 per ton. Position still firm, with limited supply.
Potassium Bichromate	5¾d.-6d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.-£5 per ton. Considerably firmer, with no very large quantity on offer.
Soda Caustic, 76%	£20-£21 per ton. Continues in good demand.
Sod. Acetate, 97/98%	£26 per ton.
Sod. Bicarbonate	£10 10s. per ton.
Soda Crystals	£5 10s. per ton. No change.
Sod. Bisulphite Powder, 60/62%	£19-£20 10s. per ton, according to quantity.
Sod. Chlorate	3d. per lb. Small inquiry.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, conc.	£16 per ton, carr. paid. A considerably better market.
Sod. Sulphite, Pea Cryst.	£17-£17 10s. per ton, according to quantity.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£26-£28 per ton, according to quantity.

Carbon black	1s. 5½d. per lb. ex wharf. Supplies very scarce—production in U.S.A. falls very short of demand.
Chromium Oxide	1s. 5d. per lb.
India Rubber substitutes, white and dark	5½d.-6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£10 15s. per ton d/d.
Grey	£20 5s. per ton d/d.
Liquor	9d. per gall., 32° Tw.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall., 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 10s. per ton d/d.
Brown Sugar of Lead	£40 per ton d/d.

The prices of wood distillation products have advanced slightly, and a fairly good demand has been maintained.

TAR PRODUCTS

Acid Carbolic, Crystals	1s. 6d. per lb. Makers fully sold for prompt delivery. Slightly lower prices are quoted for forward delivery.
crude 60's	3s. 6d.-3s. 9d. per gall. Not much enquiry.
Acid Cresylic, 97/99	2s. 2d.-2s. 5d. per gall. Good demand.
Pale 95%	2s.-2s. 4d. per gall Market firm.
Dark	1s. 10d.-2s. 0½d. per gall. Market firm.
Anthracene Paste, 40%	4d. per unit per cwt. Price nominal. No business.
Anthracene Oil—	
Strained	9½d.-11d. per gall. Numerous enquiries.
Unstrained	9d. gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8½d. per gall.
Pure	2s.-2s. 2d. per gall.
Toluole—90%	1s. 9d.-2s. per gall.
Pure	2s. 2d.-2s. 6d. per gall.
Xylol	2s. 9d.-3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	11d.-1s. 1d. per gall. Not much inquiry.
Middle Oil	8¾d.-10¼d. per gall. Market fairly steady.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d.-9¼d. per gall.
Solvent 90/160	1s. 7d.-1s. 9d. per gall. Fair business doing.
Solvent 90/190	1s. 6½d.-1s. 8d. per gall.
Naphthalene, Crude—	
Drained Creosote Salts	£7-£9 per ton. More inquiry.
Whizzed or hot pressed	£11-£14 per ton. Market firm and active.
Naphthalene, Crystals	£17 10s. per ton.
Naphthalene, Flaked	£16 10s. per ton.
Pitch, Medium Soft	180s.-200s. per ton. Price nominal. Little inquiry for this season.
Pyridine—90/140	11s.-12s. 6d. per gall.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

There is very little change in the position with regard to Aniline Dyestuffs during the present week. Orders have been just a little freer and there is a tendency on the part of consumers to look a little further ahead and buy in rather larger quantities than they have done in the past. Buyers seem to have regained some of the confidence in trade generally as there seems to be more tendency to inquire for contracts for forward delivery than there has been for some time.

There is no tendency whatever for prices to be reduced; in fact, prices are very firm, with an upward tendency in one or two specialities.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhydrous	1s. per lb. d/d.
Aniline Oil and Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlor Phenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	Fair demand with advanced prices in sympathy with Carbolic prices.
m-Cresol 98/100%	2s. 3d. per lb. Fair demand.
p-Cresol 32/34° C.	2s. 3d. per lb. Fair demand.
p-Dichlor Benzol	£70 per ton.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene—	
48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d. Packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
α-Naphthol	2s 9d. per lb.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d.-8d. per lb.
Nitronaphthalene	1s. per lb. d/d.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s 6d. lb. 100% basis d/d.

R Salt	3s. 3d. per lb. 100% basis d/d.
Sod. Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid Acetic 80%	£52 10s. per ton.
Acid Acetyl Salicylic	3s. 2d.-3s. 6d. per lb. Best makes advanced and strongly held.
Acid Benzoic	2s. 3d. per lb. Remains steady.
Acid Citric	1s. 8½d.-1s. 9d. per lb., less 5% for ton lots. Dearer. Demand good and improving. Higher prices probable.
Acid Gallic	3s. per lb. for 2-cwt. lots, 3s. 3d. per lb. for 56lb. lots.
Acid Pyrogallic, cryst.	5s. 9d. per lb.
Acid Salicylic	2s. 2d.-2s. 6d. per lb. Any increase in demand would, it is thought, result in higher prices being quoted.
Acid Tannic	3s. 3d. per lb.
Acid Tartaric	1s. 4d. per lb., less 5%. In addition to the increased demand for the home trade, there is much enquiry from the Continent and the U.S.A. consequent upon the failure of supplies from Germany. Italian manufacturers are understood to be booked up with orders well ahead, having sold largely in the U.S.A., so that supplies from that market in appreciable quantities are not to be looked for here. Raw materials continue to advance, so that a further rise in the price of Acid is anticipated.
Amidol	9s. per lb.
Acetanilide	1s. 8d. per lb. Much firmer. Spot supplies much smaller.
Amidopyrin	13s. 6d. per lb. Still little demand at this figure.
Ammon. Benzoate	3s. 9d. per lb.
Ammon. Carbonate B.P.	£37 10s. per ton.
Barbitone	18s. per lb. Firmly held at this figure.
Benzaldehyde	3s. per lb.
Bismuth Salts	Unchanged.
Bromides	Still very firm. Ammon. 10d. per lb., Potass. 8d. per lb., Sod. 9d. per lb.
Calcium Lactate	2s. 9d. per lb.
Chloral Hydrate	4s. per lb. Unchanged.
Hexamine	4s. 6d. per lb. with higher prices looked for in the near future.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots.
Magnesium Carbonate, Light Commercial	£38 per ton.
Magnesium Oxide, Light Commercial	£85 per ton.
Menthol	31s. per lb. original cases. Smaller quantities 32s. per lb. nett.
Methyl Salicylate	2s. 8d. per lb. for carboys is the advanced rate.
Methyl Sulphonal	14s. 6d. per lb., showing no change in value.
Mercurials	Market somewhat easier owing to drop in price of mercury.
Paraldehyde	1s. 7d. per lb. Stocks more firmly held at this price.
Phenacetin	6s. 6d. per lb. Without prospect of immediate reduction.
Phenazone	7s. 6d. per lb. still wanted.
Phenolphthalein	5s. 6d. per lb. Firmer.
Potass. Bitartrate—99/100% (Cream of Tartar)	95s.-98s. per cwt. Dearer, but price has not advanced in correspondence with that of the raw material.
Potass. Iodide	15s. 8d. per lb. in cwt. lots. Good steady demand.
Potass. Permanganate	10½d.-11d. per lb. No supplies are now available under this quotation.
Potass. Sulphoguaiacolate	5s. per lb. quoted, being a low value.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. Steady demand.
Resorcin	5s. 9d. per lb. Slightly firmer.
Salol	2s. 9d. per lb. Some holders want 3s. per lb.
Saccharin	Slightly better demand.
Sod. Benzoate	2s. 3d. per lb. No alteration has been made, though an advance in price is expected.
Sod. Citrate	U.S.P. quality 2s. 2d. per lb. for cwt. lots. Rather quiet.
Sod. Hyposulphite—Photographic	£15-£17 per ton.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d. per cwt. Poor demand.
Sod. Salicylate	Advanced for best makes to 2s. 9d. for Powder, 2s. 11d. per lb. for Crystal. Lower prices from 2s. 4d.-2s. 6d. per lb. quoted in some quarters.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. per ton f.o.r., London, 1-cwt. wooden kegs included.
Sulphonal	14s. per lb.
Tartar, Emetic	1s. 4d. per lb.
Thymol	18s. per lb. for good White Crystal still quoted, though a lower price would probably be accepted for a large quantity.

Prices for all pharmaceutical chemicals are well maintained and the general position is much steadier in view of slightly increased demand both for home and export consumption.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil, Red Ship Brand	2s. 1d. per lb.
Bergamot Oil	12s. 6d. spot, 13s. 6d. forward.
Cananga Oil, Java	9s. per lb.
Cassia Oil 80/85%	8s. 3d. per lb.
Cinnamon Oil, Leaf	4¼d. per oz.
Citronella Oil—	
Java 85/90%	4s. 3d. per lb.
Ceylon	3s. 3d. per lb.
Clove Oil	8s.-8s. 6d. per lb.
Eucalyptus Oil 70/75%	1s. 9d. per lb.
Lavender Oil, Mont Blanc, 38/40%	13s. per lb.
Lemon Oil, Spot	3s. 1d. per lb. Higher prices are asked for forward delivery.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet, Spot	11s. 6d. per lb.
Otto of Rose Oil—	
Anatolian	24s. per oz.
Bulgarian	30s. per oz.
Palma Rosa Oil	17s. per lb.
Peppermint Oil—	
English, Mitcham	80s. per lb.
Wayne County	13s. per lb.
Japanese	6s. 3d. per lb.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	2s. 6d. ,, ,,
Amyl Butyrate	8s. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (melting point 21/22° C.)	4s. 3d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	3s. ,, ,,
Benzyl Benzoate	3s. ,, ,,
Cinnamic Aldehyde—	
98/100% Natural	14s. 9d. ,, ,,
Coumarin	15s. 6d. ,, ,,
Citronellol	22s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	18s. 6d. ,, ,,
Ethyl Phthalate	4s. 3d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palma Rosa)	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	7s. 6d. per lb.
Iso Eugenol	16s. 6d. per lb.
Linalol, ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	22s. 6d. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Ketone	35s. ,, ,,
Musk Xylol	9s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	24s. per lb. Better demand.

TRADE NOTES

German Chemical Trade in 1922

The following table gives particulars of exports from Germany in 1922 of a few important chemical products:—

	Metric tons				
Destination	Coal-tar dyes	bronze colours	Lithopone	Ammonium nitrate	Potassium nitrate
Great Britain	468	124	—	2,677	3,584
Belgium	143	50	655	685	—
Denmark	175	—	—	—	—
Italy	1,339	69	494	—	1,189
Netherlands	1,010	34	918	689	349
Austria	1,195	—	831	1,029	256
Czechoslovakia	3,035	—	—	765	—
Sweden	625	—	—	313	—
Switzerland	504	—	—	—	159
Spain	950	—	—	—	579
British India	2,608	—	—	—	—
China	8,924	—	—	—	—
Japan	3,798	—	—	—	955
United States	206	469	3,244	9,036	—
Total to all countries	36,011	1,162	11,043	19,892	12,117
Value in millions of paper marks	26,173	1,075	1,280	4,260	1,290

In 1913, 64,288 t. of coal tar dyestuffs, valued at 164 millions of gold marks, was exported, 1016 t. going to Great Britain and 13,855 t. to the United States; this shows how much the demands in these markets have fallen. Before the war Great Britain and France were large buyers of lithopone, but here again the demand has fallen off. Potassium nitrate was exported in 1913 to the extent of 16,058 t., valued at 6,985,000 gold marks. Great Britain then, as now, was the largest buyer, taking 7516 t.

Prices of Chemicals in Germany, 1922

The following table shows how the index figure representing chemical prices changed in the last quarter of 1922, and offers a comparison with those for industrial materials, wholesale trade prices, and the value of the dollar. Each figure shows the ratio of the price in point to the corresponding price in 1913.

Month	Chemicals	Industrial materials	Wholesale trade	Dollar
October	531·7	569·4	566·0	757·7
November	1167·9	1307·8	1151·0	1711·1
December	1893·9	2060·7	1474·8	1807·8

German Potash Industry

Sales of German potash were estimated in 1922 to about 1,300,000 tons of pure potash (K_2O), a record figure, that for 1921 being 900,000 t. In December prices were increased by about 58 per cent. and this, together with enormously increased costs of transport, caused a diminution in home sales during January and February.

The Russian Chemical Industry, 1922

The following particulars are given in a recently published Soviet report on the chemical industry, relating to 12 out of a total of 17 factories:—

	1922	
	July	August
Average number of workers	3,576	3,663
Working days performed (1000's)	81·5	1,059
Working days missed (1000's)	28·0	6·1
Production of important commodities:—	Tons	
Sulphuric acid	1,378	1,231
Hydrochloric acid, commercial	798	643
Saltcake	576	514
Bisulphate	212	235
Soda ash	—	1,446
Caustic soda	—	603

Chemical Trade of the United States in 1922

Only three groups of exports from the United States showed increases in 1922. "Chemicals and Allied Products" was one group, and although the gain was but 1·4 per cent. this must be contrasted with decreases ranging from 8 to 31 per cent. for other groups. Chemical products constitute one of the smaller groups of the United States' exports, their value being only 2·8 per cent. of the total for 1922. Under chemical products, however, are included dyestuffs—a new industry—and paints and varnishes, an industry which has faced abnormal conditions for some time. The value of the total exports of chemicals was $106,101,562, compared with $104,639,941 in 1921, the increase being due to gains of 50 per cent. made by explosives, 33 per cent. made by perfumery, etc., 11 per cent. by medicinal and pharmaceutical preparations, and 3 per cent. by fertilisers. Exports of pigments, paint and varnish made a good recovery from the stagnation prevailing early in the year, the total being only 5 per cent. less than in 1921, but exports of general chemicals were 4 per cent. below the level of 1921. Statistics of the exports of chemicals in 1921 and 1922 are given below:—

	1921		1922	
	lb.	$	lb.	$
Copper sulphate	3,582,933	217,491	5,250,556	256,432
Acetate of lime	18,239,740	404,528	27,596,106	591,599
Bleaching powder	18,447,579	483,752	41,069,188	679,775
Glycerin	2,394,714	361,507	2,870,463	425,891
Potassium chlorate	375,401	49,709	562,986	51,066
Sodium silicate	20,789,095	247,761	29,131,925	302,511
Sal soda	10,354,513	204,616	11,463,418	186,284
Sodium bicarbonate	11,703,183	307,138	15,853,945	341,385
Caustic soda	49,865,219	2,041,236	146,739,406	5,271,528
Calcium carbide	11,808,252	606,999	12,835,916	633,297
Soda ash	35,042,791	850,369	29,627,574	678,983
Formaldehyde	(1)	349,089	1,940,577	209,386
Ammonia and ammonium compounds (other than ammonium sulphate)	(1)	(1)	7,247,480	990,111
Aluminum sulphate	(1)	(1)	26,450,857	388,447
Acetic acid	(1)	(1)	5,080,519	367,717
Boric acid	(1)	(1)	1,968,996	197,265
Borax	4,061,633	269,771	17,242,571	867,417
Sulphuric acid	12,814,344	317,720	12,470,389	201,267
Medicinal and pharmaceutical preparations	—	12,724,430	—	14,193,065
Crude drugs, essential oils, dyeing and tanning materials	—	5,888,577	—	6,451,422
Peppermint oils	—	—	128,606	298,743
Essential oils	—	—	—	585,072
Logwood extract	—	589,756	—	448,713
Dye extracts	—	1,203,155	—	459,861
Explosives	10,433,830	2,285,849	19,212,449	3.400,391
Dynamite	9,567,442	1,815,999	14,105,017	2,406,398
Mineral earth pigments	—	—	27,631,228	981,905
Lithopone	—	—	3,231,722	169,982
Enamel paints	—	—	1,501,520	418,521
Red lead and litharge	1.095,173	115,500	3,366,375	294,133
White lead	10,321,415	993,130	9,196,656	710,765
Paints, stains, etc.	—	6.490,414	—	4,908,013
Linseed oil	3,512,228	406,460	2,702,634	332,781
	Gallons		Gallons	
Varnish	—	—	775,095	1,271,088
	Tons.		Tons.	
Phosphate rock	182,594	2,592,541	202,300	2,548,587
Land pebble phosphate	544,425	4,627,875	512,777	3,269,179
Other phosphate rock	6,293	99,721	4,217	40,401
Superphosphates (acid phosphate)	4,278	96,303	24,373	360,402
Ammonium sulphate	102,614	6,098,406	147,331	8,736,611
Calcium cyanamide	—	—	2,556	26,112
Nitrogenous materials	—	—	1,576	78,047
Prepared fertiliser mixtures	—	—	14,416	690,972
Bone phosphates	—	—	273	15,095
Other fertilisers	—	—	25,189	882,966

The total value of rubber exports was $33,450,832, a gain of $3,242,877. Coal exports declined from 2,652,827 tons valued at $12,257,038 in 1921 to 11,083,112 tons valued at $65,891,740 in 1922; but exports of coke increased from 273,888 tons ($2,760,939) to 456,733 tons ($43,195,383).—(*U.S. Comm. Rep., Feb.* 12, 1923.)

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, MAY 4, 1923 No. 18

EDITORIAL

THE Swiss Legation asks us to notice Mr. R. Hofmann's book, *Interdépendance*, published by Librairie G. Oudin, Paris, price 9 francs. Although not dealing particularly with chemistry, the subject of his book, how to achieve a prosperous Europe, is of considerable consequence to the inhabitants of this country, whether chemists or not. The book is pleasantly written, and the majority of the arguments are unanswerable. Mr. Hofmann shows very clearly how dependent all the countries of Europe are on each other, and how duties, reparations and restrictions of all kinds interfere with that easy flow of trade which is necessary to the well-being of Europe. The book appears at a time when the French occupation of the Ruhr has introduced a formidable complication, and there is no doubt that this occupation is the prime obstacle at the moment to international progress. If all the nations of Europe made the prosperity of the Continent their prime interest, Mr. Hofmann's solution would be very satisfactory. It seems to us that the British, the Swiss and the Scandinavians all wish to see Europe prosperous so soon as possible, but is this statement true of Europe generally ? Do the Russians wish for a prosperous Russia or a prosperous Europe ? Do the Turks and the Greeks let the prosperity of these countries play a very important part in their plans ? Does France wish to see Germany as prosperous as she was before the war, and, if so, when ? Do the Germans desire a prosperous France ? Who can give an answer to these questions ? Whether the French should trust their future to the benevolence of Germany is a problem which is very easy to state and to which it is very easy for everyone of us to hazard an answer. Probably the less we know of the facts, the more certain we shall be that our opinion is right, but these difficulties stand in the way of the adoption of any scheme which depends on mutual good will, mutual trade and the removal of the barriers which cross Europe in all directions. A correspondent who has just returned from the occupied zone in Germany tells us that the greater number of factories have ceased to work, having no outlet for their goods beyond the demand of the local population. It is the opinion of the German industrialists that the occupation by the French will continue for a long period, and active steps are being taken to transfer their works to other areas, amongst others to the Magdeburg district, where brown coal is available. More than one chemical factory, in addition to Krupps, is stated to be making this move ; it is significant of past prosperity as well as of present enterprise that the losses involved in such a transfer can be faced with equanimity. We commend Mr. Hofmann's book as a careful and moderate statement of the economic conditions necessary for the encouragement of international trade. Few people in this country will dispute them, but the process of the restoration of international trade in this disturbed continent will be slow, and not until Germany and France can come to a reasonable understanding will it be possible to translate Mr. Hofmann's doctrines into actual practice. It may be that France has too much at stake to find any advice useful at the moment, and it is not clear yet that Germany is imbued with such a feeling of kindliness and good will to all her late enemies that she cares, at present, to face the situation in a way which is essential for the benefit of Europe.

* * *

In our columns of to-day there appears an advertisement announcing that the Government have decided to dispose of their interests in the series of patents taken out during the war period for processes and inventions worked out by members of the staff of the Research Laboratory of the Nitrogen Products Committee. Some of these were originally secret patents, but we believe that all have now been published. It is understood that the list in question includes about 25 separate inventions for which completed patents have been granted in Great Britain, and that for the same subject matter, a very considerable number of foreign and colonial patents have either been granted or are on the way, but are not yet completed.

The inventions fall into four main groups, the first being those relating to the synthesis of ammonia as worked out mainly by the late Dr. Harold Greenwood. Among these may be mentioned the basic patent whereby by use of high circulation velocity, very large yields of ammonia could be obtained from a given quantity of catalyst, and the output of a given apparatus could be increased very much beyond that obtained in the original German process. A second relates to a cyclic method of removal of ammonia from the circulating gases, and a third to the type of catalyst bomb evolved ultimately from which the large yields previously mentioned were obtained.

The second group relates to the oxidation of ammonia and the manufacture of nitric acid and nitrates, and embodies several interesting new processes, some of which have been tried out on a semi-technical scale. Among these may be mentioned a process for the production of nitrates free from nitrites, by the direct absorption in alkalis of oxides of nitrogen; also a method for the direct synthesis of solid ammonium nitrate free from nitrite by bringing together gaseous ammonia, nitrogen peroxide, steam and oxygen. A third invention of this group is a process for the oxidation of ammonia by means of enriched air, or oxygen, in which the danger of explosion is obviated by using steam as a diluent to take the place of nitrogen. This steam is removed in a simple manner, and by this method a very high efficiency may be reached, using a very small tower system, and the by-product oxygen of a nitrogen fixation factory, may be satisfactorily utilised. In the third group, comprising inventions dealing with the preparation and purification of hydrogen and other gases, may be mentioned a promising catalytic method for sulphur removal, and also a process for the purification of hydrogen from carbon monoxide, by which this latter gas may be reduced in two-stage working to the very small concentration necessary in the manufacture of synthetic ammonia. The miscellaneous section includes two different forms of detector for indicating the presence of water vapour or either of its gaseous constituents in gaseous mixtures, and also an improved method for the production of nitric oxide by the Häusser bomb explosion process. We understand that when the Government factory at Billingham-on-Tees was sold to Messrs. Brunner Mond and Co., this company obtained a non-exclusive licence to use all these patents and that now the Government are desirous of disposing of their rights subject to this licence.

REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

Every year it becomes more and more difficult for the scientific worker to keep abreast of the increasingly large output of scientific literature and, through lack of opportunity, he has, only too often, to neglect subjects with which he is not especially concerned. Such forced neglect is all the more unfortunate in that it means a loss of the valuable stimulus derived from the consideration of problems which, although belonging to some other branch of technology, yet may contain the germ of a philosophical principle of general applicability. The JOURNAL of the Society of Chemical Industry, with its ample index, certainly provides a complete and concise directory to current technical chemical literature, but the worker who desires to obtain a general idea of progress in some branch other than his own, can do so only at the expense of much time and labour. It was for this reason that the Society of Chemical Industry, recognising the need for some general guide to the literature of chemical technology, undertook to issue the Annual Reports of the Progress of Applied Chemistry, the seventh volume of which, covering the year 1922, is now being published.

This volume, edited, like the previous ones, by Mr. T. F. Burton, B.Sc., contains 24 articles covering the whole range of applied chemistry, each article being written by an expert, who provides a critical review of the year's literature relating to his own subject and indicates, not only what progress has been made, but often the lines on which progress is desirable. Such a unique conspectus of the various activities in applied chemistry is certainly primarily of interest to the technician, but the volume will prove of value to engineers desirous of obtaining information about chemical plant and constructional materials, to biologists who require information on vitamins, enzymes, and the recognition of plant products, to industrialists wishing to ascertain the position of various industries, and to many others; and it should certainly be read by all those who are interested in the progress of the chemical industry, an industry whose well-being is so intimately associated with our national prosperity.

Although no startling discoveries may have been made during the past year, yet a perusal of the whole volume leaves a gratifying impression of the sound and steady development throughout chemical industry. Space is not available for more than a rapid consideration of the reports, but it may be of interest to indicate a few of the topics of more general interest.

In the section on "Plant and Machinery," Mr. W. H. Coleman discusses the all-important process of heating and cooling and draws attention to the remarkable development in machinery for extremely fine grinding, a subject which is also referred to in the sections on paints and pigments, cellulose, sugars, and fertilisers.

Corrosion, treated by Mr. Coleman, finds mention on many other pages, and the presentation of the different aspects of this crucial problem of to-day will be found of much interest. A valuable feature of the Reports is that subjects are often discussed from different view-points by different authors, and this is exemplified in the chapter on "Fuel," by Prof. J. W. Cobb and Mr. H. J. Hodsman, the subject of the utilisation of fuel being treated to some extent in many other sections. Smoke abatement receives due attention, and householders will no doubt benefit from the information on the efficiency of domestic heating appliances and from the accusation that our smoke nuisance is essentially of domestic origin. With the cause, the remedy—low-temperature carbonisation and smokeless fuels—is also presented. Coal receives further consideration in the section on "Gas—Destructive Distillation," in which Dr. G. Weyman shows the importance of the "combustibility" of fuel and relates recent work concerning this aspect of the fuel problem. The much-debated questions connected with the supply of town gas are discussed and some space is devoted to peat, the utilisation of which still presents so many fascinating problems. The petroleum industry is dealt with by Mr. J. E. Hackford, the section including notes on the origin, nomenclature, and treatment of petroleum and on the progress made in the evolution of substitute motor fuels.

In view of the importance attaching to the establishment of the dyestuffs industry in this country, the account of "Colouring Matters and Dyes," by Mr. E. A. Bearder, possesses particular interest, especially as dyes are finding new applications as photographic sensitisers and desensitisers and even seem likely to attain importance as bactericidal agents; dyes are discussed from this point of view in the sections on photography and sanitation. "Fibres, Textiles, Cellulose and Paper," by Mr. F. L. Barrett, is a section that shows how much more general the application of science to industrial problems is becoming. Many methods of testing fibres find mention, as well as improved methods of treating yarns and fabrics, and the problems of the constitution and properties of cellulose and its products receive full discussion. Under the heading "Wood" an account is given of recent work on the chemistry of the lignins, and of various methods of producing wood pulp, and "Paper" includes subjects such as raw materials, sizing, etc. The section on "Bleaching, Dyeing, Printing and Finishing," by Mr. W. Harrison, M.Sc., contains an interesting account of the various aspects of mercerisation, but many will no doubt turn to the description of processes for dyeing cellulose acetate silk, a problem now apparently solved.

"Acids, Alkalis, Salts" are dealt with by Mr. H. J. Bailey, who provides a valuable summary of the present position of the industrial fixation of nitrogen, discussing each process separately. In this, as in other sections, the Safeguarding of Industries Act, the industrial treatment of fumes and dusty gases are considered, and attention is drawn to Prof. J. W. Hinchley's important paper on "Evaporation."

Dr. M. W. Travers, in the section on "Glass," notes that the output of scientific work from the Department of Glass Technology in the University of Sheffield does not diminish; indeed, as in other years, the bulk of the work on questions such as durability, appears to be done in this country. In "Ceramics and Building Materials," Mr. W. Emery records progress in the investigation of the nature of the clay molecule and describes various improvements in firing technique and in kilns; refractories and building materials also come under this section.

The effect of the industrial depression and the consequent need for economical working is well illustrated in Prof. C. O. Bannister's account of "Iron and Steel," a heading which naturally includes the subject of corrosion. The section on "Non-Ferrous Metals," by Dr. C. A. Edwards and H. I. Coe, illustrates the ever-increasing importance of froth flotation and of electrometallurgical methods of treatment. Of particular interest in the portion on "Alloys" is the description of alloys of aluminium. Recent advances in the "Electro-chemical and Electrometallurgical Industries" are recorded by Dr. J. N. Pring, whose account of the electrothermal treatment of various ores, steel alloys, etc., is of considerable interest.

A valuable review of the vegetable-oil industry is provided in the chapter on "Oils, Fats and Waxes," by Mr. John Allan, who treats of subjects ranging from the synthesis of fatty acids and the reactions involved in the drying of oils, to the properties of marine-animal oils and hardened fats. Drying oils are also included in the section on "Paints, Pigments, Varnishes and Resins," by Dr. R. S. Morrell, who discusses the theory of catalysis from the standpoint of the mechanism of the drying of vegetable oils and describes recent work on the constitution of the resins. The pages devoted to paints and varnishes further illustrate the growing application of science to industry.

As might be expected, Mr. B. D. W. Luff, in the section on "India-rubber," directs attention to the situation of the rubber growers and writes at length of the industrial possibilities of the latest development of the industry, viz., the use of rubber latex in making paper, adhesives, etc.; accelerators, rubber analysis and testing are also dealt with. In the section on "Leather and Glue," Mr. D. Woodroffe comments on the depressed state of the leather industry and records recent developments in leather machinery and the progress made in the scientific control of soaking, liming, and bating processes, due reference being made to the interesting results obtained by Dr. Pickard and his co-workers; the vexed question of the analysis of tanning materials is reviewed. The importance of fine-grinding, referred to by many other contributors, is brought forward by Mr. H. J. Page, who, in "Soils and Fertilisers," discusses the effect of finely grinding phosphatic fertilisers on their availability to the plant. Those interested in nitrogen fixation will find, in this section, a discussion of the subject from the agricultural point of view, and an account is also given of progress in preparing artificial organic manure from straw and in the agricultural utilisation of activated sludge.

Mr. J. P. Ogilvie, in "Sugars, Starches and Gums," points out the importance in sugar manufacture of eliminating colloidal matter in the sugar juice and discusses the various filtration devices suggested for attaining this end. The beet-sugar industry, so new to this country, is considered at length, and an account is given of the technical applications of decolorising carbons. The general economic depression is again met in the "Fermentation Industries," dealt with by Mr. H. Lloyd Hind, whose contribution contains interesting accounts of advances in brewery practice, and a full discussion of various enzymes, yeast, vitamins, and of cellulose fermentation. The section on "Foods," by Dr. G. W. Monier-Williams, is dominated to some extent by the recent work on vitamins and on food-poisoning due to canned foods, and under "Sanitation and Water Purification," Dr. H. T. Calvert deals at length with the activated sludge process of sewage treatment and its modification, the bio-flocculation process, as well as with the disposal of various forms of solid town's refuse.

The chief advance recorded by Dr. H. King, in the section on "Fine Chemicals, Medicinal Substances and Essential Oils," is the preparation of a pancreatic extract containing the hormone "insulin," but reference is also made to valuable researches on the constitution of the alkaloids and of the sesquiterpene group, which lies between the perfume-bearing terpenes and the polyterpenes, exemplified by rubber and cholesterol. Of interest is the suggestion to use acetylene as an anæsthetic, and dyes are discussed in the light of their bactericidal action.

The phenomenal expansion of kinematography is discussed in "Photography," by Mr. R. E. Crowther, who describes developments in the use of sensitisers and desensitisers, and work on the theory of development, and concludes by pointing out that when photographic products can be produced with the regularity and certainty that characterise other chemical industries enormous expansion in the application of photography may be safely prophesied.

From this rapid review of the reports some idea may be gained of their wide scope, and it is to be hoped that all those who have realised their utility will assist in "broadcasting" their value so that they may be utilised to the fullest extent, and justify the labour expended in preparing them.

THE EXISTENCE OF AMMONIUM HYDROXIDE IN SOLUTION

By PROFESSOR R. M. CAVEN

Professor T. S. Moore, in an article on "The Existence of Ammonium Hydroxide in Solution" (*Chemistry and Industry*, 1923, p. 343) criticises some conclusions of mine in a paper on "The Basic Strength of Ammonia and Allied Bases" (*Chemistry and Industry*, 1923, p. 164). I wish to reply to his criticisms.

1. With regard to the relation between the di-hydrated double salts of the type $CuSO_4$, M_2SO_4, $2H_2O$. Since the cæsium double salt, when heated freely in the air is shown to lose water sensibly at a lower temperature than the other alkali double salts (Caven and Ferguson, *Chem. Soc. Trans.*, 1922, **121**, 1407), Professor Moore assumes that its vapour pressure, measured when it is in equilibrium with the anhydrous salt, will be greater than that of the other salts under similar conditions. This by no means follows, as is shown by experiments by Mr. Ferguson and myself recorded in the same place. Thus when the two salts $CuSO_4$, $(NH_4)_2$,SO_4, $6H_2O$ and $CuSO_4$, Rb_2SO_4, $6H_2O$ were compared it was found that whilst the former salt rapidly lost water at 42°, the latter could be heated to 55° before perceptible loss began, although the vapour pressure curve of the rubidium salt was found to lie above that of the ammonium salt throughout its whole length. So the rubidium double salt possesses a greater power of resistance to thermal dissociation than the corresponding ammonium salt, and dehydration in is consequence delayed. Therefore no conclusion regarding vapour pressure can be drawn from the exceptionally low temperature at which the salt $CuSO_4$, Cs_2SO_4, $2H_2O$ loses water; and, moreover, comparative measurements of the vapour pressures of the di-hydrates have not yet been made. So the argument which Professor Moore quotes from the paper from Mr. Ferguson and myself is not invalidated by his objection.

2. The position of ammonium in the series of the alkali metals has been established firmly by the laborious researches of Dr. Tutton, and the conclusion reached by him requires no support from me; but the work on vapour pressures differs from that of Tutton in providing a thermodynamic argument, and numerical values for the relative affinities of the basic radicles concerned. It is a satisfaction, however, to know that our conclusions have been welcomed and endorsed by Dr. Tutton (*Chem. Soc. Ann. Reports*, 1922, p. 260).

With regard to Professor Moore's work on the nature of a dilute aqueous solution of ammonia, which I regret to say I had overlooked, I accept his experimental results, but I do not draw his conclusions from them.

Let it be granted that a N/100 solution of ammonia contains 51 per cent. of this substance as an equimolecular compound of ammonia and water. On what grounds does Professor Moore assert that this is ionisable ammonium hydroxide ? Before a compound can be said to be ionisable in the usual sense there must be evidence of progressive ionisation under conditions progressively favourable to this process. Is there any such evidence ? If a larger proportion than 4 per cent. NH_3 exists as ammonium ions in a more highly diluted solution, it cannot be affirmed that these ions have been formed by the ionisation of NH_4OH, for there is an alternative process by which they may have been formed. In respect of this alternative ammonia and its derivatives are unique amongst the bases.

Why does this large proportion of a non-ionised compound of ammonia and water exist in dilute ammonia solution ? What hinders ionisation ? The view expounded in my former article, to which I still adhere, is that it is the presence of the elements of water in combination which is the hindering cause ; and that this is why only the tetra-alkylated ammonium hydroxides reveal a basic strength comparable with that of the alkali-metal hydroxides. It is of secondary importance whether the compound Professor Moore has shown to exist in solution is formulated as NH_4OH or $NH_3{\cdot}H_2O$; though I prefer the latter formulation because it better expresses the fact of non-ionisation.

Moreover, if $[H_2O{\cdot}H_2O]$ exists, why not $[H_2O{\cdot}NH_3]$? for H_2O and NH_3 are interchangeable in amines and some crystallohydrates.

Professor Moore's argument in the last sentence of his article that ammonium hydroxide is a weak base appears to be founded upon the ratio of the concentration of the non-ionised compound to that of the ammonium ion, and to ignore all other evidence of the strength of the ammonium radicle. According to this argument there would be no question of ammonium competing with the alkali metals in basigenic power ; it would be hopelessly outclassed. Yet it does not require the work of Tutton nor that upon vapour pressures to show that ammonium must take its place somewhere amongst the alkali metals. This fact, and at the same time my own point of view, are well expressed in the following words of Holleman ("A Textbook of Inorganic Chemistry," Eng. Edn., 1916, p. 335) :—

"The great tendency of ammonium hydroxide to break up into ammonia and water is the reason for the very feebly basic reaction of an aqueous solution of ammonia, for we should expect ammonium hydroxide, so far as it is formed, to be extensively ionised, like strong bases, inasmuch as the ammonium salts of strong acids, such as the chloride and the nitrate, react neutral, and the carbonate and the cyanide react alkaline, in harmony with the similar reactions of the corresponding salts of the alkali metals."

Royal Technical College,
Glasgow

FORTHCOMING EVENTS

May 4. SOCIETY OF CHEMICAL INDUSTRY, Chemical Engineering Group, Engineers' Club, Coventry Street, W. 1, at 6.30 p.m. Annual General Meeting, followed by an Informal Dinner at 7.30 p.m., and later by a Social Evening. Members of the Group may introduce non-members to the Dinner and subsequent proceedings.

May 4. UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 5 p.m. "Some Scientific Principles of Chemical Industry," by William Macnab, F.I.C. Also on May 11 and 18.

May 4. INSTITUTION OF CIVIL ENGINEERS, Great George Street, S.W. 1. "The Interdependence of Abstract Science and Engineering," by Sir R. T. Glazebrook, K.C.B., F.R.S., at 6 p.m.

May 4. THE SOCIETY OF CHEMICAL INDUSTRY, *Manchester Section*, The Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. (1) "Reflections on Patents," by H. Cheetham. (2) "The Melting-Point of Coal Ash," by Messrs. F. S. Sinnatt and A. B. Owles, and N. Simpkin. (3) "The Behaviour of the Principal Celluloses Towards Iodine and Dyestuffs," by Messrs. J. Huebner and J. N. Sinha.

May 7. THE SOCIETY OF ENGINEERS. Ordinary Meeting at The Geological Society, Burlington House, W. 1, at 5.30 p.m. "The Pneumatic Handling of Petrol and Other Inflammable Liquids," by Pierre Mauclère.

May 7. SOCIETY OF CHEMICAL INDUSTRY, *Yorkshire Section*. Annual General Meeting at the Queen's Hotel, Leeds, at 7.15 p.m. "The Adulteration of Olive Oil," by F. W. Richardson, F.I.C.

May 7. SOCIETY OF CHEMICAL INDUSTRY, *London Section*. Annual Meeting at Engineers' Club, Coventry Street, W., at 8 p.m. Sir F. Nathan, K.B.E., will open a Discussion on "The Action of Bacteria on Cellulose Materials."

May 7. ROYAL SOCIETY OF ARTS (Howard Lecture), at 8 p.m. "The Development of the Steam Turbine," by S. S. Cook (Lecture 2).

May 7. INSTITUTION OF RUBBER INDUSTRY, Engineers' Club, Coventry Street, Piccadilly, W. 1. "The Use of Rubber Products as Dielectrics," by W. S. Flight, A.M.I.E.E.

May 8. INSTITUTION OF PETROLEUM TECHNOLOGISTS. Seventy-first General Meeting at the Royal Society of Arts, John Street, Adelphi, W.C. 2, at 5.30 p.m. "Heavy Grade Egyptian Crude Petroleum," by W. A. Guthrie, F.I.C.

May 9. THE UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 5.15 p.m. "Phases of Indian Geology," by Hon. Sir Thomas H. Holland, F.R.S. Also on May 23 and 30.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

Reading Tilden's "Famous Chemists" the other evening, I came across a paragraph which had some bearing on the present controversy with regard to the title "Chemist." Tilden tells us that Liebig, after visiting England, complained in a letter to Berzelius, which he wrote in 1837, that in England "die Chemiker schämen sich Chemiker zu heissen, weil die Apotheker, welche verachtet sind, diesen Namen an sich gezogen haben." A curious observation to be made by Liebig, that, the despised apothecaries having appropriated the title, the chemists were ashamed to call themselves "chemists." A lot of water has flowed under London Bridge since then, but human nature has remained much the same. I still think that a Conference between the Chemists and the Pharmacists would hasten the time when the word "pharmacist" will become so well known to the public that we shall hear no more of this controversy.

The Correspondence Columns of this paper last week were certainly the most interesting we have had since it became a weekly newspaper. Mr. Kingzett's letter, commenting on what I said a few weeks ago, made me look up some old records which I have collected from time to time, and I can confirm what he says. Both Mr. Kingzett and the late Michael Carteighe were original subscribers to the Institute of Chemistry, and were, I believe, members of its first Council. I was always told in my young days that there would have been no trouble between the Institute and the Pharmaceutical Society but for the interference of some of the Government Departments. This is not an invitation to my readers to point out how unchanging and unchanged our rulers are.

One of Our Big Industrialists, who returned from Germany last Saturday, gave me the most recent news, and as he is a very competent observer, I have no hesitation in quoting them. Before he went over I told him of a report which was current to the effect that the Ruhr district was stocked with chemicals which the Germans were unable to get out. On his return he tells me that this is only true to a very limited extent. Firms with factories both within and without the Ruhr have closed those within and transferred the staffs to those without the district, which are being operated to their fullest extent. The output of the factories outside the area, together with the stocks in Hamburg, accumulated prior to the French occupation, and now rapidly diminishing, just about supply the German chemical market. There is at the moment, therefore, an opportunity for this country to export chemicals to the Continent for consumption chiefly in Germany.

Will Our Manufacturers Act Quickly? It seems to me that if this news is correct, and I am quite ready to believe it is, they must do so. Of two things, one: either the French occupation of the Ruhr will come to an end soon, and the German factories within the area will be re-started; or, it will continue, and the Germans will proceed to develop their factories outside the area. In either case, by a manipulation of the exchange and the free use of the printing press, we should again be placed in an unfavourable position. That is why it seems to me that at once this commercial opportunity ought to be seized.

Reading of the Scenes at Wembley reminded me to make some enquiries as to the progress being made with the Chemical Section of the Exhibition. I hear that a definite space of about 37,000 square feet has been secured in the great Industrial Hall, and I should not be surprised to learn that this is in the best position in the hall. This space is practically all earmarked for about ninety firms, although no actual sites have been allotted to individual firms. The Science Section within this space is gradually taking shape with an absence of friction which is very gratifying. An eminent architect is to be engaged to prepare plans which, while leaving ample room for individuality within the section, will make a most attractive scheme of colour and design for the section as a whole.

The Supply of Fine Chemicals made in this country continues to grow, and the latest list of fine and research chemicals issued by the British Drug Houses, Ltd., is a stupendous one. Many of these are doubtless sold as an ordinary piece of business, but there must be a great many of them which are required so seldom and by so few people that their manufacture is a pure piece of public spirit, occasioned by the desire to help British chemists to obtain reagents so as to help on the achievements of pure science. Pure chemistry has done much for the industry, and it is very pleasant to find manufacturers with so nice a sense of gratitude as this instance affords. Not only is the list very full, but it is also well printed and conveniently arranged.

NEWS FROM THE SECTIONS

NOTTINGHAM SECTION

At a meeting held on April 25 the result of the election of officers for the ensuing year was announced as follows :—Chairman : J. M. Wilkie. Vice-chairmen : S. F. Burford, H. D. Richmond. Hon. Treasurer : S. J. Pentecost. Hon. Secretary : E. B. R. Prideaux. Committee :—T. H. Adams, W. T. T. Ainsworth, L. Archbutt, H. Calam, J. B. Firth, G. F. Hardcastle, F. S. Kipping, J. Marshall, W. P. Skertchly, S. R. Trotman, J. T. Wood, and W. Woodhouse. The Annual Report and Treasurer's Report were read, and a vote of thanks was passed to the College Council for granting facilities for the holding of meetings in the College buildings.

The first paper, by Dr. J. B. Firth and Mr. J. Higson, dealt with the reactions which occur when cupric chloride is treated with sodium hyposulphite at various concentrations and at various temperatures. The reaction took place in an atmosphere of carbon dioxide, and the precipitates, after washing and drying in such a way as to avoid oxidation or decomposition, were analysed. At the lower temperatures and hyposulphite concentrations, the precipitate was essentially cuprous chloride. At the higher concentrations of hyposulphite at 15° C., and at all concentrations from 30° upwards, considerable quantities of sulphur were present. In a certain range of concentrations at 15° the precipitate was chiefly copper, with no chlorine and only a little sulphur. The compounds present were cuprous chloride, cuprous sulphide, cupric sulphide, as well as metallic copper, which was highly pyrophoric. The production of these compounds was explained and the principal equations given.

In answer to questions by Mr. H. Droop Richmond, Dr. Prideaux and Mr. Wilkie, the authors stated that the very reactive copper interacted with colloidal sulphur to give sulphide. Variable mixtures of cuprous chloride and sulphide were obtained by slight variations in the conditions.

The second paper, by Dr. J. B. Firth, on " The Absorption Activity of Carbon," gave an account of investigations carried out with a view to (*a*) the production of a highly reactive carbon, or (*b*) increasing the activity of a moderately active carbon or reactivating one which had deteriorated. In industry, the wood or other carbonaceous substance was mixed with milk of lime, or soluble chlorides or sulphates before carbonisation. In the experiments conducted by the Royal Society recently the effect of salts of lime was investigated. The product of the first carbonisation was extracted with acid, and again heated, giving a highly active charcoal. Some experiments were described in which sugar charcoal was activated by simple heating, or by heating after activation by the introduction of zinc chloride in the preliminary carbonisation. The activities were determined by titrating the iodine absorbed from a solution of iodine in dry chloroform. They were found to be considerably improved by heat treatment and by previous admixture with zinc chloride and also with kieselguhr. The catalytic activities in the decomposition of hydrogen peroxide were also investigated, and found to be in the same order as those exhibited in the sorption of iodine. The activity decayed considerably after a course of years. Theories concerning the activation and deactivation were put forward, namely, that the activity was closely associated with the molecular complexity of the carbon ; the greater this was, the less the force available for sorption. Replying to various questions the author said that the sorptive activity for iodine did not give much information as to the activity in absorbing gases. Coconut charcoal was effective for the latter, ineffective for the former. It had been shown by Henry long ago that hard woods gave an effective charcoal. A bulky charcoal such as was produced in a magnesium nitrate ignition showed a slightly higher sorption in the first five minutes. Experiments were in progress which might furnish a reply to Mr. Higson's question on the relation between the activity of a carbon and the complexity of the organic compound from which it was derived. Carbon derived from the action of iron on carbon dioxide was fairly active.

Mr. Richmond then gave an account of a remarkable case of corrosion of a glass bottle by potassium carbonate stored in it (*cf. Chem. & Ind.*, 1923, p. 405). The potassium carbonate had been found to contain 10 parts of arsenic and 80 of lead per million, and samples sent to him had given the same results for arsenic but were even higher in lead. The bottle contained both arsenic and lead and had been long in stock. The samples of potassium carbonate stored in it had been traced and were all below the pharmaceutical limits, and new samples put in the bottle gained lead.

Mr. Wilkie sketched the methods used for the analysis of lead glasses, which were now not used in the manufacture of storage bottles. The glass, even when in pieces, was easily brought into solution by fusion with alkaline carbonates. Potassium carbonate could absorb water, then cake, and give a film of saturated solution, to which the corrosion was probably due. Mr. Coad Prior said that this glass was an extraordinary sample. It contained, per cent., PbO 13·25, SiO_2 67, CaO 2·3, As_2O_3 0·38, and alkalis, by difference, 17·7. It was necessary to keep alkalis down, especially if lead was present. There might be 0·1 to 1·0 per cent. of arsenic in white glasses. He had confirmed the solution of lead from the glass by experiments with a paste of potassium carbonate.

Mr. Butler referred to the variations in the supply of glass bottles for the wholesale drug trade, and enquired what composition might be expected? Mr. Coad Prior, in reply, mentioned the composition of the principal kinds. The old bottles, which were hand blown, were low in alkalis and stable, but the mechanically made glass bottles were apt to be high in alkali owing to difficulties in manipulation and partly to the diminution in limestone with the object of keeping the iron low. He would like to see a definite standard of stability specified by the chemical industry to which glasses must conform. Alkalis should never be more than 16 per cent., and manufacturers were aiming at a minimum of 10 per cent. lime.

MEETINGS OF OTHER SOCIETIES

PHYSICAL SOCIETY

At the meeting held on March 27, the Research Staff of the General Electric Co., Ltd., London, presented a paper on "The Analysis of Bubbles in Glass." A piece of the glass containing bubbles is placed in one limb of a small quartz U-tube, the other limb of which is three-quarters filled with mercury. The tube is evacuated, precautions being taken against the presence of gas absorbed on the walls, and is then sealed off from the pump. The limb containing the glass is then heated until the glass is just soft: it is then plunged into cold water and the cold mercury from the other limb simultaneously thrown on the hot glass. The process is repeated several times, if necessary, until the glass is broken into fragments and the gas contained in the glass liberated. The spectrum of the gas is examined for nitrogen. If this gas is present, the bubbles in the glass have probably arisen from the introduction of air or furnace gases during ladling, stirring or pouring. If nitrogen is absent, the bubbles have probably been produced by generation of gas in the glass itself.

Dr. H. P. Waran described "A Simple Regenerative Vacuum Device," designed to deal with difficulties arising from residual traces of air fouling the vacuum above the mercury column in barometers, siphon gauges, mercury-vapour lamps, etc. The device consists of a small capillary tube bent into S-form and ending in a bulb fused on the top of the barometer or other tube. By inclining the tube, residual air may be pushed into the bulb, and its subsequent return to the tube prevented by mercury in the capillary.

Messrs. H. Shaw and E. Lancaster-Jones submitted a paper on the "Application of the Eötvös Torsion Balance to the Investigation of Local Gravitational Fields," in which determinations of the variations of gravitational attraction in the laboratory due to walls, pillars, etc., substantiate the claim made for the instrument both as regards consistency and sensitivity.

CORRESPONDENCE

THE JOURNAL

Sir,—You have received so many letters commending your weekly Journal that I fear this may not be of special interest, but I cannot help telling you that I have come to look forward to its arrival with much pleasure. Its appeal to me consists in the content of real science expressed in pleasing form for the reader. I have just read an example of this in Prof. Louis' article on "The Production of Lead in Great Britain," which recalls the Rev. B. V. White's promise to write something about lead in storage batteries.

This type of writing should make a special appeal at the present time to your American readers. They are making an effort through *Science Service*, directed by the American Chemical Society, to put real chemistry before the eyes of the newspaper-reading public, and the women's clubs are helping by having lectures on chemistry at their meetings.

I undertook to interest the women's club of this city in the question by calling on the president one afternoon and reading to her the "Notes from Heathfield." It seems as though the women of Leaminster with its English name should be interested in the chemistry of England so charmingly told. Such seems to be the case, and I hope to bring your Journal again to the attention of the women here.

This popular appeal is not only of value to the general public, but reacts to benefit the chemist himself who will find the preparation of a subject for a lay audience a clarifying process. It is very easy to say that certain matters are not within the compass of the average understanding. This may be partly the fault of the chemist himself who, lacking a clear concept, fails to express himself adequately. I have found many flaws in my chemical reasoning when trying to get it in form to explain to someone unfamiliar with my subject.

Even an audience of chemists is often for the most part unfamiliar with the subject of the speaker and usually welcomes a lecturer who employs a simple, non-technical diction. A few facts prepared for easy assimilation will be retained by the ordinary mind whereas one can hardly be on the alert to catch continuous bursts of genius throughout an entire lecture. The same is true within reason in reading, and while it would not do to fill the journals with too much irrelevant matter, there is surely no harm in having the reading part simple. Your Journal has, to my mind, struck a happy medium in this respect, and I think it should serve as a model for chemical society publications.—I am, Sir, etc.,

Clarence Joyce

Leaminster, Mass., U.S.A.
April 11, 1923

"AN EMPIRICAL RULE FOR SUBSTITUTION IN THE BENZENE SERIES"

Sir,—I have already shown (*Chemical Age*, Oct. 28, 1922) that even a very long series of coincidences is insufficient to prove the truth of an empirical rule. To Miss Hoffert's rule (*Chem. and Ind.*, 1923, p. 348), there is the following further objection :—Since the successive members of a homologous series must have a constant difference of six valency electrons, the directing effects must follow in cyclic order the series—(*i*) o.p. (*ii*) o.p. ; m. (*iii*) m. ; o.p. (*iv*) m.

Experimental results in any family of homologous benzene derivatives—e.g., alkylbenzenes, alkylanilines, phenyl alkyl ethers, alkyl benzoates —show that the directing effect is, on the contrary, practically constant.

A similar cyclic order should hold for substitution in the series $C_6H_5[CH_2]_n.X$, where X is any monovalent group and $_n$ is 1, 2, 3, etc.

Further, $.OCH_3$ is one of the most powerful *o.p.*-directing groups—a fact scarcely indicated by the sum of its valency electrons (13).—I am, Sir, etc., Cecil Hollins

Research Department,
British Dyestuffs Corporation,
Manchester

THE TITLE "CHEMIST"

Sir,—A discussion on the title of chemist can at the present time have no practical result ; it is obviously logical that persons engaged in the science and practice of chemistry should be termed "chemists," in fact, there is no other word in the English language which is effective for describing them ; it must be remembered that chemistry, as it exists to-day, is a young science, and a century ago there were no chemists, and it was the pharmacist of the day who came most nearly to the practice of chemistry.

Pharmacy has developed contemporaneously with chemistry, but along gradually diverging lines, and though it is not entirely divorced from chemistry, this science now enters to but a minor degree, and the description chemist as applied to a pharmacist has ceased to be a true one to the logical mind. Nevertheless, it still remains, and cannot at the present time be displaced ; the Pharmacy Acts have conferred a legal right on the pharmacist to be a chemist—public opinion holds that he is a chemist—and within the last few years a powerful vested interest has arisen.

It is true that the law can be changed, but the difficulties of making such a change in face of public opinion and vested interests are insuperable. In addition, few, if any, chemists have a real grievance ; what class of "chemists" desires the change ? The academic chemists show no signs, the analysts and consultants are not up in arms, the technical chemists are not clamouring, and it seems that it is really people whose knowledge and skill in chemistry are so small that their recognition as chemists is problematical who are most desirous of getting the—or a—title.

Our friends the pharmacists who have the legal right to be chemists have never made the least effort to prevent any bona fide student or practitioner of chemistry from calling himself a chemist, so long as he refrained from keeping open shop, and from their side the subject has been regarded with a reasonable spirit of compromise ; while the leaders in pharmacy recognise, as do the leaders in chemistry, that the change is bound to come eventually, and the chemist will some day be called a chemist and the pharmacist a pharmacist, they know the time is not yet ripe. Let us therefore continue the compromise and devote our attention to the education of public opinion. —I am, Sir, etc., H. Droop Richmond

Boots Pure Drug Co., Ltd.,

THE CHEMICAL SOCIETY'S LIBRARY

Sir,—As a member of the Society of Chemical Industry I visited the Library of the Chemical Society to seek information on a subject which is interesting me at the moment.

With your acquiescence, I would like to record my appreciation of the services which the staff on duty in the Library rendered on this occasion. The volume I required was not available for reference or immediate loan ; but, notwithstanding the meagre ideas I conveyed to them on the subject, they spared no efforts to find other volumes or references which might aid me.

Perhaps other members of this Society in difficulties would welcome the sympathy meted by this excellent staff, and, no doubt, some will be able to confirm my experience.

In any case, it is certainly a sign of the bonds of good fellowship which exist between the Chemical Society and the Society of Chemical Industry.—I am, Sir, etc.,

Acton, W. 3 David M. Freeland
April 26, 1923

THE TAXATION OF MOTOR-FUEL

Sir,—I have no desire to enter into a controversy with Dr. Ormandy, nor indeed any intention of doing so, and much of his criticism would have been relevant and logical had I proposed the calorific value as a basis of the selling price of motor spirits and not merely of their taxation. We all know that calorific value is not the only point of importance in choosing a fuel, and also that the engine, and especially its compression, must, to get the best results, be suited to the fuel used, but the choice and the price he is prepared to pay may safely be left to the motorist himself, as it is at present, and, in my opinion, this is not a matter in which the Government should interfere. In any case, the basis I have proposed does not tell against the use of alcohol as Dr. Ormandy seems to suggest, since its calorific value being low, the tax per gallon would also be a low one. If, as is true, alcohol is taxed unfairly already by the use of expensive denaturants, the natural remedy would be to allow it to be mixed under bond, with benzol or some other suitable spirit, which would in itself be a sufficient denaturisation. A flat rate on all motor-fuels would almost exclude the use of alcohol, which, alone, is unsuitable for most of the cars at present on the road, and it was largely to avoid this that I proposed the calorific basis.

The taxation of motor fuels on any basis will be a problem of much difficulty, and if a separate rate is to be fixed for each of the hundreds of possible variants, an insuperable one, whilst a "flat rate" would, at least for the present, tend to exclude all fuels such as alcohol, of which the fuel-value is low; and to get over these difficulties, some sort of a physical standard seems to me essential.—I am, Sir, etc., HENRY R. PROCTER

THE NITROGEN INDUSTRY

SIR,—In his careful and informative review of the book by Dr. Parker and myself, in the issue of April 27, Dr. J. A. Harker, F.R.S., has made one or two statements which it seems desirable to comment upon. I take it that the best practice in these matters is for authors to accept the opinion of a reviewer if he says a book is bad—a circumstance which, I believe, is not in evidence here; but if there are statements on matters of fact on which the author and reviewer differ, then it is perhaps of general interest that there should be a little discussion. In this case it must be with the realisation that, but for the reviewer, neither of us would ever have found himself in the position of being an author of any book on the nitrogen industry. In the first place, I think Dr. Harker has been a little unfair in suggesting that the book is written around the Reports of the Nitrogen Products Committee. When we had to deal with statistical matters we turned, naturally, to these; but even here not exclusively, as the reader will see. The bulk of the information contained in the book has no relation to these Reports.

The statement that: "The volume may be regarded as bearing the same sort of relation to the Nitrogen Products Committee's Report as Mr. and Mrs. Sidney Webb's Commentary to the famous Minority Report on the Poor Law," is, therefore, probably exaggerated, although, as I am not acquainted with either of these latter documents, I cannot speak with certainty.

I believe that our criticism of national policy with regard to nitrogen fixation is amply justified by the statement made by the reviewer that, although ammonium nitrate formed 80 per cent. of the principal explosive used in the past war, it is now imported from abroad: "all the ammonium nitrate works which operated during the war having apparently been dismantled." If dyes and optical glass *must* be maintained in being for national safety, what are we to say on this matter?

Dr. Harker states that a certain number of our statements "are not in accord with the facts." In a subject which is moving rapidly this may be unavoidable, but I believe that, apart from inevitable errors, the statements as to "the ineffectiveness of the Government policy and the comparative lack of actual achievement in nitrogen matters," to which he seems to refer, were completely justified when they were written, and, to a large extent, are true to-day. At any rate, we have no information to the contrary, much as we should welcome it. I believe that the "technical experts" will take our thrusts in the joust as cheerfully as we "pure" chemists have taken theirs in the past. Perhaps we have taken them lying down too long, and signs of life in us will not, I feel sure, impair that fine chivalry which has so long been associated with knightly encounters—at any rate, during the period when knights were liable to be called upon to defend their titles. When we have our armour off we shall, I hope, continue to find mutual satisfaction in a joint existence. Davy's "jibe" may, as we ourselves point out, have been rather extravagant, but even in a dog-fight one likes to see both parties getting fair play, and in recent years one dog has usually been bigger and has barked louder than the other.—I am, Sir, etc.,

CALCIUM LACTATE

SIR,—I note in the *Journal* of the 27th inst., just to hand, under the Market Report, the price of calcium lactate is given as being 2s. 9d. per lb. It may interest you to know that I have recently seen a German quotation for B.P. calcium lactate at £18 per ton in barrels, U.K. port: payment to be made 26 per cent. in Customs Dues, the balance by draft on Bank.

This low price, taken into consideration with the result of the experiment made here in the course of the Ministry of Agriculture and Fisheries' work on the utilisation of whey, of which I sent you a note on December 23 last, much concerns, but does not discourage, me; for, if in the preparation of the lactate from whey a multiple effect evaporator be used, it is still possible to compete with the outrageously low figure quoted.—I am, Sir, etc.,

PERSONALIA

The Faraday Medal of the Institution of Electrical Engineers is to be presented to the Hon. Sir Charles A. Parsons, at the meeting on May 10, at 6 p.m.

Mr. A. R. Warne, A.Inst.P., M.I.Mech.E., has been elected President of the Hull Chemical and Engineering Society for the year 1923-24.

Dr. H. H. Dale, C.B.E., of the Medical Research Council, has been appointed a member of a committee constituted to investigate the comparative therapeutic value of various cocaine substitutes, and the evidence of risk, if any, that such substitutes may become drugs of addiction.

It is announced that Dr. C. E. K. Mees, who, it will be remembered, left England in 1908, to become the first director of the Eastman Research Laboratory, has now been made a director of the Eastman Kodak Co.

NEWS AND NOTES

FRANCE

Notes from Paris

It has already been announced that the centenary of the birth of Pasteur will be commemorated on May 26 to 30 in Paris, then at Strasburg from May 31 onwards. In Strasburg, in the presence of delegates from all over the world, the monument to Pasteur erected in front of the University from an international fund will be unveiled. In addition, the Pasteur Museum, situated near the Institute of Hygiene and Bacteriology of Strasburg, will also be opened. This museum will be devoted to exhibits illustrating Pasteur's researches, ranging from crystallography, ferments, silk-worm disease, fowl cholera, anthrax, diseases of beer, to alcohol, fermentation and applications to medicine and surgery. On June 1 the Industrial Exhibition will be inaugurated showing the vast bearing of Pasteur's discoveries on the progress of hygiene and agriculture. In the section for hygiene will be shown the various applications to military, marine, colonial and other uses. Exhibits will also be devoted to chemistry, chemical industry, agriculture, cold-storage, etc. Particularly at this moment when the question of nitrogen fixation is attracting the attention of so many nations, it should not be forgotten that it is thanks to the researches of Pasteur that it is now possible to elucidate the action of soil bacteria, nitrifying and other organisms, and it is permissible to prophesy that in the future the soil will be fertilised by means of selected bacteria that, without any consumption of high-potential energy, human effort or limitation of working life, will return to the soil certain of the fertilising principles removed by the plants.

UNITED STATES

The Artificial Silk Industry

The production of artificial silk in the United States during 1922 was 24,406,000 lb., as compared with 15,000,000 lb. in 1921, 5,828,000 lb. in 1918, and 1,566,000 lb. in 1913. Figures are not available of the imports of artificial silk in 1922, but it is believed that the amount will be less than in 1921, when 3,667,180 lb. was imported.—(*Ch. Comm. J., Apr.* 27, 1923.)

GENERAL

The Norwegian Carbide and Cyanamide Industry

There are now eight modern carbide factories in Norway, three having been built during the war. With a total h.p. of 170,000, the plants have a total output-capacity of 250,000 tons of carbide per annum, and when in full operation employ about 3000 men. At present several factories are closed and others are operating at reduced capacity. The anticipated increase in consumption after the war, which led the industry to expand its capacity to 80 per cent. of the world's total output (350,000 t. per annum) in 1913, has thus proved illusory. The sole cyanamide factory in Norway, situated at Odda, has been closed for over a year, and it is unlikely that this factory or the carbide factory in the same district will ever be operated again, unless new uses are found for both carbide and cyanamide.

The Uses of Zinc Dust

An interesting list of the uses of zinc in the powdered state is quoted in a recent issue of *Chemical and Metallurgical Engineering* (Apr. 9, 1923). The chief properties for which zinc dust is used may be summarised as follows :—(*a*) Reducing properties, as in the dye industry, for reducing nitro compounds to organic amines and in preparing sodium hydrosulphite for the reduction of vat colours ; (*b*) the property of precipitating metals from their solutions, in purifying zinc-sulphate solutions for electrolysis or for the manufacture of lithopone ; (*c*) the property of combining with dry oxygen only at a high temperature, and of giving with moist air a basic carbonate or with sea air an oxychloride which protects the metal from further alteration. These properties have led to application in painting iron objects, sherardising (*i.e.*, immersing iron objects in zinc dust at 300° C.), galvanising cast-iron and metallisation (*i.e.*, deposition by projection of a layer of zinc on the surface of a metal). Zinc dust is usually obtained as a by-product from zinc smelters, but it is also made by blowing gas against a stream of liquid zinc or by grinding. Such dusts contain varying amounts of impurities, some of which are undesirable for certain uses. Microscopic examination has shown that the grains of zinc dust consist of metallic globules coated with crystals of zinc oxide which prevent the globules from uniting.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for April* 26)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Chemicals, coal-tar oil, hides	559
Canada	Earthenware	11000/E.D./G.C./2
,,	Plant for distillation of alcohol	11007/E.D./C.C./2
,,	Stearin, palm oil	*
Cuba	Soap	561
Kenya Colony	Paper-pulp, paper (tender)	11077/E.D.
Netherlands	Photographic chemicals, fertilisers	547
New Zealand	Drugs, medical supplies	534
,,	Asbestos sheets, chemicals, enamel and aluminium ware, gas mantles	535
Rumania	Iron (tender)	10517/F.E./E.C.
South Africa	Iron and steel	537
,,	Sodium arsenite (tender)	11059/E.D./C.C./2
Sweden	Steel	7209/F.R./E.C./2
Switzerland	Upper leather	19117/F.W./M.C./2
,,	Pharmaceutical specialities	19094/F.W./C.C.
United States	Iron and steel	554
,,	Steel	18677/F.W./E.C.

* Canadian Government Trade Commissioner's Office, 73, Basinghall Street, E.C. 2.

TARIFF CUSTOMS EXCISE

British India.—Numerous amendments have been made to the Indian Customs Tariff, among which are the imposition of an import duty on saccharine at the rate of Rs. 20 per lb. instead of 25 per cent. *ad valorem*; and the reduction of the export duty on raw hides and skins from 15 to 5 per cent. *ad valorem*.

Egypt.—The prohibition of the importation of sugar and glucose has been withdrawn.

France.—A law has been passed which fixes the duties on compound medicines. The export and re-export of ammonium sulphate has been prohibited.

Germany.—Export duties have been reduced or withdrawn on a number of articles, including cement, lime, chalk, graphite, emery, wood pulp, and mica.

Germany (*Occupied*).—Import duties have been levied on perfumes containing ether or ethyl alcohol, essences, tinctures and waters.

Norway.—The stamp tax on chocolate and sugar goods has been renewed.

Poland.—An additional duty of 90,000 Polish marks per 100 kg. is to be charged on coarse and refined sugar, and the duty on acetic acid has been increased to 3000 Polish marks per kg. of undiluted acid.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Petroleum Exploration in Great Britain

In reply to Mr. Houfton, Lieut.-Col. Lane-Fox said that the total expenditure on exploration for petroleum in Great Britain, allowing for amounts realised by sales of oil, plant and machinery, was roughly £564,000. Oil was found in appreciable quantities at only two of the eleven borings, and these two bores had been sold—the D'Arcy bore to a Scottish syndicate and the Hardstoft bore to the Duke of Devonshire—in order to prevent further loss.—(Apr. 24.)

Opium Production in British India

Replying to Mr. Ponsonby, Earl Winterton said that in the year ending October 31, 1921, the number of chests of opium manufactured in British India was 12,524, of which 5800 chests were for export and 6724 chests for internal consumption; during that year, the opium poppy was grown on 116,056 acres.—(Apr. 24.)

Tar for Road Works

Lieut.-Col. Campion, in a written answer to Col. Ashley, said he could not admit that the use of ordinary crude gas-tar for road-works had generally given satisfactory results. To secure a tar of known constituents and qualities, the Roads Department had drawn up a specification, which must be observed to obtain grants from the Road Fund, but Local Authorities were not debarred from using crude tar.—(Apr. 21.)

Home-Grown Sugar

Mr. Baldwin informed Mr. Barnes that the difficulties which British Home Grown Sugar, Ltd., had to face were due mainly to the fact that this very technical industry was in its infancy in this country. The recent reconstruction of the company and the improvement now in hand of the Kelham sugar-beet factory should result in the establishment of the industry on a firm basis.—(Apr. 26.)

REVIEW

Soap Making Manual. *By* E. G. Thomssen, Ph.D. *Pp. viii*+243. *New York: D. van Nostrand Co.; London: Crosby Lockwood and Son*, 1922. *Price* 12*s*. 6*d*. *net*.

In this book, the material for which appeared some time ago in the *American Perfumer and Essential Oil Review*, the author has attempted to deal with soap-making processes and glycerin recovery from the purely practical standpoint. Whilst much of the information is necessarily of the usual kind associated with the ordinary text-book on soap manufacture, a very fair account is given of processes which are, or have been, recently in use in modern practice.

A practical description is given of the ordinary boiling process, which shows a working acquaintance with the subject, and the saponification of rosin and the preparation of " closed " or " glued-up " soaps are treated satisfactorily. Cold process, half-boiled soaps, shaving soaps and creams are treated in the conventional manner, but in the section on transparent soaps the author's assertion that they are of little use because they must contain an excess of alkali cannot, of course, be accepted.

The whole of the information regarding the composition and nature of household and laundry soaps is obviously written for American readers, and the oils and fats are not necessarily those used for corresponding soaps in Europe. The section on textile soaps is not satisfactory and in some respects the book is very unevenly written, the desire to be practical overcoming in some cases the clearness of the text.

The chapter on glycerin recovery is much on the ordinary lines, but the optimism of that dealing with the future of hydrogenated oils as soapmaking materials is quite out of date, the information contained therein being the views of twelve or fifteen years ago.

The latter half of the book is occupied with simple analytical data and a complete report of the standard methods of analysis of commercial fats and oils adopted by the American Chemical Society.

The illustrations, which are all placed at the end of the book, although poorly printed, represent up-to-date machinery in a modern American factory. An appendix also contains a collection of tables of strengths of solutions and specific gravities, and whilst on the whole the book cannot be said to contain much that is new, it is more practical than many which have been published on the subject.

F. G. Reynolds

At the recent Toronto meeting of the American Biochemical Society, P. A. Schaffer was elected president, and H. C. Sherman, vice-president, for 1923.

MARKET REPORT

This market report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

A continuation of recent improvement in the demand for chemicals is accompanied by a firm tendency in prices, especially so in the cases where supplies from Germany show a falling off. Makers have reduced the delivered prices of one or two products in conformity with the promised reduction in railway rates from May 1, and have thus passed on the advantage to buyers where possible. The position of Acetic Acid is at present particularly uncertain, as anticipated large demand in America has resulted in a reported advance of Acetate of Lime to about £23 per ton, and the state of the market is now chaotic with practically nothing available.

Acid Acetic, 40% tech. ..	£23-£25 per ton. Still firm but position seems slightly easier owing to more foreign acid entering than of late.
Acid Hydrochloric ..	4s.-5s. per carboy d/d.
Acid Nitric	£24 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric— 94% Arsenical ..	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d.-£8 per ton. Demand still improving.
Arsenic (White) ..	£70 per ton. Price more or less nominal.
Bisulphite of Lime ..	£7 per ton, packages extra.
Bleaching Powder ..	Spot £11 7s. 6d. d/d. Contract £10 7s. 6d. d/d.
Calcium Chloride ..	£5 17s. 6d. per ton d/d. Reduction of 2s. 6d.
Copper Sulphate ..	£27 per ton.
Potash Caustic	Spot about £35 per ton. Small quantities available.
Potass. Bichromate ..	5¾d.-6d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.-£5 per ton. Export inquiry well maintained.
Soda Caustic 76% ..	£20-£21 per ton.
Soda Crystals	£5 10s. per ton. No change.
Sod. Acetate 97/98% ..	£26 per ton. Very scarce.
Sod. Bicarbonate ..	£10 10s. per ton. No change.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton, according to quantity.
Sod. Chlorate	3d. per lb. No change.
Sod. Nitrite 100% basis	£28 per ton d/d.
Sod. Sulphide, conc. ..	£16 per ton carr. paid. Decided improvement for both home and export.
Sod. Sulphite, Pea Cryst.	£17-£17 10s. per ton, according to quantity.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.

Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£26-£28 per ton according to quantity.
Carbon Black	1s. 5½d. per lb. ex wharf.
Chromium Oxide	1s. 5d. per lb.
India Rubber substitutes, White and Dark	5½d.-6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber ("Rubpron")	£16-£18 per ton.
Sulphur, Finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£10 15s. per ton d/d.
Grey	£20-£23 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 10s. per ton d/d.
Brown Sugar of Lead	£40 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 6d. per lb. Still fair inquiries but prices are slightly lower for delivery second half of year.
Crude 60's	3s. 9d. per gall. Market steady but demand rather less.
Acid Cresylic—97/99	2s. 2d.-2s. 5d. per gall. Fair demand.
Pale 95%	2s.-2s. 4d. per gall. Steady business.
Dark	1s. 10d.-2s. 0½d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. Market stagnant.
Anthracene Oil—	
Strained	9½d.-11½d. per gall. Fewer inquiries.
Unstrained	9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8½d. per gall.
Pure	2s.-2s. 2d. per gall.
Toluole—90%	1s. 9d.-2s. per gall.
Pure	2s. 2d.-2s. 6d. per gall.
Xylol	3s. 3d.-4s. per gall., according to quality.
Creosote—	
Cresylic 20/24%	11d.-1s. 1d. per gall. Little business passing.
Middle Oil	8½d. to 11d. per gall. Market somewhat easier.
Heavy	
Standard Specification	
Naphtha—Crude	9d.-9½d. per gall.
Solvent 90/160	1s. 7d.-1s. 9d. per gall. Fair business passing.
Solvent 90/190	1s. 6½d.-1s. 8d. per gall. Not much demand.
Naphthalene, Crude—	
Whizzed or hot pressed	£11-£14. Supply still scarce.
Drained Creosote Salts	£7-£10 per ton. Market firm.
Pitch, Medium Soft	No business for this season. Prices for autumn delivery 140s.-150s. per ton.
Pyridine—90/140	11s.-12s. per gall. Price nominal. Very few inquiries.
Heavy	8s.-9s. Price nominal. No inquiries.

INTERMEDIATES AND DYES

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhydrous	1s. per lb. d/d.
Aniline Oil and Salts	9½d. per lb. naked at works. Good demand.
Antimony Pentachloride	1s. per lb.
Benzidine Base	8s. 6d. per lb. 100% basis.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlor Phenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
p-Dichlorbenzol	£70 per ton.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d, packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
α-Naphthol	2s. 9d. per lb.
β-Naphthol	1s. 1d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d.-8d. per lb. Market very brisk.
Nitronaphthalene	1s. per lb. d/d.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sod. Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid Acetic 80%	£52 10s. per ton.
Acid Acetyl Salicylic	3s. 6d. per lb. Firmly held.
Acid Benzoic	2s. 3d. per lb. In very short supply.

Acid Citric	1s. 8¾d.-1s. 9d. per lb., less 5%. Demand good and prices firm.
Acid Gallic	3s. per lb. for 2-cwt., 3s. 3d. per lb. for 56 lb. lots.
Acid Pyrogallic, cryst.	5s. 9d. per lb.
Acid Salicylic	2s. 6d. per lb.
Acid Tartaric	1s. 3¾d.-1s. 4¼d. per lb. Demand good and prices still advancing.
Ammon. Carbonate B.P.	£37 10s. per ton.
Barbitone	18s. per lb. still quoted without much demand.
Benzonaphthol	4s. 6d. per lb. higher.
Bromides	Nothing now coming forward from the Continent at London spot prices, which are consequently showing a firmer tendency.
Chloral Hydrate	3s. 9d. per lb. Would be accepted for 5-case lots.
Creosote Carbonate	10s. per lb. Dull at this figure.
Formaldehyde 40%	£87 10s. per ton.
Guaiacol Carbonate	8s. per lb. lower.
Hexamine	4s. 6d. per lb. Still fully maintained.
Homatropine Hydrobromide	30s. per oz.
Magnesium Carbonate—	
Light Commercial	£38 per ton nett.
Magnesium Oxide—	
Light Commercial	£85 per ton nett, less 2½%.
Heavy Commercial	£28 per ton nett, less 2½%.
Menthol	35s. per lb. spot. Advanced.
Methyl Salicylate	2s. 8d. per lb. for carboys still quoted.
Methyl Sulphonal	14s. 6d. per lb.
Paraformaldehyde	4s. per lb., showing no alteration from last quoted rates.
Paraldehyde	1s. 7d. per lb.
Phenacetin	6s. 6d. per lb.
Phenazone	7s. 6d. per lb.
Phenolphthalein	5s. 6d. per lb.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	98s. per cwt., less 2½%. Firmer.
Potass. Iodide	15s. 8d. per lb. in cwt. lots. Good steady demand.
Potass. Permanganate	11d. per lb. is the general price for quantity. No parcels appear to be on offer at a lower figure.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz.
Saccharin	Increasing demand.
Salol	2s. 9d. per lb. Unchanged.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 4d. per lb. is now wanted. In very short supply.
Sod. Citrate	U.S.P. quality 2s. 2d. per lb. for cwt. lots. Good orders have been taken at this figure.
Sod. Hyposulphite—	
Photographic	£15-£17 per ton.
Sod. Salicylate	2s. 9d. Powder, 2s. 11d. per lb. Crystals, best makes.
Sod. Sulphite, anyhdrous	£27 10s.-£28 10s. per ton. f.o.r. London, 1-cwt. wooden kegs included.
Sulphonal	14s. per lb.
Thymol	16s. 6d.-18s. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil, Red Ship Brand	2s. per lb.
Bergamot Oil	12s. 6d. spot, 13s. 6d. forward.
Cananga Oil, Java	9s. per lb.
Cassia Oil, 80/85%	8s. 3d. per lb.

TRADE NOTES

BRITISH

Trade Information

Chemical Lime.—The Callow Rock Lime Co., Ltd., has issued an interesting booklet describing the history, production and uses of chemical lime. The various properties of lime and their importance in chemical processes are discussed and an extensive list of uses is detailed. After describing the methods of producing Callow Rock lime, an interesting series of tables is given showing the chemical and physical characters of this lime, concluding with a list of the special products made by the company. Those interested can obtain copies of the booklet on application to the Callow Rock Lime Co., Ltd., 811, Salisbury House, London, E.C. 2.

Glassware.—We have received from Messrs. Ackroyd and Best, Ltd., of Beacon Works, Morley, Yorks, an illustrated catalogue of the specialities produced by this firm. Special interest attaches to the safety lamps made by this company, which also turns out a large variety of glassware, including opal, clear and heat-resisting glass for lighting and other purposes.

Necol Plastic Wood is a pliable material of use for moulding intricate parts of patterns, and for filling holes, etc. in woodwork. The material, made by Necol Industrial Collodions, Ltd., a constituent company of Nobel Industries, Ltd., of London, is waterproof, dries hard quickly, and can be cut to shape with tools and even turned on a lathe. Further information is given in a booklet issued by Nobel Industries, Ltd., who will supply further particulars to inquiriers.

Messrs. Chas. Page and Co., Ltd., inform us that their address is now 37—39, King William Street, London, E.C. 4, where all their departments are now housed.

Messrs. Munton and Baker (Bedford), Ltd., have transferred their head office from Mark Lane to the "Muntona" Works, Bedford.

FOREIGN

Industrial Notes from France

Owing to the arrival of coke from the Ruhr, a few blast furnaces have been relit in Lorraine, the Société Métallurgique de Knutange, the Aciéries de Rombas, and the Mines et Usines de Redange Dilling having each relit a furnace.

The Etablissements Kuhlmann, in co-operation with the Société Algérienne de Produits Chimiques et d'Engrais and of the Crédit Commercial de France, has founded the Cie. des Superphosphates et Produits Chimiques du Maroc, which will operate a superphosphate factory at Casablanca under a contract signed with the Cherifien Government in September, 1921.

Dutch Vegetable Oil Industry

The output of vegetable oils in Holland during 1921 totalled 157,437 tons as against 106,733 t. in 1920, an increase of over 50 per cent. above the figures for 1913. Of individual oils, the production was as follows:—Linseed oil 73,017 metric tons, coconut oil 64,942 m.t., peanut oil 12,632 m.t., and rape-seed oil 5,238 m.t., in addition to smaller quantities of sesame, soya-bean and palm-kernel oils, the production of which has declined steadily since the war.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, MAY 11, 1923 No. 19

EDITORIAL

WE feel sure that if the objects of the Federal Council Fund were better understood there would be a more speedy response to the appeal made for it. The Federal Council, as has already been explained, has two objects in view; the first, to have such a fund as will enable the annual expense of sending delegates to meetings of the Union Internationale and the occasional expense of holding a meeting in this country to be provided; the second, to have a fund which will steadily be augmented and accumulated as a nucleus ready for the time when steps may be advantageously taken for that closer co-operation between the various societies represented on the Federal Council, which appears to be so desirable, and will in course of time, certainly be brought about. What form such co-operation will take no one can at the moment predict, nevertheless, it is already obvious that one building to provide accommodation for a number of such chemical societies will be necessary, and some capital sum sufficient to enable chemical publications, whether periodical or otherwise, to be issued in a manner worthy of our science and our country.

The funds necessary for all such purposes are considerable, and soon a real campaign must be started for their collection. This means an appeal in a more or less public manner, and one of the first essentials is a preliminary list of subscriptions as evidence that the movement for co-ordinating the social, literary, academic, industrial and commercial activities of chemists, has the support of all the great classes concerned. Such a public appeal cannot be long delayed.

In the meantime the nucleus fund is growing, but so slowly that steps must be taken to stimulate its growth. The invested funds of the Federal Council are now merely £300 in 5 per cent. War Loan, £150 Funding Loan, and £150 Victory Bonds. The response from those who felt disposed to contribute £10, £20 and £50 was fairly quick, but up to now the promises of smaller sums, the half-guineas, guineas and two guineas, have been singularly few. Now, if we are to realise the hope of placing chemistry in its proper place in the eyes of the public, all must lend a hand. There is no reason why four or five thousand of our readers should not promise some donation; those who are unable to give a large sum can help by sending a small one. The promise of a number of small sums stimulates the comparatively wealthy members of the community to be generous, and every name added to the list of subscribers is a stimulus to a number of friends and acquaintances to do likewise. We hope shortly to be in a position to publish the first provisional list of subscribers, and shall be very glad if our readers will let our editor know in the course of the next three weeks the assistance which may be expected. Some readers may like to contribute a sum the payment of which may be spread over two or three years; the large capital sum is not needed in the course of this summer. What is needed is a constant effort spread over the next five or ten years, so that the £1000 already promised will shortly grow to £5000 or £10,000. This will give us chemists a chance of keeping the capital intact and paying the necessary expenses out of a portion of the interest, accumulating the residue and continuing the appeal with confidence. The time will then come when we can ask for large donations, and see our way to tackling the large problem. At the moment the need is for a considerable number of small sums, and we hope that when we are authorised to publish the first list of promises it will be a really long one.

* * *

It was to be expected that the isolation of insulin and its production on a certain scale would lead to the publication of further work bearing on the subject. Some weeks ago, it was announced by Messrs. Winter and Smith that a substance similar to insulin could be obtained from yeast and that this substance, when administered to diabetic patients, acted like insulin in freeing the blood from sugar. In addition, Mr. J. B. Collip, of the University of Alberta, states in a cable to *Nature* that his previous prediction that wherever glycogen occurred in Nature an insulin-like substance would be found, has been corroborated by experiments with clam tissues and later with yeast. But Mr. Collip has also found that extracts made from various plants (onion, barley, lettuce) produced marked hyperglycæmia in normal rabbits, and that extract of green onion tops given to a depancreated dog reduced the blood-sugar content by over one-half. The name proposed by Mr. Collip for this new plant hormone is "Glucokinin," and it is to be hoped that not too long a period will elapse before something more will be known of plant and animal hormones and, indeed, of vitamins, than their names and some of their less recondite reactions. The importance of such work can hardly be over-estimated, for it means not only that alleviation is being procured for human suffering, but that knowledge is gradually being acquired of the mechanisms of vital reactions, with the promise of ultimate consequences that may surpass the wildest fantasy. Another discovery of far-reaching importance is the elaboration, by a member of the staff of the Imperial Cancer Research Fund, of a saline solution in which body tissues can be sustained in more or less continuous life and growth. Thus kidney cells grow in such a solution and produce sheets or lumps of tissue which, however, do not reproduce the special structure of the original organ; but if pieces of living connective tissue such as gristle are added, the cells take on the characteristic microscopic structure of the kidney; further, if broken-down healthy tissue or extract of cancer tissue be added, the rate of growth is greatly increased. The vital significance of such work is obvious and our only regret is that there are not more workers in the field, so that progress could be made more quickly.

* * *

It is pleasant to see how some of the great problems are gradually being solved. The utilisation of the great mass of nitrogen in the air is one of these. It is something like eighty years since the subject was first investigated, and we have become accustomed to think of nitrogen as an inert, dull and dreary gas, a mere diluent, but its properties in such substances as ammonium nitrate and T.N.T. show that the stability of its molecule is only evidence of the power and activity of its atom. Professor W. A. Bone has quite recently carried the story a little further. By exploding carbonic oxide and nitrogen together he obtains an active form of nitrogen, which in this state will combine with oxygen, and no doubt can be stimulated to form other compounds.

THE USE OF CO-ORDINATION COMPOUNDS IN ANALYSIS

By PROF. T. MARTIN LOWRY, F.R.S.

1. Analytical Separation of the Transition-Elements

The analysis, both qualitative and quantitative, of the metals of the three transition series has been revolutionised completely by the use co-ordination-compounds. Thus Matthey, in 1879, after carrying out an extremely tedious process of purification according to the ordinary methods of analysis, had to acknowledge that the purest iridium that he could prepare still contained traces of ruthenium, rhodium and possibly iron; indeed, at that time, the complete separation of the platinum metals appears to have been only less difficult than the separation of the rare earths. This position has been completely altered by making use of the fact that consecutive elements of these groups, although they differ from one another by only one planetary electron and exhibit in their ordinary compounds an almost constant valency of 2, 3 or 4, are extremely sensitive in relation to the processes of co-ordination, which may be thrown completely out of gear by the addition or removal of a single electron. This sensitiveness finds its most striking illustration in the compounds which have been selected for use in analysis, since only the most rigid discrimination between consecutive elements will meet the requirements of a complete qualitative separation or of an exact quantitative analysis. A few examples of co-ordination-compounds which fulfil these stringent requirements are set out below.

2. Metallic Carbonyls

"*A very complete separation of nickel from cobalt may be effected by reducing to the metallic condition and removing the nickel in the form of volatile nickel carbonyl by heating in a current of carbon monoxide. Cobalt does not yield a carbonyl under the same conditions.*"

Nickel with 10 electrons in its outer shell requires only 8 more to make up the stable system of 18 electrons which is characteristic of the inert gas krypton; it secures these by sharing 4 pairs of electrons with 4 molecules of carbonic oxide in nickel tetracarbonyl, NiC_4O_4 or $[Ni.4CO]$. Cobalt also unites with 4 molecular proportions of carbonic oxide; but, since it contains 1 electron less than nickel, the stable grouping of 18 electrons is attained by sharing 1 pair of electrons between 2 atoms of cobalt, giving rise to a *dicobalt octacarbonyl*, $Co_2C_8O_8$ or $[Co.4CO]_2$. The conditions for the formation and decomposition of this carbonyl, as well as its properties, differ widely from those of nickel carbonyl. Thus whereas nickel carbonyl, $Ni(CO)_4$, is a colourless liquid, boiling at 43·2° (f.p. -25°) and is produced at atmospheric pressures, and at temperatures below 50°, cobalt carbonyl, $Co_2(CO)_8$, forms orange-coloured crystals melting at 51°, and is produced at 150° under a pressure of 40 atmospheres. These differences, although they depend on the elimination of only a single planetary electron on passing from nickel to cobalt, are sufficiently wide to render possible a perfect separation of the two metals.

3. Double Cyanides

In order to separate nickel and cobalt "*the cyanides are precipitated and redissolved by the addition of potassium cyanide. By boiling a solution with a drop of acetic acid, the cobalt is converted into potassium cobalticyanide and cannot then be precipitated by sodium hypochlorite, whilst nickel remains as a simple double cyanide and is at once precipitated.*"

Potassium cobalticyanide owes its stability to the fact that it contains a tervalent cobaltic atom with only 6 electrons in its outer shell; the full complement of 18 electrons is therefore secured by sharing 6 pairs of electrons derived from 6 cyanogen groups. The tervalent anion, [Co.6CN], is therefore an extremely stable complex. Potassium ferricyanide, $K_3[\overset{+++}{Fe}.6CN]$, is also a fairly stable compound, although the anion contains 1 electron less than the anion of the corresponding compound of cobalt; but this missing electron is very readily acquired and the compound then passes over into the ferrocyanide, which contains the same stable configuration of electrons as the cobalticyanide. In the case of nickel this stable configuration could only be developed by the loss of 4 electrons. Since the valency of nickel in its salts is limited to two, the element is unable to form a double cyanide of sufficient stability to resist oxidation by sodium hypochlorite, and can therefore be separated quantitatively both from cobalt and from iron.

4. Double Nitrites

"*Potassium nitrite yields a yellow precipitate of potassium cobaltinitrite, $K_3Co(NO_2)_6$, when added to a solution of a cobalt salt containing free acetic acid.*" "*It is a bright yellow, crystalline powder, insoluble in water, and on account of its stability or inertness is used as an artists' pigment. It is a very pure compound when prepared as indicated above, for neither iron nor nickel yields a corresponding derivative; it is therefore valuable for painting porcelain, because the blue colour produced on baking is correspondingly pure and beautiful.*"

The nitrites are amongst the least stable of metallic salts and are usually decomposed even by organic acids. The extreme stability of potassium cobaltinitrite is due to the fact that a cobaltic ion with 6 electrons in its outer shell is able to make up the stable complement of 18 electrons by sharing 6 pairs of electrons derived from 6 nitrite groups. Nickel is unable to form a similar complex because the bivalent ion of the metal carries an excess of 2 electrons as compared with the tervalent ion of cobalt. Iron, on the other hand, is unable to form a similar complex because the ferric salts do not possess the number of electrons required to make up the stable grouping; and the ferrous salts which carry the right number of electrons are unable to persist under the oxidising conditions created by the presence of nitrous acid. Similar compounds are, however, formed by rhodium and iridium, the homologues of cobalt, the tervalent ions of which require 12 electrons to complete the complement of 18 electrons in the case of rhodium and 32 electrons in the case of iridium.

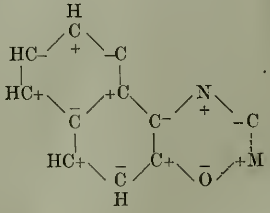
5. Glyoximines

"*Nickel may be precipitated from its ammoniacal or acetic acid solution by addition of an alcoholic solution of α-dimethylglyoxime. The voluminous scarlet precipitate is filtered through a Gooch crucible packed with asbestos and dried at 110° to 120° C. The nickel is either weighed as $C_8H_{14}N_4O_4Ni$, which contains 20·33 per cent. of metal, or ignited and weighed as oxide. Even more sensitive is α-diphenylglyoxime (α-benzil dioxime), which gives with nickel compounds a bulky red precipitate, insoluble in water, alcohol, acetone, ammonia and 10 per cent. acetic acid. It becomes reddish yellow on boiling. One part of nickel per 5,000,000 of water may be detected by this reagent. The estimation of nickel is conducted in a precisely similar manner to that with the dimethyl derivative, the precipitate being dried at 110° to 112° C., and containing 10·93 per cent. of nickel. The formula of the precipitate is $C_{28}H_{22}N_4O_4Ni$.*"

"*The method is available in presence of cobalt, iron, manganese, zinc, magnesium and chromium.*"

The nickel derivatives of the glyoximes are amongst the most remarkable compounds in the whole range of analytical chemistry. Tschugaeff, in describing dimethylglyoxime, HON:CMe.CMe:NOH, as a reagent for nickel (*Ber.*, 1905, 38, 2520) claimed that one part of nickel could be detected in 5000 parts of cobalt. In addition to their insolubility in water, and the highly selective character of the processes by which they are formed,—two *properties* which make them of special value in analysis—the *dioximines*, as Tschugaeff calls them, are possessed of quite remarkable stability. Thus the scarlet *nickel dimethyldioximine*, Ni(O.N:CMe.CMe:N.OH)$_2$, can be sublimed unchanged at 250°. Alkaline hydroxides and carbonates do not attack it, nor does hydrogen sulphide; weak acids also have no action, but with strong acids a reversible double decomposition takes place. The corresponding *palladium dimethyldioximine*, Pd(O.N:CMe:CMe.N.OH)$_2$, with a molecular weight of 365, can be sublimed without decomposition in a vacuum. The *platinous dioximines*, *e.g.*, Pt(O.N:CMe:CMe:NOH)$_2$, are even more stable than the corresponding compounds of nickel, since potassium cyanide appears to be the only agent which easily and completely decomposes them with separation of the free glyoxime; they are soluble in dilute alkalies and take up bromine to form dibromides. Like the palladium compounds, they can be sublimed without decomposition in a vacuum.

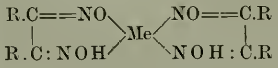
It is of interest to inquire into the origin of the stability of the complexes formed by these three metals, as well as into the highly-selective character of the action. By way of contrast it may be noted that, whilst cobalt can be precipitated quantitatively by means of nitroso-β-naphthol, the solution must be free from *copper*, *chromium* and *iron*. In this case the stability of the co-ordination-complex depends largely on the formation of a conjugated ring-system as shown in the formula I, in which the metallic ion $\overset{+}{M}$ acts as a member of a pseudo-aromatic ring. This action does not therefore possess the highly selective character which is exhibited in the case of the glyoximes.



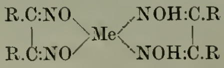
I

The structure of the dioximines is less obvious. Tschugaeff set out as possibilities the two alternative formulæ II and III.

II

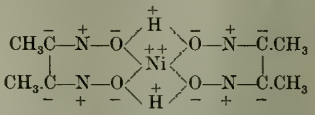


III



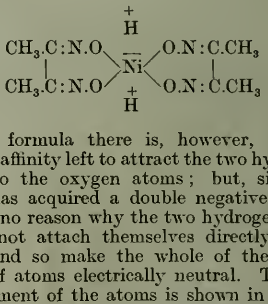
In the first of these the two "principal valencies" of the metal are attached to oxime groups on *two different molecules* of the glyoxime, whilst in the second both principal valencies are attached to *the same molecule* of the glyoxime, the other molecule being held (like a double salt) by "subsidiary valencies" only; in both cases, however, ring-formation was regarded as an important factor in promoting co-ordination. Assuming, provisionally, that Tschugaeff's first formula is correct, it is still by no means clear how the subsidiary valencies are brought into play, since the metal might conceivably be co-ordinated with any one of the three atoms of the oxime group, :NOH, or even with the group as a whole. By making use of the system of polar double bonds a clearer interpretation becomes possible since, of the three atoms of the oxime group, only the oxygen is shown as negatively charged. The secondary valencies of the positively-charged nickel must therefore be associated with the negatively-charged oxygen atoms of the oxime groups. This gives rise to the symmetrical formula IV:—

IV



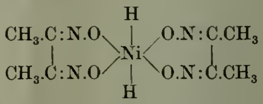
in which, however, a further element of symmetry has been introduced by assuming that the two hydrogen atoms are each co-ordinated with *a pair* of oxygen atoms, just as the bivalent nickel is co-ordinated with *two pairs* of oxygen atoms. In this scheme the nickel is shown as building up a shell of 16 electrons by sharing 4 pairs of electrons with 4 co-ordinated oxygen atoms. This sharing has the effect of uniting the metal by covalencies to the 4 oxygen atoms; but it also transfers to the nickel 1 electron from each oxygen atom. This makes the 4 oxygen atoms neutral (compare the 6 chlorines in Sidgwick's formula for the platinichlorides (*Chemistry and Industry*, April 26, 1923), whilst the nickel acquires a double negative charge, as in formula V.:—

V



In this formula there is, however, now no residual affinity left to attract the two hydrogen-nuclei to the oxygen atoms; but, since the nickel has acquired a double negative charge, there is no reason why the two hydrogen nuclei should not attach themselves directly to the metal and so make the whole of the central group of atoms electrically neutral. The final arrangement of the atoms is shown in formula VI, where the nickel is united by covalencies to 2 neutral hydrogen atoms and 4 neutral oxygen atoms.

VI

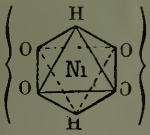


The substantial correctness of this method of representation is proved by the fact that whilst the parent glyoximes are ionisable, and interact readily with a large range of metallic salts, the dioximines are not ionisable, although the conventional formulæ, $M(O.N{:}CR.CR{:}N.OH)_2$, show them as still containing an oxime group. The hydrogen of this second oxime group cannot, however, be displaced even by alkalis; and, indeed, it is actually the custom to precipitate the dioximines in presence of an excess of ammonia, since they are even less soluble in alkaline than in acid solutions.

By way of contrast it may be noted that in the cobalt dioximines the metal is tervalent; the complex therefore acts as a univalent kation and forms a series of soluble univalent salts. The co-ordination-number of the cobaltic ion is, however, 6 and not 4; the cobaltic dioximines therefore combine with 2 molecules of ammonia, and are usually isolated in the form of complex ammines such as $[Co(O.N:CMe.CMe:N.OH)_2.2NH_3]Cl$.

As regards the spatial arrangement of the groups in nickel dioximine, it is at least likely that the 6 co-ordinated atoms are distributed round the central atom of nickel in an octahedral pattern; and, further, that the 4 oxygens occupy a plane of symmetry of the octahedron, whilst the 2 hydrogen atoms are situated at opposite apices. This arrangement is shown in formula VII, where the lines now indicate the directions of the octahedral edges instead of the bonds between the atoms.

VII



This formula is of special interest on account of the fact that we may perhaps find here a clue to the origin of the special facility with which nickel, palladium and platinum are able to bring about catalytic hydrogenation and dehydrogenation. Thus in formula VII the metal is united simultaneously to 2 atoms of hydrogen and to 4 atoms of oxygen, the latter being grouped into 2 pairs by nitrogen-carbon bridges. If these bridges were eliminated the formula might equally well be used to represent a complex, formed by the union of $Ni+H_2+2O_2$ or $Pd+H_2+2O_2$ or $Pt+H_2+2O_2$, in which the hydrogen molecules are activated by being split into two atoms, and the oxygen molecules by the opening out of their double bonds. Similar formulæ can be devised to show the simultaneous association of ethylene and hydrogen with the metal.

As Tschugaeff points out, these extremely stable dioximines belong to the general type of Peyrone's salt $[PtCl_2.2NH_3]$, with which, moreover, they agree in that the platinous dioximines yield *dibromides* analogous to the platinic ammines of the type $PtCl_4.2NH_3$, in which the bivalent metal has become quadrivalent. The dioximines, therefore, like so many other of the co-ordinated nickelous, palladous and platinous complexes, are 2 electrons short of the number required to complete the ring system of the next inert gas. The tolerance of a shortage of electrons, which was discussed in the second article of this series (*Chemistry and Industry*, March 29, 1923) appears here to become a positive preference. Thus the cupric dioximines (which contain only one electron too few) are less stable towards reagents than the corresponding nickel, palladium and platinum salts; they are also soluble in water and cannot be sublimed without decomposition even in a vacuum. Again, the zinc salts, in spite of containing the "correct" number of electrons, do not appear to form co-ordinated dioximines; at least, it has been proved that they do not interfere with the estimation of nickel by this method. In this peculiarity we appear to be face to face with a fundamental problem of atomic structure, for a solution of which we may perhaps look to the physicist, who, in his periodic classification of the elements, has at least drawn a series of rectangles, which enclose nickel, palladium and platinum, but exclude copper and zinc.

6. Summary

(*a*) The use of co-ordination compounds has provided a complete solution of the difficult problem of the separation and estimation of the metals of the transition series.

(*b*) The separations by means of carbonyls, double cyanides and double nitrites depend on the formation of complexes in which the electrons in the outer shell of the metal are made up to the number present in the next inert gas by a process of sharing electrons with co-ordinated groups.

(*c*) In the dioximines, the complex contains 2 electrons less than the number required to complete this total. These compounds are, however, remarkably stable, and can be used to effect a complete separation of nickel, palladium or platinum from other metals. The simultaneous presence of hydrogen and oxygen in the complex may perhaps afford a clue to the special value of these three metals in catalytic hydrogenation and dehydrogenation.

BRITISH FINE CHEMICALS

The British Drug Houses, Ltd., has recently issued a further catalogue, in which are listed over 3000 pure chemicals for use in research, analysis and teaching. The extensive range of rare chemicals stocked has been further increased, and inquiries are invited for any that are not included in the present list. Not only is the catalogue continually being enlarged, but we are informed that British Drug Houses, Ltd., will be pleased to purchase any reasonable quantity of new pure compounds from institutions or persons willing to co-operate in making the list more complete. Copies of tests and standards relating to the various substances listed can be supplied on request, and the firm also makes a speciality of indicators for the determination of hydrogen-ion concentration, and of preparations, such as stains, etc., for use in microscopy. Such an endeavour to make this country self-supporting in the matter of fine chemicals deserves every commendation.

LABORATORY ORGANISATION

By T. CALLAN, M.Sc., Ph.D.

The idea of a co-operative laboratory is one which in this country has not met with much support. Many progressive manufacturers and firms in a comparatively small way of business appreciate the value of a chemist, or as the authors of the book* under review would say, a scientist, thereby including the metallurgist, physicist, bacteriologist, etc., and would willingly employ one if the magnitude of their business would allow it. The co-operative laboratory idea simply means that the manufacturer or firm who cannot afford to employ, say, a whole-time chemist agrees to employ a part-time one—in other words, a group of manufacturers or firms, either representing the same interests or alternatively representing carefully-chosen non-competitive interests, guarantees the salaries and laboratory working expenses of a scientific organisation working solely for them on such problems, including and in many cases wholly consisting of, routine analyses which they submit to the laboratory. Such an organisation is in direct competition with professional analysts and technologists who are apt to see in it a diversion of work which would otherwise in part, at least, come to them. It is just such professional men, however, with whom the small manufacturer, who only makes use of scientific advice and assistance when actually compelled to, comes chiefly into contact, so that those who are in the best position to bring the co-operative laboratory idea to the small manufacturers' attention are least likely to do so.

The co-operative laboratory differs fundamentally from the Research Associations recently set up by most industries in being run on purely commercial lines. In the writer's opinion the development of such co-operative laboratories is much to be encouraged. There is no reason why every manufacturer's federation should not have its own industrial laboratory which could be made use of by every member not in a sufficiently large way of business to employ a whole-time chemist.

To the small manufacturer desirous of tentatively introducing a moderate measure of scientific control, either from conviction or by pressure of competition, the cost of providing laboratory accommodation and an adequate salary for a trained chemist is often prohibitive, so that the idea is either abandoned or a junior from the local Technical College is appointed with the dignified title of "our chemist," with inevitable subsequent disappointment. The co-operative laboratory offers another alternative and an excellent example of such an organisation is afforded by the Midland Laboratory Guild, Ltd., formed by a number of Birmingham manufacturers of brass and copper alloys, and its formation, equipment and complete organisation form the subject-matter of this exceptionally well-written volume.

These firms agreed to join with each other to establish a co-operative chemical and physical laboratory; each firm paid an entrance fee which in the aggregate was estimated to be required to equip completely the building, and further agreed to guarantee a minimum sum per annum for its upkeep. The laboratory then undertook all the work, chemical, physical and metallurgical, submitted by its constituent proprietors, the cost of running the laboratory being charged against the constituent firms proportionately to the amount of work carried out for each. The volume commences with a description of the laboratory and its equipment, and careful details are given as to arrangements of service pipes and general layout of benches, sinks, ventilation, fume chambers, etc., to ensure maximum efficiency—efficiency being measured in terms of speed and accuracy and the ability to deal with the requisite work with the smallest number of operators and a minimum cost for materials. As the authors rightly say, this standpoint from which to measure efficiency is often neglected in planning a new laboratory. It is unfortunate, however, that after the authors' earnest advocacy of efficient ventilation that *Plate I* showing the interior of the chemical laboratory should show a gas-fired combustion furnace on the open laboratory bench without hood. The authors devote considerable attention to the organisation of the laboratory, and this section of the book is well worth the attention of all who have to control industrial laboratories. They rightly say there is ample room in most of them for an improved organisation. How quickly can the figure of an analysis or the results of an investigation made a year ago be ascertained? How many tests of a certain kind have been made in a given period? What percentage of clerical errors is made? In the event of an error or dispute, how readily can the error be traced to its proper source? The answers to these and similar questions all depend on efficient organisation, and the authors' method is detailed at full length from the receipt and labelling of the sample or problem to the final report and filing of records.

A necessary corollary to an efficient system of laboratory organisation is a system of costing laboratory output; and a special chapter is devoted to this important subject. The authors' method is extremely simple and apparently effective. A standard unit determination is arbitrarily chosen, in the authors' case the volumetric determination of copper, and the relative values of other analyses or investigations are estimated against this unit as regards time spent, material consumed and skill required; thus against the unit stated, the determination of copper in white metal is worth 3 units, the saponification of an oil 2·5 units and so on, the values being adjusted as found necessary from time to time. The output of the laboratory, and indeed of each individual worker thus becomes available in terms of units of work done as well as the total capacity of the laboratory determined at some period during which the whole staff is fully engaged, so that the cost per unit is readily arrived at from the total running expenses, salaries, etc., and can then be used to give a correct allocation of costs to the proprietary firms supporting the laboratory. This system, the authors point out, is particularly well adapted to laboratories where it is essential that no profits be made, as, for example, the analytical laboratory of a large concern receiving samples from various departments where the cost of the analytical laboratory requires to be charged proportionately against those departments making use of its services. The sections dealing with laboratory equipment, organisation and costing, with an excellent chapter on the selection and training of the personnel of the laboratory, constitute about half the volume and form a most valuable contribution to subjects usually much neglected and yet on which the financial success of a commercial laboratory, whether run for profit as a private enterprise or as a co-operative organisation, largely depends. The remaining half of the book consists of a series of wholly delightful essays on the scientist in relation to this, that and the other, the mentality of the scientist, and the position of the scientist in industry, and although, strictly speaking, these have little to do with the subject covered by the title of the book the authors may readily be forgiven for having introduced them, for anyone interested in laboratory organisation cannot fail to find them extremely helpful and suggestive, and a real help in trying to see the other man's point of view, whether the other man be manufacturer or laboratory worker.

* "A Tested Method of Laboratory Organisation." By Seymour Pile, M.A., and R. Johnston. Pp.xx+98. London: H. F. & G. Witherby, 1923. Price 7s. 6d.

CHINESE OUTPUT OF GALLNUTS

Gallnuts grow in many parts of China, but the chief producing areas are in the north-west of the province of Hunan, near the Hupeh border; in Szechwan (south-east corner); in Kwangsi (north-west of Kingyuan); and on the Kweichow-Szechwan border. As in pre-war days, Germany is the largest buyer of Chinese gallnuts, followed by Japan, but exports to both countries have decreased compared with pre-war totals. The United States, Great Britain, France and Belgium are also important purchasers. Exports have decreased from 65,890 piculs in 1910, to 47,234 piculs in 1920 and 34,365 piculs in 1921. (picul=133·3 lbs.)—(*Ch. Comm. J., Mar.* 9, 1923.)

FORTHCOMING EVENTS

May 11. The Iron and Steel Institute, Annual Meeting at Great George Street, Westminster, S.W. 1, commencing at 10 a.m.

May 11. The Royal Institution of Great Britain, 21, Albemarle Street, at 9 p.m. "Gaseous Combustion at High Pressures," by Prof. W. A. Bone.

May 11. Institution of Engineering Inspection, Royal Society of Arts, John Street, W.C. 2, at 7.30 p.m. "Some Notes on 'Ciment fondu'—a Cement of High Initial Resistance—with Results of Chemical Analysis by H. F. Knight, F.I.C.," by H. J. Davey, M.B.E.

May 11. University of London, University College, Gower Street, W.C. 1. "Some Scientific Principles of Chemical Industry," by W. Macnab, F.I.C., also on May 18, at 5 p.m.

May 14. The Biochemical Society, Joint Meeting with the London Section of the Institute of Brewing, in the Engineers' Club, 39, Coventry Street, W. 1, at 7.30 p.m. (1) "Biochemical Aspect of Fermentation," by Dr. A. Slator. (2) "Physiological Aspects of Germination," by Prof. V. H. Blackman, F.R.S. (3) "Chemical Aspects of Germination," by J. L. Baker and H. F. E. Hulton.

May 14. Institution of Rubber Industry, Meeting at the Midland Hotel, Manchester. "The Scope and Progress of the Research Association," by B. D. Porritt, M.Sc.

May 14. Royal Society of Arts (Howard Lecture), at 8 p.m. "The Development of the Steam Turbine," by S. S. Cook. (Lecture 3).

May 16. The Royal Institute of Public Health. The Scarborough Congress, 1923. Among other papers the following will be read:—(1) "Ultra Microscopic Viruses," by F. W. Twort, L.R.C.P. (2) "Autolysis and Bacteriophagy," by Dr. D'Herelle. (3) "Mineral Constituents of Milk," by W. Godden, B.Sc. (4) "Dried Milk," by G. E. C. Pritchard, M.A. (5) "The Milk Problem," by H. Scurfield, M.D. (6) "Stability of Vitamins," by H. Jephcott, M.Sc. (7) "The Handling of Chemical and Bacterial Problems in Preserved Foods," by Miss C. M. Dugdale, A.I.C. (8) "Present Position of Glycosuria and Diabetes," by Prof. H. Maclean, M.D. (9) "The Influence of Atmospheric Conditions on the Health of Industrial Worker," by H. M. Vernon, M.A. (10) "Industrial Lighting," by D. R. Wilson, M.A. (11) "Industrial Dermatitis," by W. J. O'Donovan, M.D. (12) "The Causes of Fur Dermatosis," by R. P. White, M.D. The Congress continues until May 21, inclusive.

May 17. The Royal Institution of Great Britain, at 3 p.m. "Engineering Problems," by Prof. E. G. Coker.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

Again the Correspondence Columns indicate the extent to which this Journal makes its appeal. It can only be a brief space of time before advertisers realise this. Clarence Joyce's letter from America recalls one of the objects with which the Committee who were charged with the duty of bringing out this weekly paper started. It was felt that with the growth of scientific education in all schools there was a public growing up who would welcome a scientific weekly paper. A paper which, while catering for the thousands of members of the Society of Chemical Industry would appeal to the industrialist, and even to that growing mass of the public who, having had some amount of scientific training no longer yearn for the classical, the poetical, or the inane in literature. We have nothing in this country quite like the *Scientific American*, which I have read regularly for years, and which has now become so popular that it has made its appearance on the railway bookstalls. So has *Chemistry and Industry.* Some day I shall see them cheek by jowl, and then it will not be long before we see some illustrations appearing in our paper.

The German Offer which has been eagerly awaited but largely discounted before it arrived, leaves matters in the occupied areas very much where they were. As it compared unfavourably with Mr. Bonar Law's scheme which met with such little enthusiasm in France, there was little likelihood of its meeting with a better fate. Yet, in one way, it does make a tentative advance towards a settlement, it is a definite, although inadequate, offer. Such is the German way; prolonged argument always had to precede the actual doing of business. In the meantime the exchange has again been subject to violent fluctuations, and the German printing presses have been turning out paper currency at an increased rate. Little else is being exported, and the stream of dyestuffs and fine chemicals has dried up. What the end will be is difficult to foresee, but the increasing bitterness against France and England as well which is heard on all sides in Germany is indicative of the desperate condition of that country.

Japanese Dyestuff Firms according to the Special Correspondent of the *Times Trade Supplement* are going through a difficult time. There are only two companies of much substance, the Japan Dyestuff Manufacturing Company, which is the special pet of the Government, and the Mitsui Dyestuff Works under the Mitsui Mining Company. In the latter part of 1920 Japan was flooded with German dyes and the smaller companies were forced out of business. At the present time there are large stocks of German dyes in Yokohama and Kobe and although small speculative purchases of British chemicals and dyestuffs were made when the Ruhr trouble commenced, the presence of these stocks has prevented anything like a real demand on this country.

In his Third Cantor Lecture on "Nitrates from the Air" Mr. Kilburn Scott dealt mainly with the Haber process and I was interested in the particulars which he gave with reference to the progress at Billingham. Too little information has been available as to what is, perhaps, the most important plant in this country from the point of view of national safety. We are now told that for a considerable time several tons of pure ammonia have been made per day in a small plant. There has been a ready sale for this, and Messrs. Brunner Mond & Co., Ltd., hope to start producing on the manufacturing scale 120 tons of sulphate of ammonia daily some time this year. The plans, however, provide for a much larger output being made if circumstances should require it. I was very glad to hear Dr. Harker during the discussion which followed the lecture. He has made this subject peculiarly his own, but I sometimes wish I could hear his case stated by someone else. I have a feeling there is more in it than he sometimes makes it appear. Mr. Scott's reply to the discussion included one complaint which I have voiced in this column already. He said we were very fine fellows, but that we lacked the habit of working together. Very true. We are better than we were, but there is still lots of room for improvement in this direction.

The Dyers' Company during the past few weeks has added to the number of its liverymen three persons who have in different ways some knowledge of the position of dyestuffs in this country. Sir William Alexander, of the British Dyestuffs Corporation, will bring with him the prestige and knowledge which his position as Chairman of the Corporation gives him. Mr. Sutcliffe Smith of the Bradford Dyers' Association, as Chairman of the Colour Users' Association, has played a very important part in guiding a somewhat intractable body of men. That he has been successful, places him in the front rank of those who are called "tactful." You need to be honest if you would succeed in a post of that kind. Mr. Woolcock was no doubt included by reason of his Chairmanship of the Development Committee under the Dyestuffs Acts.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL MEETING

Cambridge, June 20 to 23, 1923

The following is the programme of arrangements, of which a full account has been sent to every member of the Society :—

Wednesday, June 20. 8.30 p.m. Smoking Concert (place to be announced later).

Thursday, June 21. 10 a.m. Council Meeting in the Arts School, Bene't Street. 11 a.m. Welcome by the Vice-Chancellor of the University (Rev. E. C. Pearce, D.D.) in the Arts School. Annual General Meeting of the Society. Address by the President, Dr. E. F. Armstrong, F.R.S. During the afternoon there will be visits to Gardens and Colleges, Boating, Tennis, etc. 5 p.m. Reception by the Vice-Chancellor of the University in the Fitzwilliam Museum, where tea will be provided. 9 p.m.—2 a.m. Reception in the Guildhall by the President and Mrs. Armstrong, to be followed by a Dance.

Friday, June 22.—11 a.m. Presentation of the Society's Medal to C. C. Carpenter, Esq., C.B.E., D.Sc., M.Inst.C.E., in the Arts School. Address by Dr. Carpenter. About 2.30 p.m. Address by Dr. F. W. Aston, F.R.S., on " Isotopes," in the Arts School. Garden Party at Sidney Sussex College. Tea will be served during the afternoon in the gardens (in the Hall, if wet). 7.30 p.m. Annual Dinner of the Society in the Hall of Trinity College, at which a large number of Cambridge guests will, it is hoped, be present.

Saturday, June 23.—Charabanc trip to Ely and its Cathedral, returning to Cambridge in the afternoon. The party should set out about 10 a.m., but the precise time of leaving will be intimated later. Lunch will be served at Ely.

The office of the Society during the Annual Meetings will be at the Arts School, Bene't Street. It has been decided on this occasion to charge an inclusive fee of £1 10s., in return for which a member will be supplied with a ticket for each of the functions, including the Dinner (inclusive of wines), the Dance, the trip to Ely and the lunch there. Tickets for ladies and members' guests are also £1 10s. each.

In addition to hotel accommodation, hospitality will be offered by several Cambridge hostesses to members accompanied by their wives or daughters, and to lady members, and single men accommodated in college rooms. The following Colleges have already agreed to offer accommodation : King's, Magdalene, Pembroke, Downing and Jesus, from Wednesday, June 20 ; Trinity College from Thursday, June 21. Members intending to be present at the Annual Meeting should arrange for their accommodation without delay. All communications regarding this should be sent either to the General Secretary in London (up to May 30), or to Mr. J. E. G. Harris, University Chemical Laboratory, Downing Street, Cambridge, stating whether the member desires : (1) hospitality ; (2) accommodation at one of the Colleges ; or (3) hotel accommodation. In each case information should be supplied as to whether or not the member will be accompanied by friends, and in the former case the names and addresses of these should be given.

A Ladies' Committee, of which Mrs. Weekes, wife of the Master of Sidney Sussex College, is Chairman, and of which Mrs. W. H. Mills and Mrs. Oliver Prior are Secretaries, has been formed to look after the interests of ladies attending the meetings. Mrs. C. T. Heycock is arranging for tennis in gardens and colleges, and for boating. Ladies are eligible to attend the meetings, including the Smoking Concert, the Dinner, the Dance, and the Excursion to Ely.

J. P. Longstaff,
General Secretary

Central House,
Finsbury Square,
London, E.C. 2

NEWS FROM THE SECTIONS

OTTAWA SECTION

Mr. F. J. Hambly occupied the chair at the meeting held on April 12 at the University Club, Elgin Street, Ottawa. After the minutes of the previous meeting had been read and approved, Dr. Tingle reported that suggested amendments to the Bill relating to Patents of Invention had been sent to the Minister of Trade and Commerce. The Secretary said that several more papers were nearly ready for publication, and that the committee felt that such papers should receive a far greater circulation. It was suggested that a Papers Committee of about ten members should be appointed next year.

Mr. R. J. Traill, research chemist of the Ore Dressing and Metallurgical Division of the Mines Branch, then read a paper on " Electrolytic Iron," in which he traced the development of the electrolytic production of iron from the beginning. Electrolytic refining of iron was at present an infant industry, but electrolytic refining was well established for the treatment of other metals such as zinc, copper, etc. The production of pure iron by electrolysis had been known for over 70 years, but not until the last ten or fifteen years, when the unusual physical and chemical properties of electrolytic iron were realised, was real interest taken in its production. The work of various investigators in this field was discussed and special attention was paid to the Eustis process, which is applicable to the direct treatment of ores, particularly pyrrhotite and iron pyrite ores, and for the recovery of sulphur as a by-product, as well as copper, lead, zinc, gold and silver, when these are present. Such a process was of particular importance for Canada, which had large resources in pyrrhotites and iron pyrites, many of these containing valuable metals, present, however, in insufficient quantities to make the deposits workable for these metals alone, but worthy of recovering as by-products in the production of electrolytic iron. The author then described some preliminary tests made to investigate the process from the point of view of utilising Canadian ores. In conclusion Mr. Traill outlined various uses of electrolytic iron, such as electrical machinery and appliances, liquid containers, pipes, wire, parts to be galvanised or nickel-plated, kitchen utensils, etc.

MANCHESTER SECTION

The eighth meeting of the Manchester Section was held on May 4, Dr. E. Ardern, F.I.C., being in the chair.

Mr. Howard Cheetham read a paper entitled "Reflections on Patents," in which he briefly discussed the history of English Patent Law, the effect of the conditions in which it began on judicial and public opinion regarding the protection of inventions and discoveries, and drew attention to the suggestions now being made in France for the better reward of scientific workers.

The second paper, by Messrs. F. S. Sinnatt, A. B. Owles and N. Simpkin, was entitled: "The Inorganic Constituents of Coal," Part 4, "The Melting Point of Coal Ash." Mr. Sinnatt, in reading the paper, explained that it was chiefly concerned with the description of a method of determining the melting point of ash, and an examination of the melting point of the various ingredients which could be separated from coal seams. The term melting point had been adopted to describe the complete melting of the ash, whilst the softening point was the temperature at which the first signs of softening occurred. The literature on the subject was reviewed, and an apparatus devised by the authors for the purpose of their experiments was exhibited. It was shown that there were wide variations in the melting point of ash from coal in different portions of the same seam.

A paper entitled "The Behaviour of the Principal Celluloses Towards Iodine and Dyestuffs," by Messrs. J. Huebner and J. H. Sinha, was read by Mr. Huebner. It was shown that different celluloses absorbed dyestuffs in very varying proportions, that the problem was one of considerable complexity, and that celluloses were not such simple bodies as they were frequently supposed to be. Although they had the same chemical formulæ they were entirely different, and differed very materially in their behaviour towards chemical reagents. It was not beyond possibility that the lengths and diameters of the fibres had something to do with the absorption of dyestuffs and of iodine.

LIVERPOOL SECTION

The annual meeting was held in the Muspratt Lecture Theatre of the University of Liverpool, on April 27, Professor E. C. C. Baly, F.R.S., in the chair. The following elections were made for the Session 1923-4:—Chairman, Mr. Edwin Thompson; Vice-Chairman, Dr. G. C. Clayton, M.P.; Hon. Treasurer, Dr. Alfred Holt; Hon. Secretary, Mr. E. Gabriel Jones. Four vacancies on the Committee were filled by the election of Dr. H. A. Auden, Captain F. W. Bain, Col. E. Briggs, and Dr. C. H. Clarke. The Secretary then submitted a report on the work of the past Session.

Mr. W. Ramsay, F.I.C., read a "Note on Petroleum." He had found a small quantity of nickel in crude Mexican oil, and this led him to examine specimens of petroleum from different parts of the world; in all cases except one—a refined ozokerite—the presence of nickel was demonstrated, the amounts varying from one part to over 200 parts per million. Sabatier and Senderens had produced artificial petroleum oils by hydrogenating acetylene at high temperatures and pressures and had suggested that natural petroleums were formed in the interior of the earth by some such hydrogenation process. Carbon, carbon monoxide, and carbon dioxide could be hydrogenated to form methane at comparatively low pressures and temperatures, and the author's results led to the conclusion that the theory of Sabatier and Senderens might possibly be the correct explanation of the origin of petroleum, the nickel found being the catalyst by the help of which the reactions have proceeded. An attempt was made to ascertain the condition in which the nickel was present in the oil, but this proved unsuccessful; the author, however, came to the conclusion that the metal was either in solution in the oil, or, more probably, in a colloidal form or fine suspension.

A paper on the "Determination of Sulphur" was read by Mr. J. M. Taylor, F.I.C., who said that, to determine sulphur, it was almost invariably converted into sulphuric acid or a sulphate and precipitated as barium sulphate. Variations in the conditions of acidity, method of addition of barium chloride, nature of other salts present and concentration of the solution, affected the purity of the barium sulphate. The best conditions for the determination of sulphur had been investigated by Lunge, Pattinson and others, but there appeared to be room for further work, as differences of over 1 per cent. in the sulphur content of pyrites, for example, were frequently found. Tables showing the variation of the barium sulphate obtained by employing different methods of adding barium chloride were shown. A higher degree of acidity during the precipitation of barium sulphate seemed to give more accurate results; in addition, the precipitate was obtained in a crystalline form, so that it settled and washed much more quickly than when precipitated in a slightly acid solution, as generally suggested. To obtain a still purer form of barium sulphate it was necessary to add the barium chloride and the sulphate simultaneously to boiling water acidified by hydrochloric acid, with constant stirring. This was equivalent to the precipitation of extremely dilute solutions of sulphuric acid by equally dilute solutions of barium chloride.

Precipitated in this manner, a heavy, distinctly crystalline barium sulphate was formed, which was practically pure, and could be washed readily and filtered perfectly through a single paper. The principle of adding two soluble salts simultaneously, so as to obtain a purer salt in larger crystals, was capable of a wide application. This principle was employed during the war to obtain explosives in a purer form, and by its use a crystalline form of calcium carbonate was obtained which could be treated on a mechanical filter, thus securing a larger output. In conclusion, methods of analysis formulated at the Central Laboratory, Widnes, for some of the new compounds now prepared in this country, including sulphur mono and di-chloride, thionyl chloride, chlorsulphonic acid and leucotrope were described.

CHEMICAL ENGINEERING GROUP

The Fourth Annual Meeting and Dinner was held at the Engineers' Club, London, on May 4, Mr. J. Arthur Reavell presiding. After the minutes of the third annual general meeting had been confirmed, the Hon. Secretary, Mr. H. Talbot, presented his report on the work of the year. The work of the committee of the Group during the past year consisted mainly in strengthening the organisation of the Group, particularly in reference to its relations with the parent Society, and in an endeavour to secure its continued well-being, rather than in active propaganda work by means of meetings, conferences and the like. This course was due largely to financial reasons, as the deficit on the previous year's working had persisted during the past year. The Data Sheet Committee had continued its labours, which had temporarily been suspended owing to lack of funds. Two data sheets, "The Properties of Tan Extract Liquors" and "Condensation Curves for Hydrochloric Acid," had been issued, owing to the receipt of a special grant of £100 from the Messel Memorial Fund of the Society. After expressing regret at the resignation from the Group Committee of Dr. H. J. Bush, who assisted in the inauguration of the Group and had done extremely valuable work on the Committee ever since, reference was made to the relations between the Group and the parent Society, which had continued to be the subject of much negotiation and discussion during the past year, following the preliminary agreement arrived at and reported to the last annual general meeting. The Hon. Secretary said it was impossible to overrate the services rendered to the Group by the Chairman, Mr. J. A. Reavell, and the Hon. Treasurer, Mr. F. H. Rogers, on the one hand, and by Dr. Armstrong, President of the Society, and Mr. E. V. Evans, Hon. Treasurer of the Society, on the other. As a result, the feeling between the two bodies had never been more cordial and, as evidence of this, the Group had been entrusted with the whole of the organisation of the Chemical Section of the World Power Conference to take place at the opening of the British Empire Exhibition during 1924. Similarly, the relations between the Group and the Institution of Chemical Engineers was naturally extremely close and joint offices were now shared in Abbey House, Westminster. The future position between the two bodies was still the subject of negotiations, and the Group Committee feels that in everybody's interests the two organisations cannot be too closely allied. Reference was then made to the various meetings held during the year, and regret expressed that the membership of the Group had declined from 401 to 315 at the end of the year, though the latter number had since considerably increased. As a result of the decrease in membership during the year, the revenue of the Group suffered, but the Society agreed to meet the deficiency on the past two years, amounting to £173, and special thanks were recorded to the Society for its generosity. At the beginning of 1922 an American Section of the Group was inaugurated, which continued in existence, although the organisation initially developed for its work might have to be revised, in view of the new relations between the Group and the Society. As one consequence of the formation of the American Section, the Committee nominated Dr. Ruttan, a past-president of the Society, as the first honorary member of the Group, a compliment which Dr. Ruttan had accepted. In conclusion, the past year had seen a very definite increase in the Group's stability, and it was anticipated that with the financial arrangements now made, the Group would be able to do much more useful work in the future than was possible in the past. The Hon. Secretary's report was adopted without discussion.

Mr. F. H. Rogers, Hon. Treasurer, in his report, said the falling off in membership during the year was due not to lack of interest in the work of the Group but to the trade slump. The arrangements by which the Society now collected the subscriptions of the members of the Group had brought in more members, so that the position now was more satisfactory, and the Group started the current year free of debt. There had been some discussion as to whether an appeal should be made to the members of the Group for donations, but it had been thought wise not to do that. Had such an appeal been made he was sure it would have met with a very good response, but after discussion with the parent Society it was arranged that the deficit should be borne by the Society. The Hon. Treasurer's report and the balance-sheet were adopted.

New rules for the Group were then adopted, consisting of certain modifications of the existing rules, based on those of the London Section, the working of which was slightly different from the working of the Group. The new rules were adopted, subject to confirmation by the Council of the Society.

With regard to members of Council for the coming year, the Hon. Secretary reported that there had been no nominations, and he therefore suggested that the existing members of Council should be re-elected. This was agreed to, and the present Chairman, Mr. J. A. Reavell, Hon. Treasurer, Mr. F. H. Rogers, and Hon. Secretary, Mr. H. Talbot, were also re-elected.

On the motion of Mr. Rogers, a hearty vote of thanks was accorded to the parent Society, special reference being made to Mr. E. V. Evans, the Hon. Treasurer of the parent Society, for the manner in which he had supported the Group in regard to financial assistance.

Prof. J. H. Hinchley, proposing a vote of thanks to the Chairman, Hon. Treasurer and Hon. Secretary, said that only those who were behind the scenes knew the amount of work actually done by these three gentlemen. He felt that the Group was now soundly established, and this was largely due to the work of these three gentlemen.

The only toast at the subsequent dinner was "The King," the rest of the evening being spent in listening to an interesting musical programme.

MEETINGS OF OTHER SOCIETIES

INSTITUTE OF METALS

The Thirteenth Annual May Lecture was delivered on May 2, by Dr. W. Rosenhain, F.R.S., of the National Physical Laboratory, the subject being the "Structure of Alloys." Referring to the great accumulation of facts relating to the properties and microstructure of alloys during recent years, the lecturer said that the time had arrived when it was most desirable that a key should be found to this maze of knowledge in the form of a general theory that would link together the mass of facts into a homogeneous whole. Such a theory he attempted to put forward, basing it upon the intimate knowledge of crystal structure which had recently been acquired by means of the application of X-rays to the study of the arrangement of atoms in crystals. The crystal structures found in pure metals became modified in the case of alloys, particularly in those called solid solutions, where a second kind of atom, the atom of the alloying element, entered into the structure of the crystal and produced in it certain minute changes. With regard to such changes, the lecturer put forward two simple principles, and was then able to show a striking series of inferences from his theory, which accorded closely with a large number of experimental facts. Connexions between various series of properties in metals and their alloys were established which had not formerly been recognised, such as the relation between hardness and alloying power. Especially important was the connexion between the minute distortion of crystal structure which occurred in alloys and their behaviour on melting and freezing, whilst such phenomena as plasticity, diffusion and others fell easily into line with the same type of explanation. Most important of all, perhaps, was the fact that this new theory of alloy structure afforded a ready explanation of the electrical properties of metals and alloys and the changes of those properties when the metal was heated or cooled. These explanations covered the mysterious phenomena of super-conductivity found in many metals when cooled nearly to the absolute zero of temperature.

THE ROYAL SOCIETY

The following are abstracts of communications made to the Royal Society by Prof. H. E. Armstrong, F.R.S., on May 10 :—

I. The Origin of Osmotic Effects. IV. Hydrono-dynamic Change in Aqueous Solutions.—The conclusions arrived at are summarised in the following propositions :—

1. "Water" is a complex saturated with the gas *Hydrone*, OH_2. Primarily, hydrone is the sole potentially "active" constituent, but it becomes actually active only under conditions which suffice to determine electrolytic change.

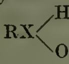
2. The vapour pressure either of water or of a solution is the measure of the proportion of free hydrone molecules present in the liquid.

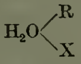
3. Although the vapour pressure is lowered in presence of any solute, the solution acquires attractive properties. The internal activity is increased whilst external activity is diminished.

4. The effect produced may be ascribed to an interaction of molecules of the solute and those of hydrone. From non-electrolytes (under the influence of conducting impurity) a simple hydrol is formed,  $M\begin{smallmatrix}/ H \\ \backslash OH\end{smallmatrix}$, only a single molecule of hydrone being "distributed" upon the molecule of the solute, whatever its magnitude.

5. In the case of potential electrolytes, a reciprocal interchange of radicles of salt and hydrone is to be postulated. Not only is the

solute hydrolated, but it is distributed upon hydrone, the salt X′R′ giving rise initially to the reciprocal systems



$RX{<}{}^{H}_{OH}$ and


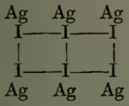
$H_2O{<}{}^{R}_{X}$

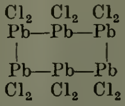
6. As the concentration is lowered, under the influence of hydrone, the complex  $RX{<}{}^{H}_{OH}$ is more and more converted into *hydronol*,  $H_2O{<}{}^{OH}_{H}$. Ultimately, the solution contains the solute only in the form  $H_2O{<}{}^{R}_{X}$ *together with an equal number of molecules of hydronol.*

7. The "distributed" reciprocal complexes, including hydronol, are the electro-chemical agents in a solution. The negative radicle in such complexes has greater residual affinity than it has in the original simple molecules.

8. The osmotic pressure manifest in an aqueous solution is the pressure exercised by the extra molecules of hydrone attracted into it by the "distributed" complexes, one by each complex, acting as though they were present in the gaseous state. In short, osmotic pressure developed within an aqueous solution, whatever the solute, has its origin in one and the same cause, and is properly spoken of as *hydrodynamic*—if the word be permissible: indeed, this term may be used as expressive of the general activity of water, *electro-chemical and osmotic.*

II. Electrolytic Conduction: Sequel to an Attempt (1886) *to Apply a Theory of Residual Affinity.*—Referring to the distinction which he drew in 1886 between simple and composite electrolytes—the former being electrolytes *per se*, the latter solutions of "salts"—the author calls attention to the diverse behaviour of the silver and lead haloids on electrolysis; the current being carried, as it were, by the metallic ion of the silver and by the halogen of the lead compound. The conclusion is drawn that the salts of the two metals differ in structure—perhaps thus





The assumption is made that the primarily active unit is the fundamental molecule, and that the circuit is formed by these molecules being coupled with (distributed at) the electrode face and with the complex molecules. A similar interpretation is applied to aqueous solutions.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

The Fuel Group of the Société met on April 25, under the presidency of Monsieur R. Etienne, professor at the National Higher School of Mines and vice-president of the Société, to discuss the terminology of liquid fuels. The necessity for defining the meaning attached in each country to the term "liquid fuel" had already been recognised by the International Union of Pure and Applied Chemistry, and by the congress on liquid fuels, held in October, 1922. Once this definition was established it was essential to prepare a list of the terms employed in each country to designate the various fuels and to complete this list by adding the chemical and physical characters of each fuel, and also the methods employed for determining these characters. It was therefore thought useful, in view of the approaching meeting at Cambridge of the International Union of Pure and Applied Chemistry to consult all those interested in the question, and it was decided to draw up, within three weeks, the list required, such list to be considered and discussed by an open commission. All the associations of producers and consumers have already undertaken to co-operate, so that the French delegation will have a very complete list to present. The question of the standardisation of terminology and analytical methods was also touched upon, but was referred for future discussion.

FEDERAL COUNCIL FOR PURE AND APPLIED CHEMISTRY

This Council consists of representatives from the Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, and nearly a score of other societies and associations. It has two main functions: 1, to act as the British organisation of the Union Internationale de la Chimie Pure et Appliquée; 2, to provide some sort of co-ordination between the various chemical societies of this country. Sir William Pope is the President. During the year 1922 the Federal Council assisted in the meeting of the Union Internationale held at Lyons, and was helpful in connexion with the effort to provide a weekly chemical journal to include both pure and applied chemistry. A number of other matters also came before the Council for consideration. Its income was £200, provided equally by the Chemical Society and the Society of Chemical Industry. Its only expense was the payment to the Union Internationale of 4500 francs for the year 1921, and 4500 francs for the year 1922. The Council incurred no office expenses during the year 1922, but will incur some expense this year in circulating the appeal for its fund, a note of which appears elsewhere in this issue.

CORRESPONDENCE

THE TITLE "CHEMIST"

Sir,—The Council of the British Association of Chemists wishes to endorse fully through your columns the proposals of Dr. E. F. Armstrong, set forth in his letter of April 9, for the calling of a round-table conference to discuss with the pharmacists the possibility of agreement over the future employment of the term "chemist."

The question of the education of the public mind in the correct signification of the terms "chemist" and "pharmacist" is one which has received the continuous attention of this Association, and it is felt that the calling together of such a conference as Dr. Armstrong proposes, representative of the interests concerned, would, with the active support of the press, tend in large measure to dissipate the confusion of thought at present existing in the mind of the general public.

If Dr. Armstrong will undertake further steps in the matter, we feel, that in addition to securing the immediate support of this Association, he will carry with him the whole of the other chemical societies.—We are, Sir, etc.,

for The British Association of Chemists
Herbert Levinstein, *President*
J. W. Hinchley, *Past President*
Wm. E. Kay, *Chairman of Council*
I. Boodson, *Hon. General Secretary*

108, Baker Street, W. 1
May 4, 1923

THE NITROGEN INDUSTRY

Sir,—My friend, Prof. Partington, in commenting on my review of the book by Dr. Parker and himself on "The Nitrogen Industry," appears to think that I have been a little unfair in my criticism, and that my words suggest that the volume is "written round the Report of the Nitrogen Products Committee." He considers that the parallel I gave of Mr. and Mrs. Sidney Webb's books in their relation to the Minority Report on the Poor Law is inapplicable.

But, Sir, I was careful to point out in my review, that although extensive use was made of the Committee's Report, in which the principal stress was laid on the *economics* of the various processes, the authors give "more detailed descriptions of the *processes themselves*," with illustrations of plant employed, and of a number of nitrogen factories. As in the one case there is no lack of the individuality of Mr. and Mrs. Webb, so in the other there is plenty of Partington and Parker unhesitatingly expressed. My remarks certainly did not imply want of originality in the volume in question.

I might mention that it seems unfortunate that although about 4000 copies in all of the Report of the Nitrogen Products Committee were issued, it has now been allowed to go out of print, although I know from the numerous inquiries which have reached me since I resigned from Government service, that there is still a demand for the Report, now very difficult to obtain.

I stated previously that I agree to a great extent with Prof. Partington in his criticisms as to the lack of a vigorous and definite Government policy in this country on nitrogen matters. In my view this was in large measure due to the constant changes taking place in the higher personnel of the Ministry of Munitions. As soon as a certain measure of educational work as to the aims of the Nitrogen Products Committee had been accomplished, and the interest had been aroused of officials dealing with the various branches, the officials were transferred to other duties, and the process had to be recommenced. The initial steps which led up to the formation of the Committee were taken by the Council of the Faraday Society in 1916, during the *régime* of the first Minister, Mr. Lloyd George, whilst the dissolution of the Committee and the sale of the Billingham factory took place under the fifth and last minister, Lord Inverforth.

If I wished, I might take a leaf out of the book of certain politicians, and set forth some of the inner history of what actually happened. I have, however, at present no intention of so doing, although some of the story might have to be even more startling than the statements of Prof. Partington.—I am, Sir, etc.,

J. A. Harker

16, Victoria Street, S.W. 1
May 5, 1923

BRITISH ASSOCIATION OF CHEMISTS

Dear Sir,—My attention has been called to the statement in the editorial of your issue of April 27, that the National Union of Scientific Workers has absorbed, or has been absorbed by the British Association of Chemists. In the interests of accuracy, I wish to inform your readers that neither version is correct, and that the National Union of Scientific Workers and the British Association of Chemists are still separate entities, working quite independently of each other.

During the past year negotiations have been in progress between the two Associations with a view to co-operation on matters of definitely common interest, and with the further object of avoiding overlapping of work. How far the proposals at present under consideration will lead to closer working between the two Associations it is not possible to state, but for the present no alteration in the constitution of the Association is contemplated by the Council of the British Association of Chemists.—I am, Sir, etc.,

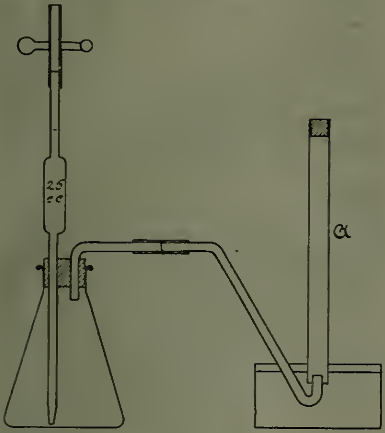
I. Boodson,
Hon. General Secretary

108, Baker Street, W.1.
May 3, 1923

DETERMINATION OF EQUIVALENTS

Sir,—The following may interest some of your readers, especially as I have not seen such an apparatus described in any of the elementary textbooks on chemistry.

A simple apparatus for carrying out this determination suitable for practical work in elementary classes is shown in the annexed sketch, which needs little explanation. The apparatus has the merit of being easily accessible in most schools, and the use of graduated measuring tubes is dispensed with. The tube A is a piece of combustion or other wide glass tubing of uniform bore, 2-3 cm. in diameter, and 45–50 cm. in length. In use, the length from the end to the bottom of the cork is measured (l cm.) and the volume (y c.c.) found by filling it with water from a graduated measure. It is then inverted over the end of the delivery tube and 25 c.c. of acid run into the flask from the pipette. When all the metal has dissolved, the level of the water inside the tube is adjusted to that of the water in the trough, and the length of the space occupied by the gas is measured (d cm.). The volume of hydrogen displaced by the weight of metal taken is therefore



$$\frac{d \times y}{l} - 25 \text{ c.c.}$$

The equivalent is calculated in the usual manner, after reducing this volume to N.T.P. Results very close to the correct figure can be obtained by careful students. The amount of metal taken should be such as will give about 100 c.c. of hydrogen (about 0·1 g. in the case of magnesium).—I am, Sir, etc.,

A. O. Jones

Technical College, Huddersfield

NEWS AND NOTES

FRANCE

The Title "Chemist"

The discussion on the correct use of the title "chemist" in Great Britain has attracted notice also in France, where a similar problem already exists. The wrongful use of the titles "chemical engineer" and "chemist" is strongly opposed by true chemists and pharmacists, who agree perfectly on the matter, but at present anybody in France can employ the titles, The word "engineer" designates a profession open to anyone and is not a title recognised and protected by the law. The use of the name "lawyer" (avocat) is legally restricted, but no penalties are imposed for improper use, and the titles of "médecin" and "pharmacien," which justly represent a certain status, can be freely used. It is true that persons who follow the profession of physician or pharmacist must be legally qualified, but the mere use of the title incurs no risk and the same is true of all diplomas and University degrees. Such a state of affairs is obviously very prejudicial to true chemical engineers and chemists, whose professional skill has been acquired through long years of study and practice, crowned by a diploma, and who yet have to meet the competition of persons without qualifications or assured technical and scientific knowledge. The only titles protected in France are those of "ingénieur agronome" and "ingénieur agricole." It is true that a certain selection of true chemists, chemical engineers and pharmacists is made by the regulations for admission into the various scientific societies, such as the French Chemical Society, the French Society of Industrial Chemistry, etc., and by professional societies comparable with the British Institute of Chemistry, but it has no legal force. In addition, a definition is badly wanted of the titles "chemical engineer" and "chemist," such definition to include the diploma-bearing students of the various schools and institutes of chemistry of the various Universities or technical schools, and also those who, by their long period of practice, though bearing no diplomas, belong to the profession. The position has, however, been the subject of numerous discussions, which have led to recommendations synthesised in two Bills which are to be presented to the Chamber of Deputies. One Bill proposes to complete the article 259 of the Penal Code by a clause providing imprisonment for from six days to two months and fines of from 100 to 200 francs for those who wrongfully utilise a professional title, a university degree, or a diploma of a public institution. The second Bill restricts the use of a professional title to those who have fulfilled certain conditions and provides penalties for those who use such titles without due authorisation. Thus the question of protecting the title of "chemical engineer" and consequently that of " chemist " (professor, industrial chemist research chemist, analyst) seems to be progressing favourably in France and is being enquired into by the Higher Council for Technical Education.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Electric Energy (Coal Consumption)

In a written answer to Mr. Hardie, Col. Ashley said that during the year ending March 31, 1922, the lowest consumption of coal per unit of electricity generated at public supply stations in Great Britain was 1·7 lb. The returns for the year ending March 31, 1923, were not yet complete.—(Apr. 30.)

Safeguarding of Industries Act, Part II

Viscount Wolmer, in answer to Mr. Tubbs, said that the number of industries affected by Orders made under Part II of the Act was seven. An exact figure of the number of employees in these industries could not be given.—(May 1.)

Home-Grown Sugar, Ltd.

In reply to Mr. Barnes, Major Barnston said that the value of the 250,000 £1 shares in Home-Grown Sugar Ltd. had been written down, in common with shares held by the public, to 5s., so that the nominal value of the Government shares was now £62,500.—(May 1.)

Industrial Diseases

Mr. Bridgeman informed Mr. Hancock that the number of industrial diseases notified under the Factory and Workshops Act was 514, including 38 fatal, in 1920; 350, including 32 fatal, in 1921, and 410, including 35 fatal, in 1922.—(May 2.)

Colonial Grown Sugar

In a written answer Mr. Ormsby-Gore informed Captain Terrell that the Colonial Secretary was anxious that as large a proportion as possible of this country's sugar requirements should be produced on British Territory, and hoped that the preference of British grown sugar would increase that proportion. The Colonial Office constantly placed the best scientific and technical advice at the disposal of sugar-growing colonies through the local departments of agriculture, but it would be beyond the functions of the Colonial Office or of the Colonial Governments to attempt to influence planters in choosing crops to be grown.—(May 2.)

HOUSE OF LORDS

Smoke Abatement

Answering Lord Newton, the Earl of Onslow stated that a Smoke Abatement Bill was to be introduced this session by the Government.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for May* 3)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Albania	Pharmaceutical and medicinal materials	569
Algeria	Earthenware, glassware, sugar	586
Argentina	Hardware, red lead, rubber tubing	589
,,	Perfumery,	590
Belgium, Netherlands & Northern France	Non-ferrous metals	570
British India	Electric cable (tender)	*
Bulgaria	Zinc chloride, creosote, caustic soda, copper sulphate, colza and mineral oils, tin, lead, pig iron and quinine	571
Canada	Stainless steel tubing	563
Denmark	Tin, zinc, lead, antimony moulders' requisites	572
France	Insulating materials, metallurgical products, sheet iron, sheet tin, steels, rustless steels	575
India, Burma and Ceylon	Brass and copper sheets and tubes	568
Italy	Electrical materials, iron, cement	577
Italy (Fiume)	Tinplate	578
Morocco	Holloware	853/6/F.G. E.C./A./2
Rumania	Drugs and chemicals	10543/F.E. (C.C./2)
Rumania (Transylvania)	Flake litharge, red lead	583
United States	Asbestos lumber	588

* The Director-General, India Store Dept., Branch No. 10, Belvedere Road, S.E.1.

TARIFF CUSTOMS EXCISE

Angola (*Portuguese West Africa*).—All disinfectants and insecticides can be imported duty free.

Austria.—Modifications have been made in the duty levied on imports of olive oil and potato starch.

Denmark.—Revised duties have been applied as follows :—Vanilla, vanillin and saffron, 20 kr. per kg., tyre covers, 40 öre per kg., plus 6 per cent. *ad valorem*, inner tubes, 12 öre per kg., plus 6 per cent. *ad valorem;* aluminium wares, 45 öre per kg. ; porcelain, 65 öre per kg.

French Togoland.—Restrictions have been placed on the sale and importation of drugs, chemical and medicinal products, pharmaceutical and druggists' specialities, and especially on opium, morphine, cocaine and other poisonous substances.

New Caledonia (*French*).—Import duties have been removed from molasses and ammonium sulphate.

St. Vincent.—A restriction has been placed on the importation of raw and medicinal opium, morphine, heroin, cocaine and similar drugs.

South Africa.—In the issue for May 3 a schedule is given, setting forth proposed dumping duties on various goods, including detonators, calcium carbide, motor spirit, paper, rubber, asbestos-cement manufactures, metal sheets, paint, etc. The Budget proposes to amend the excise tariffs on patent medicines and perfumery.

Tunis.—The prohibition on the export and re-export of molasses has been reimposed.

Uruguay.—Bicarbonate of soda of a strength exceeding 98 per cent. is to be classed as "medicinal," and of a strength less than 98 per cent., under "commercial." Bicarbonates in packets or cases labelled "pure" may be imported provided they are of a strength of more than 98 per cent.

Jugoslavia.—The export duty on tanned ox and calf leather, and edible oils has been reduced.

PERSONALIA

The following have passed the examination for the Associateship of the Institute of Chemistry :—P. J. Brady, H. J. Grayson, L. W. Gregory, G. Loasby, B.Sc., L. W. Marrison, H. W. V. Player, D. A. Smith, and G. J. C. Vineall, B.Sc.

Mr. A. J. Hoskins has been appointed professor of mining in the University of Illinois in succession to the late Dr. H. H. Stoek, and Prof. E. O'Neill has resigned from the chair of inorganic chemistry in the University of California.

Dr. M. Perard has been appointed Professor of Agriculture and Organic Chemistry at the Central School of Arts and Manufactures, Paris.

* * *

The death is announced of Monsieur Joseph Gillet, an industrialist of Lyon, whose name is well-known in various branches of the silk, chemical, textile and dyeing industries.

REVIEWS

Surface Tension and Surface Energy and Their Influence on Chemical Phenomena. *By* R. S. Willows *and* E. Hatschek. *Third edition. Pp.* 136. *London: J. and A. Churchill,* 1923. *Price* 6*s.* 6*d.*

This edition, prepared by Dr. Willows, is nearly twice the size of the first edition which appeared in 1915, and has been brought carefully up to date. The chief enlargements comprise an account of the important recent work of such investigators as Langmuir and Hardy on the properties of thin films, polarised molecules, and lubrication.

A clear and reasoned account is given of the main aspects of the subject, and its brief treatment is quite comprehensive. The book can be heartily recommended to those who wish to become acquainted with the essentials in this rapidly widening field, which interests biologists, physicists and chemists alike.

J. W. McBain

Dr. Aetherische Olien Leverende Planten van Nederlandsch Oost-Indië en de Bereiding van haar Oliën. *By* A. W. K. de Jong. *Pp. vii*+183. *Amsterdam: Koloniaal Institut,* 1922. *Price* 3·60 *florins.*

This publication, reprinted from the *Indische Mercuur* of 1922, and issued by the Dutch Colonial Institute, consists of a series of monographs edited by A. W. K. de Jong, on the methods of distillation in general use, in reference to their application to those oils distilled in the Dutch Colonies, and to the extraction of perfumes generally. In the description of distilling processes, with a number of photographic illustrations, there is nothing new ; it is merely a summary included for the sake of convenience to readers.

Useful summaries of the various commercial aspects of production of the oils of citronella, lemongrass, palmarosa, vetivert, patchouli, basil, chenopodium, cinnamon, clove, pimento, nutmeg, cubebs and a number of others are included.

The chemistry of the oils is but sparingly mentioned, and the brochure must be regarded as a useful catalogue of domestic rather than general interest, although it contains much useful information of a botanical and commercial nature, carefully summarised, and of value to the essential-oil specialist.

Ernest J. Parry

Mr. H. G. Byers has been elected president, and Mr. L. van Doren vice-president of the American Institute of Chemistry for 1923–24.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The general demand for chemicals is quite up to expectation and on the whole prices are fully maintained. Saltcake shows greater activity and available supplies in quantities for export in large parcels are getting scarce. Bleaching Powder is slightly better and Acetic Acid still in good demand and short supply. There is good inquiry for both home and export for Alkali and Caustic Soda.

Acetic Acid, 40% tech.	£24 per ton.
Acid Hydrochloric	4s.-5s. per carboy d/d.
Acid Nitric 80° Tw.	£24 10s. per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton.
Arsenic (White)	£70-£75 per ton.
Bleaching Powder	Spot £11 7s. 6d. d/d. Contract £10 7s. 6d. d/d.
Bisulphite of Lime	£7 per ton, packages extra.
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£27 per ton
Potash Caustic	£35-£36 per ton
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d; Export £5 5s. per ton f.o.b.
Soda Caustic 76%	£20-£21 per ton.
Soda Crystals	£5 10s. per ton.
Sod. Acetate 97/98%	£26 per ton.
Sod. Bicarbonate	£10 10s. per ton.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	2⅞d.-3d. per lb.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, conc.	£16 per ton carr. paid.
Sod. Sulphite, Pea Cryst.	£17-£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£26-£28 per ton according to quantity.
Carbon Black	1s. 5½d. per lb. ex wharf. Still very scarce.
Chromium Oxide	1s. 5d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb. Firmer on advance in price of Rape Seed Oil.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

The market generally remains firm and there is a ready sale for all products. Particularly in the case of Brown Sugar of Lead there is a considerably increased demand. Wood Naphtha, both Miscible and Solvent, is scarce and also Charcoal of the higher grade retort quality.

Acetate of Lime—	
Brown	£10 15s. per ton d/d
Grey	£20 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 10s. per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d, ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 9d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 10s. per ton d/d.
Brown Sugar of Lead	£43 5s. per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 6d. per lb. Still fair inquiries but prices are slightly lower for delivery second half of year.
Crude 60's	3s. 6d.-3s. 9d. per gall. Market weaker.
Acid Cresylic—97/99	2s. 2d.-2s. 5d. per gall. Market quiet.
Pale 95%	2s.-2s. 4d. per gall. Not much demand.
Dark	1s. 10d.-2s. 0½d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	9½d.-10d. per gall. Not much demand.
Unstrained	9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8½d. per gall. Business slack, abundant supplies.
Pure	2s.-2s. 4d. per gall.
Toluole—90%	1s. 9d.-2s. per gall.
Pure	2s. 1d.-2s. 6d. per gall. Not much inquiry.
Xylol	3s.-4s. per gall. according to quality.
Creosote—	
Cresylic 20/24%	11½d.-1s. 0½d. per gall. Not much business.
Middle Oil	8½d.-9½d. per gall Market steady.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d.-9¼d. per gall.
Solvent 90/160	1s. 6d.-1s. 9d. per gall. Fewer inquiries.
Solvent 90/190	1s. 5d.-1s. 8d. per gall. Market steady.
Naphthalene Crude—	
Drained Creosote Salts	£7-£8 per ton. Market easier.
Whizzed or hot pressed	£11-£14 per ton.

Naphthalene—	
Crystals	£18 per ton.
Flaked	£16 per ton.
Pitch, medium soft	No business for this season. Prices for Autumn delivery 140s.-150s. per ton.
Pyridine—90/140	11s.-12s. per gall. More inquiries.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

The recent improvement in the business done in Aniline Dyes reported previously is still maintained. Business is coming through rather more freely. This is rather surprising in view of the fact that the Textile Trade is very quiet and we must anticipate that when the Textile Trade improves, the Aniline Dyes Trade will be still better. Prices are firm without advance, but there is no likelihood of any fall for some little time forward.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
p-Dichlorbenzol	£70 per ton.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	4s. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
p-Nitrobenzene	6½d.-7d. per lb. naked at works. Good demand.
Nitronaphthalene	1s. per lb. d/d.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.

Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80%	£47 10s.-£52 10s. per ton.
Acid, Acetyl Salicylic	In a somewhat weaker position as some holders are now accepting 3s. 3d. per lb.
Acid, Benzoic	2s. 6d. per lb. In shorter supply.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton. Prices reduced by £5 per ton.
Acid, Citric	1s. 9d. per lb., less 5%. Dearer; demand active; higher prices expected.
Acid, Gallic	3s. per lb.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb.
Acid, Salicylic	2s. 3d. per lb. would be accepted for quantity, showing a slightly easier tone.
Acid, Tannic	3s. 3d. per lb. Unchanged.
Acid, Tartaric	1s. 4d.-1s. 4½d. Demand continues to increase, and a period of hot weather should see a further rise in price. There is much more inquiry from the Continent and the U.S.A. and good business has been done for export.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d. per lb. is now wanted.
Amidopyrin	13s. 6d. per lb. without inquiry.
Ammon. Carbonate B.P.	£37 10s. per ton.
Atropine Sulphate	12s. per oz. Firmer but demand very poor.
Barbitone	18s. per lb.
Benzonaphthol	4s. 6d. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Bromides	Firmer all round, but prices have not yet been advanced as much as anticipated.
Calcium Lactate	2s. 9d. per lb. is the value for best English makes free from odour. Lower qualities are offered down to 2s. per lb., these being mainly of Continental manufacture.
Chloral Hydrate	4s. per lb. in shorter supply.
Chloroform	2s. 3d. per lb. for cwt. lots, ton lots being quoted down to 2s. per lb.
Creosote Carbonate	10s. per lb., with little enquiry.
Formaldehyde 40%	£90 per ton.
Guiacol Carbonate	8s. 6d. per lb. is the present value without any orders.
Hexamine	4s. 6d. per lb. The position is somewhat weaker for holders owing to arrivals from America which have nullified the high prices being quoted by Continental manufacturers.
Homotropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. Market good with considerable inquiry.

Magnesium Carbonate—	
Light Commercial	£38 per ton nett.
Magnesium Oxide—	
Light Commercial	£85 per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Menthol	35s. per lb. spot. Advanced.
Methyl Salicylate	2s. 8d. per lb. still quoted for carboys.
Methyl Sulphonal	14s. 6d. per lb.
Mercurials	Unchanged. Market quiet.
Paraformaldehyde	4s. Neglected.
Paraldehyde	1s. 5d.-1s. 7d. per lb. Forward prices show a much firmer tendency.
Phenacetin	Up to 7s. per lb. now quoted on a better market.
Phenazone	7s. 6d. per lb.
Phenolphthalein	5s. 6d. per lb.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	98s. per cwt., less 2½%. Firmer.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. Demand still continues good.
Potass. Metabisulphite	8d. per lb., 1-cwt. kegs included.
Potass. Permanganate	11d. per lb. Still firm.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Salol	3s. per lb. is the higher value now quoted.
Sod. Benzoate	2s. 6d. per lb., with better demand.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality. Demand improving and considerable business being done.
Sod. Hyposulphite—	
Photographic	£15-£17 per ton, according to quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d. per cwt. Fairly good demand.
Sod. Salicylate	In good supply. Values unaltered, being 2s. 9d. per lb. for Powder, 2s. 11d. per lb. for Crystal.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. per ton, according to quantity for home trade, 1-cwt. packages included.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 4d. per lb.
Thymol	Manufacturers are inclined to accept lower prices in order to meet Continental competition. Present value 17s.-18s. per lb.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES — London, May 18, 1923 — No. 20

EDITORIAL

SOME two months ago we referred in an editorial note to the various articles we had received on the definition of a synthetic organic chemical. We had the temerity to remark, " Sir William has given a proof that calcium carbide is a synthetic organic compound, so closely reasoned, so well supported by evidence and so lucidly explained that it seems incontestable." Things are not always what they seem. Mr. Chas. H. Herty, in his capacity as President of the Synthetic Organic Chemical Manufacturers Association of the United States, informs us that the Board of Governors of that Association has adopted a set of definitions prepared by a committee of seven representatives of the industry assisted by six scientists eminent in the field of organic chemistry. The definition of the term " synthetic organic chemical " is as follows :—" *Chemical.*—A material containing a preponderating proportion of an individual substance of definite elementary composition. *Organic chemical.*—A chemical containing carbon in combination with other elements. *Synthetic organic chemical.*—An organic chemical which has been produced by a controlled process involving change in chemical identity. . . . The term *Organic Chemical* is not applicable to the following chemicals : carbon monoxide and carbon dioxide ; carbon silicides, carbides, carbonates, bicarbonates, cyanides, cyanates, thiocyanates, ferrocyanides, ferricyanides, and cyanamides of metals or inorganic radicles. The term *Controlled Process* is to be interpreted as including not only the interaction of chemicals, but also the carrying out under pre-determined conditions of destructive distillation and biochemical conversion of raw materials by the agency of biologically pure cultures of organisms with exclusion of other organisms which would interfere with the progress of the desired reaction." The following notes are appended : " The isolation of a chemical individual from a mixture by the simple processes of mechanical separation, extraction with selective solvents, fractional distillation, or crystallisation, does not constitute a process involving change in chemical identity. In the case of a substance which may be classified either as a natural or a synthetic product, it shall be considered to be synthetic whenever it can be shown that it is produced in substantial commercial quantity by synthetic methods. Natural dyes are to be classified as synthetic chemicals only when the method of their isolation involves change in chemical identity."

* * *

The definition of chemical seems to be fairly wide and might include limestone, sandstone, sand, brick and glass. For brick there is some authority. Did not Lemery prepare oil of brick ? Are golf-balls materials containing a preponderating proportion of an individual substance of definite elementary composition ? If so, they are chemicals. We hope we shall receive in due course the reasoning which shows that the term organic chemical is not applicable to the list of chemicals mentioned by the Association. We are sure that it is not a mere dictum or opinion of the seven champions of industry assisted by the six eminent scientists. The Notes require a little further elucidation in order to free them from the last traces of ambiguity. Acetic acid in common parlance may be either natural or synthetic. Is it now produced in substantial commercial quantity by synthetic methods ? Nor are we quite clear whether the method of isolating natural indigo involves change in chemical identity. Perhaps Professors Thorpe and Morgan or Mr. W. A. Davis can enlighten us. We understand that Mr. Davis and Dr. Eyre have recently conducted a series of important experiments on evaporation and absorption in some underground cellar designed for the storage of a material containing a preponderating (but not the most exhilarating) proportion of an individual substance of definite elementary composition. But as their researches are very shortly to be published we will not seek to proticipate, as the lady said.

* * *

It is now well over one hundred years since Sir Humphry Davy, lecturing before the Royal Institution, described the safety lamp that bears his name, and the perennial fascination which the investigation of the mechanism of combustion has for chemists was once more revealed in the Friday Evening Discourse delivered by Prof. W. A. Bone last week in the theatre where Davy once spoke. Prof. Bone's subject was "Gaseous Explosions at High Pressures," and we wish to supplement the account published elsewhere in this issue by calling especial attention to certain very important aspects of his work. To put it briefly, Prof. Bone has found that, on exploding a mixture of carbon monoxide, oxygen and nitrogen in a steel bomb under a pressure of fifty atmospheres, the nitrogen absorbs energy from the rapidly vibrating molecules of carbon monoxide at the moment of explosion, becomes active or "activated," and is then capable of combining with oxygen to form oxides of nitrogen. Here then it would seem—disregarding the Häusser process, in which high pressures are not used—we have a potential method of nitrogen fixation for which a suitable raw material is available in abundance in blast-furnace gases. The lesson of the war is still too keenly felt for us to have forgotten the intimate connexion between nitrogen-fixation and national safety, and apparently all Prof. Bone has to do is to develop his process to large-scale application. Unfortunately, however, whereas the bomb now in use will withstand pressures of the order of 1000 atmospheres, further prosecution of the investigation requires a bomb that can resist very much higher pressures, pressures at which, so Prof. Bone anticipates, nitrogen can be made to burn as easily as carbon monoxide at atmospheric pressure. Until the new bomb is provided—and this seems too heavy a task for the funds of Prof. Bone's department—the work must be suspended. The discourse ended with the grave warning that if the work were not soon developed in this country, it would not be long before its significance was appreciated abroad. We can only hope that the imagination of those able to supply the deficiency in this country will be quickly stimulated and that we shall shortly have the pleasure of recording further advances in Prof. Bone's most important researches. Money can be found to build vast stadia, to finance Armenians, to construct huge men-of-war, and we refuse to believe that it will not be forthcoming to aid in solving the problem of nitrogen-fixation, for every ton of nitrogen fixed in this country makes war more remote and frees vast sums for works of peace.

THE LLANDARCY REFINERY OF THE ANGLO-PERSIAN OIL COMPANY

British chemical industries have gained an important addition through the establishment by the Anglo-Persian Oil Company at Llandarcy, South Wales, of their great refinery for the complete treatment of the crude oil brought from the Company's wells in South-Western Persia. This enterprise, which already has been in operation for nearly two years, producing petrol, kerosene, and fuel oils, will shortly be supplying a complete range of petroleum products, including all classes of lubricants, and various other oils for special purposes, as well as paraffin wax. When completely working this will be the only large-scale refinery operating in the British Isles for the treatment of imported crude petroleum and the manufacture from it of the whole series of products, of which the bulk heretofore used in this country has been imported from America, either fully refined or in partly manufactured form.

The establishment of this plant in South Wales has marked an important departure from the common practice of oil refiners, which had been to build their refineries at the nearest point to production of the crude oil that would permit of ready shipment to the consuming markets. It was thus something of an experiment to build the large plant at Llandarcy, though the arguments in its favour far outweighed the objections. The refinery has now been in operation sufficiently long to have proved the complete wisdom of the step taken by the company. Whilst the geological formation of Persia makes highly improbable any failure of oil from this source, the situation of this refinery in the British Isles safeguards supplies for the British Petroleum Company—the subsidiary organisation which distributes "B.P." motor spirit and other products refined at Llandarcy—as in case of any temporary interruption in supplies from the main field, crude oil to keep the refinery in operation could be drawn from other sources, and adequate storage at Llandarcy, both for crude oil and refined products, exists to cover any emergency.

To the chemical industry an obvious advantage of the establishment of this great refinery is the opportunity it affords to British chemists and chemical workers of doing in this country a large amount of refining work that hitherto has been done abroad. Since a very large part of the work in an oil refinery—even apart from that of the trained chemists—is of a character requiring skilled workers, the establishment of the Llandarcy plant has provided an opening for the more intelligent, and therefore valuable, class of worker in the district. At Llandarcy there is now a skilled refinery staff, the majority of whom have been trained by the nucleus of experienced chemists and engineers brought from the refineries of the Anglo-Persian and Burmah Oil Companies, in Persia and Burmah, respectively. As this and the other refineries which the company is now building through its associated or subsidiary enterprises in Scotland, Australia, and on the Continent further develop, the opportunities for skilled workers in this new home industry will expand.

An advantage derived from the employment of British labour is the production of more dependable and uniform products from the refinery established in Wales, than is usual with products brought from abroad. To this advantage the equable temperature at home, as compared with that in the tropical or subtropical countries where many refineries operate, adds still further to the uniformity of the various petroleum derivatives marketed in Great Britain under the "B.P." brand name. In planning the great refinery at Llandarcy the chemist and engineer worked in close co-operation, the experience gained by the Company's technical staff at the main refinery at Abadan on the Persian Gulf, forming a basis upon which to build, and to this was added the best results of refinery practice elsewhere throughout the world. Extensive research work under the direction of the Company's Chief Chemist and Chemical Adviser was a further preliminary, since the character of the crude oil to be treated is a most important factor in deciding the details of a refinery layout. In this particular instance, the paraffin content of Persian crude oil—permitting the extraction of wax and the production of all classes of lubricants—required the construction of important plant for these special processes.

The land on which the Llandarcy Refinery now stands was acquired as part of the comprehensive policy decided upon by the Company prior to the war. It was not, however, until February, 1919, that actual operations could be commenced. The area now occupied by the extensive plant, tank farm, and model village for housing the chief process workers—some 660 acres in all—was at that time waste land, the hilly portion a rabbit warren, and the lower levels bogland. When it is stated that the plant was put into operation in June, 1921, some idea can be gained of the enormous amount of work carried out during the period from 1919 to that date, the undulating slopes having been covered by an oil refinery equipped with the most modern plant capable of producing nearly 600 tons of petrol alone per day, as well as great quantities of lamp oil and other products. Incidentally, the capital expenditure involved in the enterprise was approximately £3,000,000.

Crude Bench with Pre-heating Apparatus

The crude oil (a thin, dark-coloured liquid of sp. gr. 0·837) is conveyed from Persia by the Company's tankers, of which the fleet, if placed end to end, would make a line nearly six miles in length, whilst their equivalent capacity is that of a 10 inch pipe-line extending for 22,000 miles. These tankers berth at the Queen's Dock, Swansea, where a special installation, embracing a subsidiary tank farm, pump house and pipelines, has been provided for rapid unloading, and for ready shipment of the refined products. From the dock area the crude oil is pumped through pipe-lines about 3½ miles long to the main tank farm, where there are 33 large tanks, all but eight of which are each of 10,000 tons capacity, giving a total storage capacity of upwards of 75,000,000 gallons. From the tank farm the crude oil is pumped to the service tanks on the hillside overlooking the refinery, ready for treatment.

Crude petroleum is essentially a complex mixture of hydrocarbons, but contains also, as impurities, varying percentages of oxygen, nitrogen, and sulphur compounds. These bodies are found in most petroleums and constitute the main portion of the impurities which the oil refiner endeavours to remove in order to obtain marketable products, or, in other words, products which will satisfy the market demands in the particular territory which he supplies. Crude petroleum is roughly classified as of :—(1) Paraffin base, (2) asphalt base, (3) mixed base, according to the predominating characteristics of the oil. It is to the last named class that Persian oil belongs.

The first operation of refining petroleum is that of distillation in order to separate the hydrocarbons present as completely as possible into the various grades of products required. At Llandarcy the continuous method of distillation is employed for the first treatment of the crude oil, the oil passing through the various units in a constant stream. Crude oil from the tanks on the hillside passes through pre-heaters into the crude-oil distillation units, the contents of the stills being brought to distillation temperature by means of oil fires. Preheating of the crude oil is effected by means of the residual oil from the distillation, which passes out at a temperature of about 230° C., imparting its heat to the incoming oil. This system of preheating at Llandarcy effects an economy of 50 per cent. in fuel costs. The vapours passing from the stills ascend dephlegmators or fractionating columns, and after passing through the distillate preheaters, are carried through the condenser tanks, which contain radiator-type fittings.

After condensation, the products pass into the tail house, where "look boxes" are arranged to enable the refiner to keep a close watch at all times upon the output of the stills.

The first distillation splits the crude oil into two parts :—Once-run distillate ; and fuel oil. This latter fraction is then ready to be pumped back to the docks at Swansea or to the railway siding on the works for the market ; or to be passed through the works for further treatment in order to produce lubricating oils, wax, and other by-products.

The once-run distillate flows from the crude oil stills by gravity to the benzine refinery, where it is washed by agitation in upright vessels with a solution of caustic soda, being partially decolorised in the process. The distillate so treated is then passed to the benzine rectification stills where further distillation takes place in order to produce the special fractions the market requires, which at the moment are petrol, and kerosene or paraffin oil. Heat for this latter distillation process is supplied solely by means of steam, the oil which passes into the receivers being first heated by means of closed coils and the temperature being further raised by the introduction of open steam.

For the final treatment, the petrol fraction is returned to the benzine refinery, where the petrol is washed with a slightly alkaline solution of sodium hypochlorite. The effect of this treatment is to remove by oxidation substantially all the reactive sulphur content. The finished petrol, now free of all impurities, is ready for market and furnishes motorists with the clear spirit known as "B.P."

The special process for eliminating impurities from the crude petrol by means of sodium hypochlorite referred to is a patented process evolved by the Company's Chief Chemist, and the refineries of the company have the monopoly of the patent outside America. At Llandarcy a special electrolytic plant is in operation, electricity to supply this being provided from the main power station at the refinery, and converted by means of rotary converters from a 3300 volt alternating current to a 200–220 volt direct current. With this plant it is possible to convert 10 tons of salt solution into sodium hypochlorite within two hours.

The kerosene fraction receives its final treatment by means of filtration through granulated bauxite, a reddish-brown aluminium ore. The bauxite, previously roasted, removes sulphur and colour, the oil coming from this process sweet in odour and perfectly colourless, being in fact the highest grade of lamp oil or kerosene. After a certain period of use the bauxite is re-roasted to burn out the impurities taken from the oil, after which it can be used again.

Both the kerosene and petrol, now ready for market, are transferred to their respective storage, large quantities being delivered to the dock area, whence they are shipped in special tank vessels to bulk-storage installations of the British Petroleum Co. at the main ports of the United Kingdom, or to subsidiary organisations on the Continent. Shipment of these products is also made by means of tank cars on rail to various points inland.

Part of the residue from the crude bench of stills, as previously stated, is sold as fuel oil, whilst the remainder goes to the pitch bench for further distillation. Here three cuts are made, namely, (1) heavy kerosene, (2) gas oil, (3) heavy oil and paraffin, the residue being a soft pitch. The third fraction becomes solid on cooling, due to the separation of crystalline wax, and its temperature is therefore kept above its setting point until it arrives at the paraffin sheds.

For the extraction of the wax an elaborate section of plant is provided, including a large refrigerating plant. The heavy oil and paraffin is pumped through long columns known as "Thompson's coolers," which contain coils in which cold brine is circulating. The oil is thus chilled, but is prevented from solidifying by a stirring gear, which keeps it constantly in motion. It then passes into the presses in the cooling rooms, these latter being kept at a temperature of 15° F. The oil is pumped through these filter presses, leaving behind a residue of scale or crude wax; whilst the liquid filtrate—technically known as "blue oil"—forms the base for lubricating oil and is passed on for further treatment through the sulphur dioxide plant.

The wax is sent through the hydraulic press house, melted, and then pumped to the sweating stoves, which contain cylindrical vessels having an annular space, which is filled with the scale. This scale is gradually heated by hot water, with the result that the oil sweats out and drains away from the wax. After this treatment the wax is run off and pumped to the refinery in a molten state, undergoing a final treatment of filtration though bauxite to remove the colour. Cooling sheds arranged with tiers of shallow pans facilitate the solidification of the wax, which is then ready for market.

Steam plays so important a part in modern refinery practice that the boiler house is literally the heart of the refinery plant. At Llandarcy the two most modern methods of steam raising are seen in operation side by side in the great boiler-house, where certain boilers are oil-fired and the remainder are heated by coal. For the latter the coal is received and conveyed into the furnaces automatically, the ashes being removed from under the boilers by means of a small runway, which conveys them to an ash elevator, and they are subsequently used for making paths and roads on the site.

Adjoining the boiler-house is the power-house, in which three steam turbines running at 3000 revolutions per minute are connected to A.C. generators of 2500 kw. at a pressure of 3300 volts. The switchboard (one of the finest in the country) is foolproof, each cubicle being under lock and key with interlocking and isolating links. Steam is generated at 180 pounds pressure, and after doing active work in the turbines, exhaust steam is drawn off at a reduced pressure of 40 lb. per square inch and is used for the distillation plant. The air-cooling plant under the power-house, commonly known as a wet-air filter, has a fan on the shaft of the generator, which draws air through the filter. A small pump is constantly circulating water in the form of a spray. The air passes through the spray, all dust is collected and the air passing through the windings of the generator is both cool and clean.

Lubricating-Oil Bench and Fireless Locomotive

During every stage of the refining process chemical tests of the oil are made as a matter of routine, a special laboratory for the purpose, with a staff under the direction of the Works Chemist, being part of the plant. These routine tests number nearly 1000 per day, and as a result of the care taken Llandarcy is turning out "B.P." motor spirit and other products which are achieving a reputation for uniform quality.

At Llandarcy an interesting detail of the laboratory equipment is a self-contained unit, in which experiments that promise success, when carried out on a miniature scale, with glass and test tube, are repeated with small working models. Another important development of the company is the establishment of a very complete laboratory at Sunbury in Middlesex, where a number of eminent research chemists are continually engaged in the study of the numerous problems connected with the commercial utilisation and the improvement in quality of the many products of petroleum.

The immense supply of water required for the steam plant and for cooling and other purposes, is provided by means of a reservoir containing some 15 million gallons and covering an area of 3½ acres. Centrifugal pumps force the water from this reservoir to an immense tank holding 250,000 gallons situated at the highest point of the refinery area. Some eight or ten million gallons of water are pumped round the circuit of the plant each day.

Constant precautions are taken at all times against fire—the oil refiner's bugbear—special refinery police and watchmen being constantly on guard, whilst efficient fire-fighting arrangements have been made to deal with any outbreak. An interesting detail of the refinery equipment designed to reduce fire risk is the "fireless locomotive," popularly known as a "Thermos Flask," several of which are used within the danger areas. These locomotives operate on high-pressure steam supplied from the central boiler plant, a twenty-minute charge keeping a locomotive going for four hours.

For housing the chief process workers, a model village has been laid out by the Company adjoining the refinery area. This village, known as "Llandarcy," to commemorate the name of the late Mr. Knox D'Arcy—the original concessionaire of the Persian oilfields—comprises over 100 houses picturesquely situated amid gardens in the style of a garden city. A second area, situated a mile or two from the refinery and known as "Cefn Park," has been set aside for the senior staff, for whom the Company has provided commodious houses. In addition there is a home farm of seventy acres, from which produce can be procured by the refinery staff.

With its immense concessions in Persia, its fleet of oil tankers, its refineries at Llandarcy, Abadan, and elsewhere, and its efficient distributing organisations, of which the British Petroleum Co. is the chief, the Anglo-Persian Oil Co. has a complete and effective organisation for carrying out its task as the only purely British oil enterprise in the field; and its activities to date justify the belief that this comparatively young company will become more and more a factor in the oil trade of the world, and recover for this country much of the business which in the past has been allowed to fall into outside hands.

THE EXPLOSIVES INDUSTRY

According to the report of H.M. Inspectors of Explosives for 1922 (Cmd. 1862. 6d.), for the first time in the history of the industry in Great Britain, no fatal accidents occurred during the year in factories registered under the Explosives Act, and only 11 persons were injured by the 51 accidents that did occur.

THE PREPARATION OF METOL*

By W. F. A. ERMEN

Although Metol (monomethylpara-amidophenol sulphate) was introduced as long ago as 1891 as a photographic developer by the firm of Hauff, very little has hitherto been published as to the method of manufacture. Paul in 1897 (*Z. angew. Chem.*, 1897, 171) stated that this body was most probably prepared by the action of heat on oxyphenyl glycin:

$$OHC_6H_4NH{\cdot}CH_2COOH = OHC_6H_4NH(CH_3) + CO_2,$$

but omits to state that this reaction only takes place when the glycin is first dissolved in an appropriate solvent.

Metol prepared in this way is quite innocuous to the skin. Direct methylation of para-amidophenol, by means of alkyl halides, calcium methyl sulphate or dimethyl sulphate, leads to an undesirable mixture, containing unaltered amidophenol, metol and very soluble higher methylated bodies, from which it is impracticable to isolate pure metol. Lapworth has recently overcome this difficulty by acting on benzalamidophenol (or cresol) with dimethyl sulphate. Benzalamidophenol can be prepared in good yield by stirring a solution of amidophenol or amidocresol hydrochloride with benzaldehyde in presence of sodium acetate. The benzalamidophenol is filtered off, washed, dried, and treated with a little more than an equivalent of dimethyl sulphate. The condensation product is then steam-distilled, the benzaldehyde being regenerated, and a solution of metol in sulphuric acid obtained. Some amidophenol is always regenerated, and some dimethylamidophenol is also formed; but the main product of the reaction is metol, containing about 7 per cent. of amidophenol sulphate. The metol prepared in this way also appears to be quite innocuous.

Merck's patent 260,234 describes a third method of producing metol, by acting at a high temperature on hydroquinone with an aqueous or alcoholic solution of methylamine. The metol produced by this method is found as the free base, partly dissolved in the reaction liquor, and partly as a dark brown oil. On adding sulphuric acid to the mixture the whole solidifies to a crystalline paste of metol. It is found that the alkaline reaction liquor is extremely irritating to the skin, rapidly raising blisters which break into sores that heal with difficulty. Very slight contact with the material may not even redden the skin, but causes severe pain, which is intensified on placing the hands in warm water, or holding them near a fire.

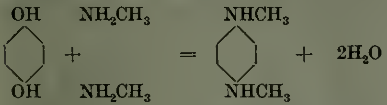
After filtering off the crystals of metol and carefully recrystallising them several times, this poisonous property appears to be removed.

---

* A communication from the Photographic Research Department of The British Dyestuffs Corporation, Ltd.

Even the base separated from the purified metol exhibits very little toxicity. The crude mother liquor, however, retains all the irritant qualities of the original reaction mixture. It appears to contain, besides unaltered methylamine and hydroquinone, mainly the very soluble sulphate of a base which is thrown out on addition of an excess of caustic soda as a dark oil. This oil, reconverted into the sulphate and recrystallised from alcohol, is obtained in the form of white, stable crystals, very soluble in water, and in dilute alcohol. In contact with the skin, intense irritation is caused in a very short time, so that one may affirm with some degree of certainty, that the poisonous action of metol is due to the presence of small traces of this substance.

From the fact that the base of this body is insoluble in caustic soda, one is led to the conclusion that it has been formed by the condensation of two molecules of methylamine with one of hydroquinone :—



sym. dimethylparaphenylenediamine.

That this is the constitution of the body is borne out by a determination of the proportion of sulphuric acid in the sulphate, and by titration with nitrous acid, with which it forms a double nitrosamine.

Further confirmation of this supposition was obtained by treating the benzylidine compound of paraphenylenediamine with dimethyl sulphate. As in the preparation of metol by the Lapworth process, a methylated phenylenediamine is obtained after steam distilling the reaction product, which appears to be identical, both chemically and in its toxic properties, with the body obtained by the interaction of hydroquinone and methylamine.

[We are glad to be able to publish the above account of Mr. Ermen's important investigation on the preparation of pure metol. Amongst photographic developers, metol is probably the one most widely employed, but hitherto it has suffered from the serious disadvantage of producing severe lesions on the skin of those using it. Mr. Ermen, however, has shown that this action is due to a substance usually present in small quantity in ordinary commercial metols and that by adopting a different method of manufacture, metol free from irritant action can be produced. Since metol was introduced in Germany some thirty years ago, the cause of its poisonous action has been the subject of much controversy among Continental chemists. It is therefore highly gratifying that the problem has been solved by a British chemist, and the work may be taken as evidence of the vitality of our fine-chemical industry, as exemplified by the British Dyestuffs Corporation.]

THE ALKALI CENTENARY

In the early manufacturing processes alluded to in the previous article on this topic the methods were comparatively simple. Liquids, or liquids and solids, were mixed together in a tub or vat, or solids were calcined in a furnace of simple construction ; the finished products were separated and purified and such of the by-products as could be conveniently utilised were treated by other processes, but as the number of chemical compounds rapidly increased and as electricity became an important factor in manufacturing operations, much more complicated methods were practised. The electric furnace, liquid gases, high pressure vessels and catalytic methods involving ingenious and complicated mechanical devices became necessary.

The processes of fermentation worked out by Pasteur in the middle of the last century have been largely developed and the early makers of alkalis undertook the manufacture of a great variety of compounds quite unconnected with the alkali industry, including, in many cases, the manufacture of explosives. Indeed, during the war, the manufacture of explosives by the alkali manufacturers formed a very notable addition to the fighting strength of this country. This is not the place to discuss these in detail, but the discovery of guncotton by Schöbein in 1845, of nitroglycerin by Sobrero in 1847, of dynamite by Nobel in 1867, the use of ammonium nitrate as an explosive, first worked out by Ohlsson and Norrbin in 1867, the manufacture of smokeless powder by W. F. Reid in 1882 and the discovery of cordite in 1889 and 1890, are important incidents in the progress of this industry. At first sight, it may seem singular that so simple a process as the ammonia-soda process should not have been successful on a commercial scale when it was first put into operation, but, like a good many other chemical processes, in practice the reaction is by no means so simple as is represented by the theoretical equation. It was found that a considerable excess of salt was required, and probably the process could only be economically conducted where salt was cheap and no heavy freight payable on it. The absorption of gases by the salt solution required a great deal of investigation before it could be successfully carried out on a large scale, and in addition there is always the loss of a small proportion of ammonia. Great care, complicated machinery, and the experience of many years are necessary to keep this loss of ammonia down to small limits, and although Solvay patented his new process on the lines of the original one of Dyar and Hemming in 1861, it took him some years before he was able to make it profitable. It was in 1873 that Dr. Ludwig Mond and Mr. Brunner commenced the manufacture of alkali by the Solvay process at Winnington, and, as is well known,

The Muspratt Works of the United Alkali Co. at Widnes they encountered very considerable difficulties during the first few years of their work. The technical difficulties were finally overcome by Dr. Mond, who worked day and night when some portion of the plant did not perform its allotted task. Dr. Mond combined great scientific knowledge with a determination rarely met with. He never despaired of success or spared any trouble or the expenditure of time or money to solve a problem which stood in his way, and his qualities, combined with the good business methods of his partner, finally overcame all the difficulties and enabled the works to enlarge until it became the greatest and most important in the country. The carbonic acid required for the ammonia soda process was obtained by roasting limestone, and the lime so produced was used to convert the ammonium chloride into ammonia and calcium chloride. The calcium chloride when treated with zinc oxide and carbonic acid, or with zinc carbonate, formed zinc chloride and calcium carbonate which could be used again. The zinc chloride was electrolized and so produced electrolytic zinc and chlorine, forming important materials for use in many industries. In 1887 the Castner process for the electrolysis of caustic soda was worked out, and in 1890 the large number of firms engaged in the Leblanc process for making soda combined to form the United Alkali Company, and doubtless effected many improvements in manufacture and many economies, and so enabled the United Alkali Company to become the powerful organisation which it is to-day. They have just celebrated the 100th anniversary of the Leblanc process in this country, and in a few weeks Messrs. Brunner, Mond and Co. celebrate the 50th anniversary of the Solvay process in this country.

Among the various developments associated with the alkali industry, the fixation of atmospheric nitrogen is one of the most interesting. The experiments of Kuhlmann on the oxidation of ammonia in 1839, the work of Regnault on making ammonia by sparking mixtures of nitrogen and hydrogen in 1840, and the attempts to make cyanogen compounds from atmospheric nitrogen by Bramwell in Newcastle at about that period were interesting but of no commercial importance. It was not until the Haber process was worked out in the years 1906, 1907 and 1908 that the fixation of nitrogen from the air, on a commercial basis, became possible. This process has led to interesting developments, both in this country and abroad, and we hope that Dr. Harker, whose letter appeared in last week's issue, will be persuaded some time to disclose the history which he has hitherto been not sufficiently indiscreet to set out in detail. Further developments, of course, will be forthcoming, and the latest is the work by Prof. W. A. Bone on exploding together mixtures of carbon monoxide, oxygen, nitrogen and other gases. By this method he seems to have converted nitrogen into an active variety, and the publication of his papers before the Royal Society and the Royal Institution is eagerly awaited.

THE STREAM-LINE FILTER

By PROF. J. W. HINCHLEY

A remarkable filter has been invented by Prof. Hele Shaw, F.R.S., whose work on stream-line motion of fluids is so well known and whose ingenious clutch, steering gear, hydraulic transmission, pipe joints and taps have made his name familiar all over the world. The filter consists of several thousand similar sheets of paper or fabric, impervious to the liquid to be treated, and pierced accurately with a large number of equidistant holes. The sheets are placed in a pack so that the holes coincide, and are secured between endplates. By means of channels formed in these endplates alternate rows of holes may be connected together as the inlet for the liquid to be filtered, whilst the other holes connect with other channels in a similar way, forming the exit for the filtrate. It will be realised that true filtration may take place between the sheets through the interspaces formed by the roughness of the paper or fabric.

By squeezing the pack the finest materials, bacteria, colloid particles, etc., may be retained by the filter, and on releasing the pressure it may be readily cleansed by driving a washing liquid in either direction. The formation of a hard cake is not allowed to take place, but the precipitate or residue is removed by allowing the contents of the inlet holes to discharge either intermittently or continuously through a suitable orifice. It will be realised that the filter possesses all the useful properties of a sand or porous pottery filter with the wonderful addition of a means of adjustment of porosity and of cleansing which puts it in a separate class.

Such a filter appears to be a great need of the time. Workers with the colloid mill know that a colloidal suspension with about 10 per cent. of solids is its usual product, and that such a product needs concentration before a real commercial benefit can usually be achieved. The stream-line filter will concentrate such solutions continuously to the point required by industry or to the point where drying by vacuum or other plant becomes a commercial proposition. Experimental work is being conducted which will demonstrate the usefulness of the filter in different industries and settle some of those questions which have arisen through the remarkable facility by which it removes discoloration and produces bright solutions.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

The Evening Meeting

of the London Section of the Society held last week somehow seemed to just miss the mark. It is difficult to say why. The subject was "The Action of Bacteria on Cellulosic Materials." It was introduced by Sir Frederic Nathan, who, realising the wide scope of the subject, contented himself by indicating the various heads under which the discussion might with advantage be carried on. He threw out a number of suggestions for the guidance of those who were to follow, but the subsequent speeches never seemed to follow the sequence suggested. Each was very interesting in itself; it was the correlation of them which bothered me. Mr. Lymm led off with carefully prepared details of work done by Mr. Laugwell and himself on the production of light motor fuel by the fermentation of cellulosic waste materials. Dr. Tyson dealt with the biochemical side of the subject. Dr. Page told us of the Rothamsted experiments for the production of artificial farmyard manure. So the discussion went on, with Dr. Ormandy in a pessimistic mood and Mr. Cross asking for definite information as to the price of alcohol and acetic acid. What everybody in chemical industry wants to know is how we are to obtain plentiful supplies of cheap alcohol. This we were not told.

In His Baeyer Memorial Lecture

Professor Perkin gave to those of us who never knew Baeyer a very convincing portrait of one whom we should all like to know, if not at first, then at secondhand. For an hour and a quarter Professor Perkin held us entranced while in an even placid voice he dealt with some of the outstanding characteristics of the great man. When he was describing his method of lecturing it so absolutely corresponded with his own that I felt that Professor Perkin had unconsciously modelled his style on that of Baeyer. From the age of nine, when Baeyer literally "brought chemistry into the home," till far on in life we can think of him only with a test-tube in his hand—a test-tube cleaned, as we were told, in his own way, first with dilute caustic soda, then with water, then with alcohol, then with distilled water. We can think of him peering at it, not anxiously to see if some pet theory is vindicated, but keenly to be sure that he missed nothing of the answer nature gave to the question he had put to her. He cared little for the theatre, for music or for what can only be described as "political chemistry"; but if he ever began to regret his keen concentration on his chosen subject, he would be the first to declare that it was this concentration which brought him his well-merited reputation. In proposing a vote of thanks to the lecturer Professor Armstrong spoke of Baeyer as the "Father of Condensation Chemistry," and it is to be hoped that this apt title will always be associated with the name of Baeyer.

The Chemical Engineering Group

have completed and duly celebrated another year's work. There have been times—a spirit of sweet reasonableness now prevails, brought about very largely, I believe, by the President and Treasurer of the Society on the one side, and the Chairman and Treasurer of the Group on the other. A deficit of £173 on the working of the past two years is wiped out by the Society, the Group presents its thanks, and everyone is happy. There might have been trouble between the Group and the new Institution of Chemical Engineers, but there has not been, and I do not think there is likely to be any. They are now sharing the same office and the same assistant secretary. Such exemplary conduct demands a reward, and this will be found in the steadily growing influence and sense of responsibility of the Group. The Group has recently been entrusted with the whole of the organisation of the Chemical Section of the World Power Conference which is to be held at the British Empire Exhibition at Wembley next year. *Vires acquirit eundo.*

The Meeting

of the Union Internationale at Cambridge is rapidly approaching. The delegates—and I hope every chemist of distinction in the country will be a delegate, for all such are invited—will be received by Sir Charles and Lady Walston on Sunday afternoon, June 17. On the following day there will be council and committee meetings and a discussion of Professor McBain's paper on "The Nature of Soap Solutions" and a reception by the Master of Sidney Sussex College and Mrs. Weekes. On Tuesday there will be other meetings and the annual dinner in Trinity College, and on Wednesday the presentation of honorary degrees at the Senate House and a reception by the Vice-Chancellor at the Fitzwilliam Museum. It is time the whole programme was published and the list of delegates, too.

The Royal Institution

provides scientific feasts in its Friday Evening Discourses and the discourse delivered by Professor Bone last week was no exception to the rule. But I was disappointed that he did not say more of the possibilities of his process for nitrogen-fixation. However, the conversion of laboratory into industrial work is nothing new to Professor Bone and his hint of possibilities may be only scientific caution.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL MEETING

CAMBRIDGE. JUNE 20 TO 23, 1923

Accommodation of Members in Colleges. Accommodation will be available for men in various colleges from the afternoon of Wednesday, June 20, to the afternoon of Saturday, June 23. Members who arrive on Wednesday will be charged an inclusive fee of £3, those arriving on Thursday an inclusive fee of £2. These fees include the use of a set of rooms (bedroom and sitting-room), attendance, gratuities to college servants and the following meals: *Wednesday, June* 20.—Tea (if required) and dinner. *Thursday, June* 21.—Breakfast, lunch and dinner. *Friday, June* 22.—Breakfast, lunch and dinner (if required). *Saturday, June* 23.—Breakfast, and lunch (if required). Members will usually take their breakfasts in their rooms. Luncheon and dinner will be served in the halls of colleges. On Thursday and Friday tea will be served at the Vice-Chancellor's reception, and at the Garden Party at Sidney Sussex College respectively. Members who arrive before five o'clock on Wednesday, and who will require tea, are requested to give notice to that effect on a form to be supplied. There will be no extra charge. Members unable to attend the Annual Dinner of the Society on Friday, and desirous of dining in college that evening, may do so without extra charge by giving notice to that effect on the form above referred to. Members who do not make the trip to Ely, and who require luncheon before leaving Cambridge on Saturday, may obtain it in college on that day without extra charge.

It is important to note that alcoholic drinks are not included in the charges specified above, and members requiring such drinks with their meals must sign a chit presented by the waiter at the time of ordering. Payment for such must be made by members at the office of the Society at the Arts School, Bene't Street, on Saturday, before departure. It is the wish of the college authorities that no money shall change hands at table, and it is hoped that members will kindly co-operate in order that this scheme of payment may be a success.

To the list of colleges offering accommodation given on page 469 of the last issue of *Chemistry and Industry*, Selwyn College is to be added. As previously stated, men requiring accommodation should communicate with Mr. J. E. G. Harris, the University Chemical Laboratory, Downing Street, Cambridge, who will supply any further information and forward a form to be filled up by the member.

The Smoking Concert on June 20 will be held in the dining room of the University Arms Hotel.

Group Photograph. A photograph of the members will be taken at the close of the Annual General Meeting on Thursday.

Guide to Cambridge. A copy of the illustrated Guide to Cambridge will be forwarded to each member who has purchased his ticket as soon as supplies are received from the publishers.

News. Further information will be published from week to week in this *Journal.*

J. P. Longstaff,
General Secretary

NEWS FROM THE SECTIONS

LONDON SECTION

The Annual Meeting was held at the Engineers' Club, London, on May 7, Mr. E. V. Evans presiding. The chairman announced that Dr. Bernard Dyer had accepted office as Chairman of the Section, and that Dr. Monier-Williams had agreed to continue as Hon. Treasurer and Secretary. Commenting on the change of place of meeting during the present session from Burlington House to the Engineers' Club, the chairman mentioned that there was not an absolutely unanimous agreement on the change, although he believed it had been generally appreciated. The Committee of the Section felt that more papers should be offered to the Section. The Section had 1400 members, and he had been surprised during his term of office at the difficulty which the Secretary often had in getting papers. The following were elected to fill vacancies on the Committee: Dr. J. P. Longstaff, Dr. E. H. Tripp, Dr. L. A. Jordan, and Mr. R. A. Punter.

Sir Frederic Nathan, K.B.E., in opening a discussion on "The Action of Bacteria on Cellulosic Material," said the discussion should be mainly directed to the industrial side. The action of bacteria on cellulosic materials, using both terms in their widest sense, might be considered for the purpose of the discussion as proceeding either naturally or artificially. The effects of natural action might be either harmful or beneficial, and as an example of beneficial action, first place must be given to coal. An example of harmful action was the deterioration, observed in 1906, of cotton waste in India; the cause was attributed to the climate. In 1917, supplies of cotton waste and cotton linters stored under adverse conditions were found to have undergone similar disintegration. It was found that under certain conditions of temperature and moisture, bacterial action was set up, and further, that cottons grown in different parts of the world were decomposed at different rates. Investigations were still proceeding, and it was hoped that means would be found for preventing or restricting this serious loss. Reference was next made to work at Rothamsted on the production of artificial farmyard manure, and to recent patents covering the production of acetic acid and alcohol from waste vegetable materials by direct bacterial fermentation. Again, experiments were being carried out at Nobel's explosives factory in Ayrshire upon the fermentation of cotton waste into practically nothing but methane and carbonic acid; the work was in its initial stage, but it offered possibilities for the production of formaldehyde and methyl alcohol. The conversion of waste vegetable materials into power gas had been examined at the Indian Institute of Science, Bangalore, and bacterial action on flax and other fibres was being studied. So far no micro-organisms had been found that would attack cellulose materials to produce alcohol directly and in such a way as to point to a successful commercial application. The method of subjecting grasses to acid hydrolysis gave good results and a process for treating sawdust and wood waste had reached application on a technical scale, both in France and Germany, the material being subjected to the action of strong hydrochloric acid, both liquid and gaseous, in plant of special material and construction. The yield of alcohol from the fermentation of the resulting carbohydrates was stated to be at least three times as great as that obtained by the older processes of Clason and others.

Mr. A. H. Lymm gave an account of researches by Mr. H. Langwell and himself upon the fermentation of cellulosic materials for the production of light motor fuel, the aim being to use waste materials that had no food or fodder value, such as maize waste and the various straws and grasses found abundantly in the tropics. Hitherto no process had been developed for transforming cellulose directly into useful organic products—the most important of which were alcohol and fatty acids—without the intervention of considerable quantities of relatively expensive chemicals. Most of the early work consisted of laboratory experiments, but the work of Mr. Langwell and himself, however, was on a large scale, utilising cultures up to 8000 litres in volume, and was partly embodied in British Patents 134,265 of 1918, and 161,294 of 1920, and four further patent applications on file. At first the investigations were concerned chiefly with the organisms to be employed, and as a result a bacillus was found which would rapidly attack almost every form of cellulose under either anærobic or ærobic conditions. It was found, however, that lignocelluloses (wood and jute) and cuto-cellulose (cork) were only attacked extremely slowly, if at all, unless the cellulose was first freed from combination. With these exceptions almost every form of carbohydrate (including starches and sugars) yielded to the attack of the bacillus. The work showed that a certain bacillus was the chief if not the only organism concerned in the general anærobic fermentation of cellulose according to the process worked out by Mr. Langwell and himself. It was found that two distinct types of colony were almost invariably obtained, but experiments showed that these were only forms of the same organism. A large variety of carbohydrates was tested, and they appeared to behave similarly, yielding products similar to those from the typical cellulose adopted as standards, filter paper in the laboratory tests and sulphite pulp in the large cultures. The rate of fermentation was also satisfactory, and varied from 24 hours for the sugars to about 5 days for the resistant celluloses. The products obtained could be varied, on the small scale, by varying the conditions of fermentation, without any change of organism. In practice, fermentation was carried on at 68° C., a temperature which automatically purified the culture and kept it free from contamination. It was only necessary to know the amount of fermentable carbohydrate in any substance to obtain a good idea of the possible yield of products from such a raw material by the process which had been described. The conclusion from these investigations was that a single organism was responsible for anærobic fermentation of cellulose, and it did not appear that this organism was similar in its behaviour on standard media to any species known to the authors. The organism might satisfactorily be cultivated at any temperatures from 37° to 65° C., the former being most suitable for pure culture work, whilst the latter appeared to be the optimum temperature.

Dr. Tyson, of the Royal Naval Cordite Factory, said that until quite recently the biochemistry of the cellulose fermentation was but little understood. Pringsheim showed that the bacterial breakdown of cellulose appeared to follow lines parallel to those already known from the chemical hydrolysis of cellulose and a further study of the bacterial decomposition of pure cellulose would materially assist in the elucidation of the cellulose molecule. Mr. Page (Rothamsted) referred to the experiments which have been carried out upon the production of artificial farmyard manure at Rothamsted. Dr. Harland (Cotton Research Association) said the work which was being carried out at the Shirley Institute upon the various types of mould which caused cotton fabrics to deteriorate indicated that cottons in which the nitrogenous material was reduced to a minimum, were very much less susceptible to attack by mould.

Mr. C. F. Cross expressed the view that the discussion had ranged over too large a field, and with the exception of Mr. Lymm, the speakers had failed to concentrate upon the most important aspect, viz., the industrial applications. In such a discussion it was most useful to keep to the practical industrial side. We wished to know whether alcohol could be made at £10 per ton or acetic acid at £15 a ton and he wished Mr. Lymm had said more of the industrial results achieved.

Dr. Hutchinson, speaking of work carried out in 1917 in an endeavour to dispose of the surplus straw produced as the result of the food production campaign, said it was found necessary to have an adequate supply of air, and also a supply of nitrogen preferably in an inorganic mineral form. Given these conditions, straw was rapidly broken down. Mr. H. E. Thornton (Head of the Bacteriological Department, Rothamsted) described experiments carried out on the application of unrotted straw to the land.

Dr. W. R. Ormandy agreed with Mr. Cross that the discussion had tended to the theoretical rather than the practical and spoke of a coming shortage in petrol supplies, to meet which alcohol would have to be produced. He did not agree that only so-called waste materials should be used for this purpose, as there were processes in Switzerland and Germany for the production of fermentable sugars from wood whereby it was possible to obtain 300 litres of 100 per cent. alcohol from one ton of dried wood substance. It was not a question of obtaining alcohol to compete with petrol at its present price, but at the price it might easily attain in the course of a year or two.

Mr. Langwell referred to the large scale upon which the experiments described by Mr. Lymm had been carried out and to the ease with which the products obtained could be changed over within a few hours from, say, acetic acid and methane at one end to lactic acid at the other end. On the technical side, the process was very far advanced. Dr. Lessing discussed the formation of coal, which was briefly touched upon by Sir Frederic Nathan, and said, with all respect to Dr. Ormandy, that our supplies of coal were far more important than the question of oil both in quantity and economic importance.

In replying to a hearty vote of thanks for opening the discussion, Sir Frederic Nathan agreed with what Mr. Cross and Dr. Ormandy had said as to the discussion not following the lines which he had sketched out. He had wanted more on the practical side and was disappointed that Mr. Langwell had not said something about the production of alcohol on a considerable commercial scale by his process. But he was not so pessimistic on the subject of oil supplies as Dr. Ormandy. He would like to know what proportion of alcohol would be obtained with that process from a given weight of straw, because that was the most likely source of alcohol in the future. Although the process to which Dr. Ormandy referred in which wood was treated with strong hydrochloric acid required large quantities of wood which were not available in this country, such a process might be possible in the United States, or Canada, as well as on the Continent. Hitherto, however, the production of alcohol from wood in the United States had not been successful commercially.

YORKSHIRE SECTION

The chairman, Dr. L. L. Lloyd, presided at the annual meeting held on May 7 in the Queen's Hotel, Leeds, and the following officers were elected for the ensuing session: Chairman, Dr. L. L. Lloyd; Vice-Chairman, John Evans; Hon. Local Secretary and Treasurer, B. A. Burrell. Messrs. F. W. Branson and W. J. Read were elected to fill the two vacancies on the committee. Subsequently, Mr. F. W. Richardson read a paper on "The Adulteration of Olive Oil."

Methods of testing olive oil for its suitability for oiling tops, as well as for detecting adulteration, are of great importance in the woollen industry, as an oil possessing drying properties may damage goods during storage. The question of adulteration should be approached with care as the various methods of extracting olive oil give a range of oils which have different constants, but yet are genuine olive oils. Years ago the author devised a test consisting in oxidising the oil in thin layers in a specially designed oven, hot air being drawn over the oil. Under this test, a good olive oil remains liquid, whereas rape oil becomes very viscous and linseed oil a hard varnish; the test is one of the best methods of detecting nut oil. If, after four hours' heating, an oil does not show any marked increase in viscosity, it will not oxidise markedly on oil tops in store. Some of the usual tests are unreliable, as genuine oils may be unsuitable, whereas an adulterated oil may be quite suitable; again, the tests may be of small assistance. It is not sufficient to rely on one fact, or even on a combination of data, in deciding whether an oil is adulterated or not, and when abnormalities are found the oil should be investigated further.

An olive oil was found to have an iodine value of 85·5, a potash number of 185, and a content of 2·8 per cent. unsaponifiable matter. Although the iodine value was rather higher than usual and the potash figure lower, these figures do not indicate adulteration. On further examination, however, suspicion was aroused when the result of a turbidity test did not agree with that of olive oil, and diazotised *p*-nitraniline gave an indication of rape oil. To ascertain if rape oil was present in quantities of 10 or 15 per cent., the Tortelli and Fortini test was used. The procedure adopted was the test as modified by Fryer and Weston, the "solid acids" being examined for iodine value and melting point. The mean values for olive oil were 7·8 and m.p. 58·5° and for rape oil 62 and 41·5°, but the suspected oil gave values of 20·8 and 53·5°. As there is no erucic acid in cottonseed, nut or sesamum oils, and as the figures agree with those given by a mixture of 15 per cent. rape oil with olive oil, it is almost certain that the oil was abnormal.

In the discussion, the Chairman said that all tests required further elucidation before oils could be definitely said to be adulterated

Colour reactions could not be depended on. Mr. W. McD. Mackey asked whether free oleic acid was not liable to oxidise, and also why Mr. Richardson suspected the presence of rape oil; the cloth tester definitely indicated the presence of oxidisable oils and he asked if it had been tried. Mr. B. A. Burrell stated he had found the Tortelli and Fortini test to be reliable for edible olive oil, but was it equally reliable for the ordinary commercial olive oils used in the woollen trade? Mr. Richardson, in reply, amplified some of the data which, to him, suggested adulteration. He had tried the cloth test and the temperature reached 320° F., a further abnormality, but he could not confirm that an oil containing free oleic acid was to be condemned; in fact he had found some eminently suitable. Naturally the oil had to be free from iron and copper catalysts. The Tortelli and Fortini test was very reliable for commercial oil and the figures given in the paper were for such oils.

MONTREAL SECTION

The Annual Meeting was held in the Queen's Hotel on April 16, and was preceded by dinner as usual. Dr. MacLean, the chairman, presided. The chairmen of the various committees reported on their activities during the session, the Reception Committee being particularly commended for their good work in bringing about greater friendliness among the members. The Nomination Committee made its recommendations for the Executive, and on the ballot being taken the following were elected:—*Chairman*, F. W. Horner; *Secretary-Treasurer*, C. F. Bardorf; *Committee*, Dr. A. R. M. MacLean (*ex officio*), Mr. J. B. Bell, Prof. LeCointe, Mr. N. Holland, Mr. C. C. Coll McFee, Mr. J. R. Macaulay, Mr. W. B. Woodland. Representatives of the guests from McGill and the University of Montreal expressed their appreciation of the hospitality extended to them by many Montreal business houses.

Mr. Munro then gave a summary of his prize-winning essay on the Manufacture of Newsprint Paper, an account of which will be given in a subsequent issue of *Chemistry and Industry*. The thoroughness with which Mr. Munro had studied his subject, during his vacations, was exemplified by the fact that he had joined a Trade Union in order to enable him to work with the men in overalls, thus acquiring the most intimate acquaintance, from the lumber camp to the sales office.

Professor LeCointe followed with a short discourse in lighter vein, on "Safety First," illustrated by humorous transparencies. The business of the evening being concluded, the members were entertained by musical selections by the McGill Quartet, Prof. Evans, F. J. Toole, H. Blackburn, C. W. Reynolds, D. Gillespie and J. Gillespie, the retiring chairman and the newly-elected chairman being accorded musical honours.

MEETINGS OF OTHER SOCIETIES

SOCIETY OF PUBLIC ANALYSTS

A meeting was held under the presidency of Mr. P. A. Ellis Richards on May 2 in the Chemical Society's Rooms. Five papers were read.

(1) "The Quantitative Determination of Hemp and Wood in Papers containing these two Fibres," by W. Dickson, F.I.C. The author considers that in the microscopical determination of hemp fibres in the presence of wood, examination alternately by ordinary and polarized light makes it possible readily to distinguish the microstructure of the different fibres. He has devised a method for quantitative work, utilising the counting method of Spence and Krauss. The paper is disintegrated by boiling with caustic soda and the pulp churned up with an egg switch. The fibre is then stained by the double Malachite Green and Congo Red method, and mounted in the usual way. The counting is done by Spence and Krauss's method, but no correction factor is required to convert proportions by diameter counting into proportions by dry weight of furnish.

(2) "The Estimation of Fat, Lactose and Moisture in Dried Milks," by H. Jephcott, M.Sc., F.I.C. As a result of examining over 25,000 samples of dried milk it is contended that: (1) Moisture is best determined by drying at 102-103° C. for 1 to 2 hours. (2) Fat can best be determined by a careful use of the Werner-Schmidt method; a modified Gerber method gives less accurate but concordant results for rough routine purposes. (3) The polarimetric determination of lactose in milk powders, whilst offering certain advantages, should not be used where great accuracy is desired. In such cases a gravimetric process, based upon the modified Fehling's method of Quisumbing and Thomas, is recommended.

(3) "The Determination of Lactose by the Polarimetric and Gravimetric Method," by A. L. Bacharach, B.A., A.I.C. Pure α-lactose monohydrate was prepared by careful recrystallisation and drying. It was shown to have the value for $[\alpha]_{D}^{20}$ of 52·42, agreeing with the most trustworthy recorded figure. The specific rotation of pure α-lactose monohydrate for the green line of the mercury-vapour arc was represented by the equation

$$\Big[\alpha\Big]^{t\;c=5}_{\lambda=546}=61{\cdot}94+(20-t)0{\cdot}085.$$

The reducing power of pure α-lactose monohydrate was also determined by the modification of the Fehling method due to Quisumbing and Thomas. The accuracy of this method claimed by these authors was confirmed, but the reducing power obtained was somewhat higher, 0·1000 g. of lactose hydrate giving 0·1565 g. of cupric oxide.

(4) "The Presence of Barium and Strontium in Natural Brines," by A. G. Francis, B.Sc., F.I.C. The results of the analysis of 7 samples

of brines from deep boreholes in Derbyshire, Staffordshire and Scotland are recorded, together with a brief account of the method of analysis adopted. The maximum quantities of barium and strontium chlorides found were 178·2 and 169·4 parts per 100,000, respectively. An explanation based upon the "permutit" reaction is put forward to account for the presence of the chlorides of barium and strontium in natural brines and it is shown that there is a gradation in the strengths of sodium chloride solutions necessary completely to remove calcium, strontium and barium from a "permutit" filter charged with these elements.

(5) "The Melting Point and Iodine Value of Refined Natural *d*-Camphor." by M. S. Salamon, B.Sc. The iodine value and melting point of specially purified *d*-camphor have been re-determined, and it is shown that the usually accepted iodine value is too high, and that the usually published melting point is too low. The iodine value of the specially refined *d*-camphor is found to be 0·1 and the melting point 179° C. It is concluded that the majority of previous determinations must have been made on *d*-camphor that was slightly impure. The iodine value of oil of camphor has also been re-determined, and examples are given of how this value, together with the melting point and iodine value of *d*-camphor, can be used to indicate the percentage of camphor present in a sample of refined *d*-camphor; this, for pharmaceutical purposes, should have a melting point not lower than 176° C. and an iodine value of not more than 0·7.

SOCIETY OF DYERS AND COLOURISTS

A meeting of the London Section was held on April 26, when a paper on "Fur Dyeing" was given by Mr. L. G. Lawrie.

Although the art of dyeing furs has been practised since the earliest of historical times, it is only recently that any notable progress by the use of fur bases has been made. In 1888 E. Erdman patented the use of paraphenylenediamine and similar compounds for the dyeing of hair, and it was soon realised that these substances could also be used for fur dyeing, and about 1895 the Berlin Aniline Co. introduced the first of its range of Ursol colours. These fur bases were principally diamines, amidophenols, diphenylamine derivatives, etc., which form coloured insoluble compounds in the presence of oxidising agents.

Before dyeing, the skins must be dressed and tanned. Various methods of tanning, such as alum and salt, or chrome tannages are used but the oldest and most important method consists in working seal oil into the skins, which are then allowed to "heat," 30° C. being the maximum safe temperature. After tanning the skins are wetted out in warm water, treated with an alkaline solution (*e.g.*, ammonia, soda lime, caustic soda) to ensure even dyeing, then mordanted with metallic salts, which produce deeper, more varied and faster shades, copper sulphate, sodium bichromate, ferrous sulphate and alum being the salts usually employed. The furs are then washed and dyed.

The furs are dyed by impregnating them with a solution of the fur base, together with hydrogen peroxide, and usually a little ammonia or a little acetic acid. There are two main methods of dyeing :—"Dip" dyeing, in which the skins are completely immersed in the dyebath ; and "brush" dyeing, in which the dye solution is brushed on the hair. In dip dyeing the necessary weight of fur base is dissolved in boiling water and the solution added to the dyebath, which is made slightly alkaline, acid or neutral, according to the base used and the shade desired. An amount of hydrogen peroxide (12 vol.) 12-15 times that of the fur base is then added to the bath and the mordanted furs entered cold or lukewarm. The furs are left in this solution for anything from 6-12 hours according to the depth of shade required. After dyeing they are thoroughly washed to remove any unaltered fur base. The "brush" method of dyeing is sometimes necessary owing to the fragility of some furs, but more often it is used in order to colour the tips of the hair only or to colour them differently after the whole skin has been dyed a ground shade. Several applications of the brush may be required, the fur being allowed to dry between each application. After dyeing, the furs are subjected to a finishing process to improve the leather and to bring out the full beauty of the furs.

ROYAL MICROSCOPICAL SOCIETY

At a meeting of the Industrial Applications Section held on April 25, Prof. Frederic J. Cheshire, C.B.E., in the chair, Mr. W. N. Edwards read a paper on "The Microscopic Structure of Coal."

With improved technique the microscopic study of coal has advanced considerably in recent years, illuminating not only questions of its origin and formation, but also more strictly economic problems. The necessity for minute investigation of the structure and properties of coal has not always been felt so strongly in a country like England, where high-grade coal is so abundant and so easily obtainable, as in places where much research has been necessary before coal resources could be utilised economically. Thus in Sweden it has proved possible to use a coal with 50 per cent. of ash in certain smelting processes. The study of microscopic structure has been of value in considering problems such as spontaneous combustion and inflammability of coal dust, and the collaboration of the chemist with the microscopist should go far to solve these and other problems and to ensure the best possible use of different coals industrially.

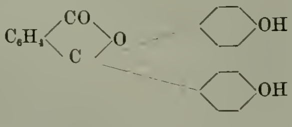
THE CHEMICAL SOCIETY

At the meeting held on May 3, the President, Prof. Wynne, recorded the death of Prof. E. H. Morley, an honorary Fellow of the Chemical Society, and said the Council might arrange for a Morley memorial lecture.

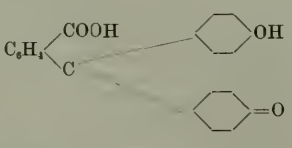
The first paper read was by Prof. H. B. Baker, on "Change of Properties of Substances on Drying. Part II." This work is a continuation of that published previously by Prof. Baker. It was shown that in taking the boiling point of the various liquids the high temperature was only observed when the thermometer bulb was immersed in the liquid itself. If the thermometer was suspended in the vapour above the liquid the rise above the usual normal boiling point was only 1°–2° C. at the most. The temperature of ebullition was taken to be that at which bubbles appeared freely in the liquid. In further experiments, several samples of the carefully dried liquids were sacrificed by boiling off the whole. With benzene the temperature of the vapour rose from 81° at the beginning to 88° C. at the end of the distillation. Evidence of change of melting point was also given. Dry benzene had m.p. 6·0° instead of 5·4°. Sulphur trioxide dried one month over phosphorus pentoxide had m.p. 50°, but that dried for several years had m.p. 61°. Two instances of abnormal vapour density were given :—

Ether, dry	B.p. 83°	V.D. 81·7
,, normal	B.p. 35°	V.D. 37
Methyl alcohol, dry ..	B.p. 120°	V.D. 45
,, ,, normal ..	B.p. 65°	V.D. 16

The second paper, entitled "The Sodium Salts of Phenolphthalein," by H. Bassett and P. Halton, was read by the latter author. Both colourless and coloured alkyl derivatives of phenolphthalein are known, a benzenoid structure being assigned to the former and a quinoid to the latter. The colour changes with phenolphthalein itself in aqueous solution are supposed to be due to a tautomeric equilibrium between the colourless



and the coloured



the former representing free phenolphthalein and the latter the red alkali salts. As little is known about the salts, especially when in the solid state, an examination was made of the three-component system phenolphthalein, sodium hydroxide and water. At 25° mono-, di- and tri-sodium salts were obtained as crystals each in the form of several different hydrates, and the di-sodium salt was also obtained in an anhydrous state. All these salts are colourless. Therefore in the deep red solutions from which these crystals separate there is probably a complex equilibrium between colourless mono-, di- and tri-salts and coloured mono- and di-salts.

"The Action of Thiosulphates on Cupric Salts" was the title of a paper by H. Bassett and R. G. Durrant. Prof. Bassett stated that the reaction between sodium thiosulphate and acid solutions of cupric salts leading ultimately to the precipitation of cuprous sulphide and sulphur consists in the first place in the reduction of the cupric to the cuprous with simultaneous oxidation of thiosulphate to tetrathionate. This occurs at once at ordinary temperature on mixing neutral solutions, the reduction being possible because excess of thiosulphate at once converts the cuprous copper into comparatively stable complex sodium cuprous thiosulphates. By change of concentrations several of these compounds can be isolated in the solid state, *e.g.*, $2Na_2S_2O_3$, $3Cu_2S_2O_3$, $6H_2O$; $Na_2S_2O_3$, $Cu_2S_2O_3$, $3H_2O$; and $Na_2S_2O_3$, $Cu_2S_2O_3$, H_2O. From a solution of cupric nitrate, $2Na_2S_2O_3,3Cu_2S_2O_3,6H_2O$ is obtained in a pure state, but when prepared from a sulphate solution it always contains some of the corresponding double sulphate $2Na_2SO_4,3Cu_2SO_4,6H_2O$ in isomorphous admixture. From the chloride, $Na_2S_2O_3,Cu_2S_2O_3.H_2O$ is obtained with some of the isomorphous Na_2Cl_2,Cu_2Cl_2,H_2O. All these double thiosulphates are hydrolysed on boiling, the action being rapid with acids. Cuprous sulphide and sulphur are precipitated, and when this occurs in contact with tetrathionate a portion of the latter is converted into pentathionate by the nascent sulphur. The filtrate consequently gives a precipitate of sulphur when made alkaline ; a characteristic reaction of pentathionates.

"The Conditions of Reaction of Hydrogen with Sulphur. Part II. The Catalytic Effect of Oxygen. Part III. On the Mechanism of the Reaction of Hydrogen with Sulphur and its Catalysis by Oxygen." In this paper, by R. G. W. Norrish and E. K. Rideal, Mr. Norrish drew a distinction between volume reaction, surface reaction and gaseous reaction, and the effect of oxygen in catalysing the reaction between sulphur and hydrogen and *vice versa.*

The last paper, read by Prof. T. M. Lowry, was entitled "Studies of Electrovalency. Part II. Co-ordinated Hydrogen." It started with the evidence of the ice crystal that hydrogen attracts two oxygen atoms and could thus itself act as a co-ordinator. He then applied his theory to special cases, which before had been difficult of explanation.

ROYAL SOCIETY OF ARTS

On May 9 Professor W. A. Bone read a paper entitled "Surface Combustion with special reference to recent Developments in Radiophragm Heating." The lecturer gave a brief summary of his experimental results and then showed that: (1) According to their chemical nature and physical texture all hot surfaces, at temperatures below ignition point, have the power of accelerating gaseous combustion in different degrees; (2) at high temperatures this difference in power of acceleration practically disappears; (3) during combustion the chemical action occurs mainly in, and is usually confined to, the boundary layers between the gaseous and solid phases; (4) the accelerating influence rapidly increases with rise in temperature; and (5) all surface combustion depends upon the absorption of the combustible gas, and probably the oxygen by the surface, thereby becoming activated through association with the surface. The work done in collaboration with the late Mr D. C. McCourt, which resulted in the installation at Skinningrove Iron Works of two boilers fired on this principle with coke-oven gas, was next reviewed. Unfortunately the "Radiophragm," developed during this period, proved difficult to manufacture, and possessed the disadvantage of pre-ignition if working at a temperature above 900° C. Recently the work has been resumed in conjunction with Mr. F. J. Cox, and both flat and circular radiophragms have been made, which are capable of working at much higher temperatures without danger of pre-ignition. At the conclusion of the lecture a demonstration was given on various types of these new radiophragms. which have found a wide variety of industrial applications.

ROYAL INSTITUTION

The Friday Evening Discourse on May 11 was delivered by Prof. W. A. Bone, on the subject of "Gaseous Combustion at High Pressures." In his discourse, Professor Bone described the steel bomb, the Petavel gauge for measuring the pressures generated in the bomb and the method by which these pressures taken over intervals of time of 1-100 of a second were recorded, and then proceeded to give an account of the work carried out with the assistance of the late Mr. W. A. Hayward. In this work it was found that when a mixture of carbon monoxide, oxygen, and nitrogen, capable of liberating the same total amount of energy as a hydrogen-air mixture was exploded, the time taken to reach the maximum pressure was much longer in the former than in the latter case, also that the cooling in the case of the hydrogen-air mixture took place immediately, whilst in the former case the cooling was delayed for quite an appreciable interval, thus showing that heat energy was being liberated long after the maximum pressure had been reached. To elucidate these differences and to determine the part played by nitrogen, mixtures consisting of carbon monoxide and oxygen, to which were added either nitrogen, oxygen, argon, or hydrogen in definite and varied amounts, were exploded in the bomb. It was found that the times taken to reach the maximum pressures in the case of the oxygen, hydrogen, and small amounts of argon diluents, did not differ greatly from those obtained with hydrogen-air mixtures, whereas the nitrogen mixtures were much slower, the length of time required to reach the maximum pressure being appreciably affected by the amount of nitrogen present. It was also found that with nitrogen mixtures the ratio of the final to the initial pressure was much less than with either the oxygen, argon or hydrogen mixtures and that the washings of the bomb after an explosion of a nitrogen mixture showed distinctly the presence of nitric acid.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on May 10, Sir William Pearce presiding in the absence of the chairman, Sir Max Muspratt.

An interim report was received in connexion with the quantity of fuel consumed by members of the Association during 1922, and when the final report is available the information will be passed to the Mines Department.

In connexion with the Sixth International Mining Exhibition the Association has arranged for two lectures to be given on Thursday, June 12, 1923, one by Mr. E. I. Lewis, of Messrs. Albright and Wilson, Ltd., on the subject of "Fine Chemicals," and the other by Mr. Edmund White dealing with "Rare Earths." Sir William Pearce will occupy the chair.

The arrangements for the Chemical Section of the British Empire Exhibition are moving very satisfactorily. With the exception of about 3000 sq. ft. the whole of the space allocated to the chemical industry has been taken, and it is anticipated that by the end of the month all the space will be booked. Nearly £2000 has already been subscribed towards the expenses of the scientific exhibit.

Dr. Clayton, M.P., reported that the Salmon and Freshwater Fisheries Bill has passed the Committee stage of the House of Commons in such a form as would not be inimical to the interests of chemical manufacturers.

The General Manager presented a report dealing with the proposed compulsory marking clause in the Merchandise Marks Bill, and said that certain suggestions have been laid before the Board of Trade as to the best methods to adopt in dealing with this vexed question.

A report from the Transport Manager disclosed that the new conditions of carriage of merchandise by goods train at company's risk had been settled by the Railway Rates Tribunal, and many valuable concessions obtained.

NITRATES FROM THE AIR

In the first of the series of Cantor lectures delivered before the Royal Society of Arts on "Nitrates from the Air," Mr. A. Kilburn Scott mentioned the reasons which led the Ministry of Munitions to instal a small cyanamide factory at Dagenham Dock and ultimately to erect a large factory for the manufacture of ammonia by the Haber process at Billingham-on-Tees. Dealing with the fixation of nitrogen by the arc process he pointed out that this method entailed the least possible amount of labour and the minimum cost for raw materials. In the manufacture of nitrates by the arc process, the furnaces may utilise single- or three-phase alternating current. Belonging to the single-phase type in which the furnaces have to be used in sets of three are the Bradley and Lovejoy, and the Island furnaces, in which the formation of the arc is accomplished by mechanically moving parts, the Birkeland-Eyde and Moscicki furnaces using a magnetic field to direct the arcs, the Schönherr and Wiegolofsky furnaces having a fixed arc, and the Pauling and Heckenbleckner varieties in which air currents are employed to direct the arcs. The Kilburn Scott furnace having air blown arc flames and pilot arcs and the Nitrum furnace in which air currents are employed to rotate horizontally a disc-like arc, are furnaces in which three-phase alternating current is used in each reaction chamber.

It was stated that the usual production from the single-phase type of furnace, employed in Norway, amounted to 62 g. of nitric acid per kw.-hr., whilst tests on the three-phase type of furnace had given between 90 and 100 g. of nitric acid per kw.-hr. The commercial importance of the arc process was illustrated by figures of the output of the Norsk Hydro-Elektrisk Kvaelstofaktieselskab, which, using furnaces of the original Birkeland-Eyde type and a more recent type, supplied to the specification of the Badische Anilin und Sodafabrik, manufactured during 1919, 67,419 tons of nitrate of lime and exported 50,000 tons of nitric acid, sodium nitrite, sodium nitrate and ammonium nitrate. The lecturer described the Pierrefitte plant, in which there are four Birkeland-Eyde furnaces, each 10 ft. in diameter, fitted with water-cooled electrodes and consuming 4000 kw., and it was stated that with this plant nitric acid could be manufactured at a cost of £6 per ton; power costing 20s. per kw. year. As illustrating the three-phase system the furnaces used by the Nitrum Co. of Zurich were taken. These furnaces, varying in size from 700 to 8500 kw. consist of three adjustable, water-cooled electrodes operating in a firebrick-lined cylinder into which the gases are introduced tangentially, thus keeping the walls of the cylinder cool, and at the same time producing a horizontal disc-like arc. The oxidised gases leave the chamber at the centre of the arc at high velocity through a water-cooled pipe, which rapidly cools the gas and gives a concentration of from 2·5 to 3 per cent. of oxides of nitrogen. When oxygen is used the yield of nitric acid is from 75 to 80 g. per kw.-hr. The lecturer accounted for the inability of the 300 kw. Scott three-phase furnace installed at Messrs. Kynoch's works, to realise the figures obtained from the experimental plant, by stating that after the issue of the report of the Nitrogen Products Committee, it was found that the electric meter used was reading 100 per cent. high.

The first part of the second lecture dealt with the capital cost of the alkali and acid absorption towers, which account for nearly half the total cost of the plant. It was pointed out that the problem of reducing this great capital outlay could be solved by increasing the percentage of nitric acid, as in the Nitrum furnace, for an increase of from 1½ to 2½ per cent. concentration would result in a reduction of those towers to one quarter of their original size. Another method would be to pass the gases through the towers under pressure as adopted in the latest type of Häusser plant, in which metal towers are used into which the gas passes at a pressure of about 45 lb. per sq. in. In this case the towers can be reduced to one-fiftieth of the size required when working under atmospheric pressure. Mr. Scott suggested that future improvements in the arc process would be obtained by passing equal quantities of nitrogen and oxygen into the furnace, and, as recent researches of C. P. Steinmetz seemed to indicate, by maintaining the pressure inside the furnace between 50 and 100 lb. per sq. in. The second part of this lecture was devoted to recent developments in the Häusser plant and a detailed description of the Muscle Shoals plant in America was also given. The improvements in the Häusser plant consist in increasing the capacities of the bombs used, forming the absorption towers of acid-resisting steel alloys, and passing the gases through those towers under pressure. With improved plants of this type it is possible to obtain a yield of 200 g. of nitric acid per cb. metre. The Muscle Shoals plant was intended to produce 40,000 tons of fixed nitrogen per annum. Twelve rectangular furnaces, formed of steel and lined with fire-brick, each 12 ft. by 22 ft. by 16 ft., were installed, each furnace being capable of producing 50 tons of carbide per 24 hours. After cooling the carbide is crushed in an atmosphere of nitrogen until 85 per cent. will pass through a 200-mesh sieve; 1536 electric ovens, each containing a charge of 1600 lb. of pulverised carbide, are used to convert the carbide into cyanamide, the carbide being heated in an atmosphere of nitrogen to 2000° F. for 40 hours. After cooling, the cyanamide is again crushed and ground until 95 per cent. will pass through a 200-mesh sieve and is then treated with water to remove any free carbide. This finely ground cyanamide is then treated with superheated steam at 150 lb. pressure, when pure ammonia gas is evolved, the sludge, containing carbonate of lime, caustic soda and free carbon, passing to a set of Oliver filters, where the weak caustic soda is recovered. To produce oxides of nitrogen the ammonia mixed with air in the proportion of 1 to 10 is passed over a catalyser, consisting of platinum gauze heated to 750° C. The gas enters at the top of the catalysers, 696 in number, and the oxides leave at the bottom and after passing under boilers enter the towers and coolers. Special precautions are taken to obtain pure air for the liquid-air plant and every effort has been made to recover the heat from the gases leaving the catalytic chambers. Although it has never been used commercially this plant has already cost 107 million dollars, and if Mr. Ford acquires it he will spend a further 100 million dollars to complete it. Of this sum 15 million dollars will be spent on a plant for the manufacture of phosphoric acid from Florida phosphate rock.

At the beginning of the third lecture Mr. Scott referred to the Humphrey pump and discussed its application to the Häusser process, and then described the Haber process in which ammonia is formed by passing hydrogen and nitrogen over a pure iron catalyst. The nitrogen for this process is obtained from Linde liquid-air plants and the hydrogen may be obtained, either electrolytically or from producer gas. If the first method is employed 75 per cent. of the power required would be utilised to produce hydrogen. When hydrogen is obtained from producer gas it is necessary to remove by freezing the carbon dioxide, which poisons the catalyst. The gases before entering the catalyser are compressed to 200 atmospheres and the catalyst is maintained at a temperature of 550° C. The Claude process also passes hydrogen and nitrogen over a catalyst, but in this case the gases are previously compressed to 900 atmospheres. Under this pressure it is found that the heat of reaction is sufficient to raise the temperature of the incoming gases to 500° C. Claude's latest type of catalyser consists of two concentric tubes, the inner containing the catalyst. Cold gas enters at the bottom of the annulus formed by these tubes and passing upwards, is heated by the heat generated within the catalyst. The walls are so designed that the heat absorbed by the incoming gas will be just sufficient to raise its temperature to 500° C. as it enters the catalyser material.

In the discussion which followed Dr. Harker pointed out that the enriched air arc-process, which had been adopted in three plants in Switzerland and Germany, had ended in disaster, the plants being wrecked by explosions. He also touched on the developments which were going on at Billingham-on-Tees.

PERSONALIA

Sir J. J. Thomson has been elected honorary professor of natural philosophy and Sir E. Rutherford professor of natural philosophy in the Royal Institution.

The Department of Scientific and Industrial Research has constituted a special committee of the Building Research Board to report on the best methods by which the decay of building stones may be prevented or arrested. The chairman will be Sir Aston Webb, and the members of the committee include Prof. C. H. Desch, F.R.S., Sir Herbert Jackson, K.B.E., F.R.S., Dr. A. Scott, F.R.S., and Mr. H. M. Weller, M.I.C.E.

Dr. G. K. Burgess has been appointed director of the United States Bureau of Standards in place of Dr. Stratton, who resigned to become president of the Massachusetts Institute of Technology.

E. P. Mathewson has been elected President and T. T. Brewster and F. M. Smith have been elected Vice-presidents of the American Institute of Mining and Metallurgical Engineers for 1923.

Prof. Brodhun has been appointed director of the Physikalisch-Technische Reichsanstalt, Berlin.

* * *

Landrat M. Rotger, formerly chairman of the firm of Krupp and president of the Office for German Industry during the War, has died at the age of sixty-three. The deaths are also announced of A. Wellenkamp, well known in the potash industry; of Prof. G. Barkhauens, Rector of the Technical *Hochschule*, Hanover; and of Dr. E. Reiss, who had worked on blood serum, on uræmia and on the electrical degeneration of the muscles.

FORTHCOMING EVENTS

May 24. Society of Chemical Industry, *Birmingham and Midland Section.* A visit has been arranged to the works of Messrs. Cadbury Bros., at Bournville. The number is limited, and members should notify the Hon. Secretary at an early date.

May 24. The Royal Institution of Great Britain, 21, Albemarle Street, W., at 9 p.m. "Engineering Problems solved by Photo-elastic Methods," by E. G. Coker, D.Sc., F.R.S. (Lecture 2.)

May 28. The Faraday Society, at the Institution of Electrical Engineers, Victoria Embankment, W.C. 2, at 3 p.m. Discussion on "The Physical Chemistry of the Photographic Process."

May 31. The Royal Institution of Great Britain, at 3 p.m. "The Nature of Enzyme Action," by Sir W. M. Bayliss, LL.D., D.Sc. Also on June 7.

CORRESPONDENCE

TURPENTINE AND WHITE LEAD POISONING

Sir,—In confirmation of the conclusion arrived at by the Norman Committee respecting the alleged poisonous nature of turpentine vapour, viz., that it is not the cause of the symptoms attributed to acute or chronic lead poisoning, and that there is no evidence that the inhalation of turpentine fumes induces chronic "Bright's disease," I can furnish very pertinent evidence.

In one part of the Sanitas Company's factory over a period of many years a considerable number of men, boys, women and girls was engaged in regular and continuous work, the atmosphere of the building being all the time fully impregnated with turpentine vapour arising from operations with thousands of gallons of the liquid in a heated condition, and during the whole of that time there was never a complaint of any kind; neither acute abdominal pain, headache or any other disorder; indeed, it would be difficult to find a healthier lot of people.

I brought this information to the knowledge of Sir Kenneth Goadby in June, 1921.

As to the assumption of poisonous plumbiferous vapours emanating from white lead paint, I quite agree with Professor H. E. Armstrong that it is without any foundation, and that white-lead poisoning is to be attributed to the dust produced in rubbing down dry.—I am Sir, etc.,

C. T. Kingzett

"Newlands," Weybridge
April 20, 1923

THE TITLE "CHEMIST"

Sir,—The Institute of Chemistry, through its President, Mr. Chapman, raises the question of "title" to the designation of Chemist in an appeal to the public through the Press, or rather, in an appeal to the pharmacist usurpers, with the public cited as witness or more correctly *qua judex*. We English chemists have long accepted our anomalous position, looking to the Institute to bring the pharmacist to the status corresponding with that of the French *Pharmacien* and the German *Apotheker*. And we still look! Chemists would agree that it would waste our time and energies to engage in a controversy which would merely emphasise the fundamental unrealities of the position. In regard to the realities, which we all recognise, I suggest for consideration a terminology of classification subject to revision as regards etymology.

The discussion of this, or alternatives to be suggested, may contribute to a clear understanding on some matters of moment. Thus we appear as a body to have generally accepted the terms "Pure and Applied Chemistry" as an antithesis of Apostolic sanction. The use of these terms has had a polarising influence leading to fixed ideas. I suggest we may with advantage revise these terms, with others, to express what we really mean. Thus, the science of chemistry is a holothetic discipline. Applied chemistry may be fitly described as heterothetic. With the professional practice of the science as such, there enter a number of values, both technical and industrial, which require to be treated by exact method and are in fact factors of problems truly scientific. That this is a more correct terminology would appear from one illustration. Physiology is really applied chemistry, and on the old terminology the physiologist is denied any claim to follow the cult of the "pure" science, so called. This excommunication is not intended. These terms, current for so long, are inexact and lead to confusion of idea. Should we adopt such terms as suggested, we should have to consider whether the equivalent terms holo-chemist and hetero-chemist are acceptable, and whether they are etymologically sound. Outside the two groups of chemists connoted by the above division there is the group of "chemists" who associate with the practice of a section of the science, the trading, as wholesale or retail vendor, in chemical products alone or in association with miscellaneous goods. This group would include the shop-keeping pharmacist, the drysalter or wholesale druggist, laboratory furnishers, dealers in nostrum articles and perhaps the *dilettante* patrons of our science. If we had to find collateral terms for such as these, it is suggested that the words "amphithetic" and "amphichemist" should be considered.

Incidentally to a discussion amongst ourselves on these lines, we might succeed in enlightening the public and, indeed, educating it to the point of seeing the humorous side of those extraordinary products of our insular civilisation, the "chemist's" shop and the blue-bottle "chemist." Where the Pundits have failed to establish the "Pucka" chemist, the appeal to Puck may avail something.—I am, Sir, etc.,

THE NITROGEN INDUSTRY

Sir,—Prof. Partington's letter of April 27 on the subject of Dr. Harker's review of our book on "The Nitrogen Industry," raises again a question the importance of which cannot be over emphasised.

Of recent years it has become a chemical platitude that the prosperity of a nation is measured by its consumption of sulphuric acid. I venture to express the opinion that the time is not far distant when this criterion will be the national production of combined nitrogen, in whatever form, and from whatever source. Prof. Partington refers playfully to the jousting between the "technical experts" and the "pure chemists." Such bickerings are inevitable among the professors of an inexact science and do no real harm to either side—fraternal strife judiciously controlled makes for a healthy family. But the choler expended thus wise is but as the bun flung from brother to brother across the family tea-table as compared with the greater *political* campaign which will be necessary before our national house is put in order. The chemists (both "pure" and "technical") are alive to the importance of the nitrogen problem, and progress has undoubtedly been made, even since the writing of our book.

The bureaucrats and the "administrative experts" have now to be convinced. One does not despair, but is given to wondering whether a threat of national extinction will again be necessary in order to supply the necessary stimulus in Olympic circles.—I am, Sir, etc.,

Experimental Station, Porton, Wilts

THE ORIGIN OF TWADDELL'S HYDROMETER

Sir,—In the event of any of your readers having knowledge of the inventor and origin of Twaddell's Hydrometer it would be of interest to put it on record. I believe that he was a workman at a Tyneside chemical works, but this piece of biography, or even the correct spelling of his name, does not seem to be known with certainty. Only those familiar with his hydrometer can really appreciate the many practical advantages of that instrument in chemical works.—I am, Sir, etc.,

NATURAL TANNINS

Sir,—In the "Reports of the Progress of Applied Chemistry" for 1922, Mr. D. Woodroffe (p. 355) makes the statement: "The work of E. Fischer is being consolidated and supported by fresh investigations on natural tannins." In support of this statement Mr. Woodroffe gives the following two references: *Trans. Chem. Soc.*, 1922, **121**, 23; *Helv. Chim. Acta*, 1922, 5, 108. The first reference is to my paper on "Paullinia Tannin." This paper does not confirm Fischer's ester formula, but it shows conclusively that Paullinia tannin is a *normal glucoside* and not an acyl derivative of glucose. The second reference is to a paper by Karrer and Solomon, which deals with the syntheses of different galloyl-lævoglucosanes, none of which have so far been found in nature. I have tested Professor Karrer's trigalloyllævoglucosane by the gold-beater skin test for tannins which has been worked out in this laboratory by Miss E. Atkinson and Miss E. O. Hazleton (*Biochem. Journ.*, 1922, **16**, 516) and I have convinced myself that Karrer's substance has no tanning properties. Mr. Woodroffe's optimism is obviously unfounded.—I am, Sir, etc.,

NEWS AND NOTES

FRANCE

The Nitrogen Industry

Since the article on the position of the nitrogen industry in France was published in these columns (Mar. 9, p. 228), further information has come to hand on the operation of the Claude processes at the Mines de Béthune. The coke-oven gas is tapped at the exit of the benzol scrubbers, compressed at 25 atm. and passed into a pressure column where the last traces of benzol are removed by a current of heavy oil, subsequently passing into a second column in which carbon dioxide is removed by lime water. The gas is then led to the separation apparatus, in which water and other condensible products, including ethylene, are removed. The hydrogen is then stored in a gasometer, but the remaining gases, which are rich in methane and yield 6000 cals., are utilised. From the gasometer the hydrogen is drawn by the hypercompressor at the same time as a suitable volume of air which is burnt before compression, and the mixture of nitrogen and hydrogen obtained is hypercompressed, passed through the purifying tube in which carbon monoxide is transformed into water and methane, and finally into the five catalyst tubes. The residual gases are returned to the hydrogen apparatus. From actual working the following figures have been obtained:—On treating 850 cb.m. of coke-oven gas per hour containing 49 per cent. hydrogen, a yield was obtained per hour of 425 cb.m. of gas containing 90 per cent. of hydrogen and 1·6 per cent. CO, the remainder consisting of nitrogen; 150 kg. of ammonia, of which 140 kg. was liquid, was produced per hour, and the total power consumption for heating, benzol removal, etc., was 460 kw.—*i.e.*, 3·06 kw.-hrs. per kg. of ammonia, 1·5 kw.-hrs. being required for the synthesis itself. The advantage of this procedure lies in more perfect recovery of the benzol, and the recovery of ethylene for the production of synthetic alcohol, of which 150 to 200 kg. is obtained per ton of ammonia. Recovery of these two products considerably reduces the cost per unit of nitrogen fixed. It is reported that a plant for treating 5000 cb.m. of gas per hour is under consideration for the manufacture of 20 metric tons of ammonia per day or 25,000 m.t. of ammonium sulphate annually. According to recent information on the Casale process, catalysis plant for producing 3 to 5 and 7 m.t. of ammonia per day has been established at the factory at Terni, in Italy. The hydrogen is produced by the electrolysis of water, a procedure which is economic under certain conditions, and a mixture of nitrogen and hydrogen is obtained by burning excess of hydrogen in air, water being eliminated as liquid. The pressure of the gas in the catalysis circuit is from 500 to 700 kg. per sq. cm., as compared with 200 kg. in the Haber and 1000 kg. in the Claude processes. The ammonia gas is liquefied by cooling, water not being used. An interesting point is that the gas is circulated by a pump through a single closed circuit and a single catalysis apparatus until transformation is complete. The French Cie. des Produits Chimique d'Alais, Troyes et Camargue, is installing plant to exploit this process, and further factories are said to be under consideration in Spain, Switzerland and Spain.

UNITED STATES

The Patent Office in 1922

During the year ended December 31, 1922, more than $3,000,000 was paid into the U.S. Patent Office by inventors and others, an increase of $237,000 over previous years. This increase was caused by a slight increase in fees charged and by the receipt of over 108,000 patent and trade-mark applications during the year; 88,930 applications for patents, reissue of patents and designs, and 173,932 amendments in pending applications having been filed. Inventors and attorneys were furnished with 72,626 photographic copies of drawings, and 186,129 photostat copies, for which $11,392.30 and $36,606.35 were received. Printed copies of specifications and drawings of patents to the number of 2,417,284 were sold at 10 cents each. The total number of printed copies of patents distributed during the year was 4,809,887.

GENERAL

Jâbir and Geber

In a recent number of *Nature* (Feb. 17, 1923), Prof. J. R. Partington discussed the identity of Geber, the reputed early Arabic chemical writer (whose identity with Jâbir was suggested by Mr. E. J. Holmyard in *Nature* of Oct. 28, 1922), and strongly criticised the attitude of Prof. E. O. von Lippmann in his *Entstehung etc. der Alchemie* with regard to the authenticity of the Latin works attributed to Geber. Prof. von Lippmann has now replied (*Chem.-Z.*, April 14, 1923), and claims that, so far from his method of argument being arbitrary and "untrustworthy," his conclusions have been arrived at inevitably, step by step, and have been favoured by eminent Orientalists. Prof. Partington's evidence for the authenticity of Geber's (pseudo-Geber's) works, based on Boerhaave's *Elementa Chemiae*, is considered unconvincing, and the comparison between the *De Anima* and *Canon* of Avicenna and Newton's *Daniel* and *Principia* quite unjustifiable. The facts remain that there is no Arabic MS. of Geber extant, that no Arab of that or a later period possessed a comprehensive chemical knowledge, and that the form of the Latin "translations" bears the stamp of the schoolmen of 1250–1300, Latin MSS. of a prior date not being extant. Concluding with a reference to the latest treatise of Darmstaedter, Prof. von Lippmann invites his critic to prove the existence of the spectre which he claims to see.

LEGAL INTELLIGENCE

The Carriage of Zinc Ash. A. Brandt and Co., and F. W. Vogel and Co. *v.* The River Plate Steam Navigation Co.

An action was heard by Mr. Justice Greer on April 25, in the King's Bench Division in which A. Brandt and Co., London, and F. W. Vogel and Co., Buenos Ayres, sued the River Plate Steam Navigation Co. for damages for breach of contract to carry a cargo of zinc ash from Buenos Ayres. After loading the zinc ash showed signs of heating; it was therefore unloaded and afterwards re-dried and reconditioned, the allegation being that it was wet when shipped. The defence was that there was justification in removing the cargo as it was dangerous as the heat generated was 160° F.

Mr. Knight, F.I.C., of Liverpool, said that he did not think there was any danger of spontaneous combustion; had he found zinc ash in the hold heating to the extent indicated, he would have advised its removal. Zinc ash might become dangerous and produce an explosion.

Mr. F. W. Harbord said that heat would be evolved when moisture and finely-divided zinc came in contact. The bags were rotted by chemical action, and not charred; if the ash contained much very finely-divided metallic zinc it might generate sufficient heat to damage or be a source of danger to any organic material. If the bags burst, as they would if they were rotten, there would be danger that the bales of cotton in the cargo might be ruined, as the ash contained zinc chloride, which would char cotton. Assuming that large quantities of hydrogen gas had been produced, there would be danger from the introduction of a naked light, but no danger of spontaneous combustion from the heat developed.

In delivering judgment, Mr. Justice Greer said he was satisfied that the zinc ash was dry at the time it left Messrs. Vogel's warehouse, and that some of the bags, which were the cause of the subsequent trouble, were wet through delivery on a wet day, but none of the bags afterwards found to be damaged became wet after delivery to the ship. The temperature might, through oxidation, have been raised so greatly as to cause the bags to be so damaged, that the zinc might have escaped during the voyage and damaged the surrounding cargo, but in no case was there any danger of spontaneous combustion. There would, however, have been grave risk of the contents escaping on the voyage and causing damage to cotton and cottonseed in the hold. More bags than was necessary were removed from the ship, and there was unreasonable delay in reconditioning and reshipping the unshipped bags. Judgment was given for Messrs. Brandt for £748, money paid by them under protest, damages for the breach to be assessed by the referee. The claim by Messrs. Vogel was dismissed without costs.

REVIEWS

Weyls Methoden der Organischen Chemie. *By* Prof. J. Houben. *Vol. II. Pp. xxviii*+1115. *Second edition, revised and enlarged. Georg Thieme,* 1923. *Price: paper,* 33*s.*; *bound,* 36*s.*

The second edition of the first volume has already been reviewed in these pages (1922, 141 R), and it is only necessary, therefore, to explain the scope and character of the second volume.

Briefly, it deals with the reagents and reactions of organic chemistry and is divided into sections. Each section is compiled by an author of established reputation, generally, though not invariably, with characteristic precision and thoroughness. Thus oxidation and reduction are very fully treated by Dr. Stoermer, esterification and hydrolysis by Dr. Hess, condensation by Dr. Kempf, and so forth. Not only are the individual processes described and examples quoted *in extenso,* but the preparation of the necessary reagents, both organic and inorganic, is also given—all with full references to the literature.

Each new section is introduced with a general outline of the process, its application and, where necessary, an account of any special apparatus, and it is rounded off at the end with a tabular statement of a list of the reagents described. Thus the volume forms a compendium of practical information to which every organic chemist may turn for an account of many of the chief laboratory processes. It should be pointed out, however, that the sections are by no means of equal merit. The first two or three chapters and the last on the action of light are brought well up to date. The last-named contains a very full and interesting account of much recent work, especially by Ciamician and Silber and other Italian chemists, and by Stoermer and Stobbe in Germany, and is introduced by a description of the various forms of lamps and apparatus used in this branch of research which the writer has not seen elsewhere. Perhaps the least satisfactory sections are those on electrochemical processes, enzyme action and the resolution of optical isomerides, which are not only incomplete in point of matter, but which ignore important work derived from non-German sources. For example, we are informed in a footnote to the section on fermentation enzymes that the most important work on the subject has appeared in the German "Berichte," whilst the work of Harden and his collaborators is dismissed in five lines. Again, in the table giving a list of the resolution of asymmetric amines, no mention is made of the exhaustive researches of H. O. Jones, whose name does not even appear in the index, and only one example is given of Kipping's resolution of the asymmetric silicane compounds. The omission of the names of Crum Brown and Walker under the electrolysis of the salts of organic acids is another curious instance of the same kind, whilst the persistence in attributing the discovery of the aluminium mercury couple to H. Wislicenus, though described by him many years after its description and use in this country, is another example of either ignorance of the facts or their intentional omission.

J. B. Cohen

Crystallisation of Metals. *By* Col. N. T. Belaiew, C.B. *Pp.* 143. *London: University of London Press,* 1923. *Price* 7*s.* 6*d. net.*

Col. Belaiew, whose name is well known in this country as an investigator who has continued the work of Prof. Tschernoff in the study of the structure of metals, has now printed the substance of a course of lectures delivered by him at the Imperial College last year, Prof. Carpenter contributing a preface. The subject is divided into the study of crystallisation from the molten state, crystallisation from the solid state, the formation of eutectics and eutectoids, and structural equilibrium in solids, most of the examples being drawn from the steels. The author's earlier memoir, which contains the results of most patient investigations into the crystallisation of slowly cooled masses of high carbon steels, was only published in the Russian language, and has therefore been inaccessible to most metallurgists except in the form of abstracts. The principal facts and illustrations are now reproduced, with a lucid explanation of the main features of the process. The author is particularly interested in the geometrical relations of the constituents of metallic masses, and therefore treats of the growth of crystallites, the relation of macro- and micro-structure, Widmanstätten figures, and the shape of crystal grains, subjects which are ordinarily omitted from the orthodox treatises on crystallography, whilst he uses the principles established by the crystallographers to co-ordinate his facts. The result is a fresh and highly interesting volume, which can be read and understood by every metallurgist and by most physical chemists. The constitution of the pearlite grain, a subject recently discussed by Col. Belaiew in a paper read before the Iron and Steel Institute, is shown by geometrical diagrams and by some beautiful photographs at high magnifications. The damascened steels afford other striking examples of crystallisation and segregation or coalescence. Throughout the book, indeed, the beauty of the illustrations is remarkable, and evidences the skill of the author and of his colleague, Capt. Brandt, in the manipulation of the microscope. The importance of crystallisation in metallurgy is great, and it will be of assistance to many to have so clear a presentation of the main facts placed before them.

C. H. Desch

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for May* 10)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Belgium ..	Pharmaceutical specialities	601
Canada ..	Drug specialities ..	597
Italy	Aluminium, nickel, tin, zinc, copper, brass, antimony, lead	605
,, ...	Shellac, gum arabic, medicinal herbs and plants ..	606
,, ...	Electrical cables ..	19365/F.W./C.C.
Netherlands ..	Iron tubes and fittings	852/3/F.G./E.C./2
New Zealand ..	Drugs, photographic materials	596
Rumania ..	Emery wheels (tender)	10578/F.E./E.C./2
South Africa ..	Copper tubing (tender)	11196/E.D./E.C.
Sweden ..	Chemical products and dyestuffs for the wood pulp, paper and glass industries	613, 614
United States	Asbestos and asbestos products	18655/F.W./M.C./2

TARIFF CUSTOMS EXCISE

Australia.—The operation of the duty on writing and typewriting paper has been deferred until January 1, 1924.

Czechoslovakia.—The Commercial Convention with the Netherlands is now in force.

Costa Rica.—The issue of May 10 gives a list of duties on various lighting materials.

Eucador.—The export of sugar had been prohibited.

Italy.—A general stamp tax has been levied on the transfer of the ownership of certain goods, including scrap metal, chalk, lime, cement, chemicals, fertilisers, resins and medicinal specialities. The duty on petroleum imported for agricultural machinery has been reduced to 10 lire (gold) per 100 kg.

Kedah.—Manufactured rubber goods are exempted from export duty.

South-West Africa.—Sugar may not be imported except under permit.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Mines (Working Facilities and Support Bill)

In moving the second reading of this Bill Lt.-Col. Lane-Fox said that the Bill was to secure the most effective development of the national mineral resources. It represented a valuable agreement between conflicting interests and should have enabled large properties of minerals to be worked. The second reading was carried by 214 votes to 76.—(May 7.)

Applications for Patents

Viscount Wolmer, answering Mr. Ede, said that 6000 applications for patents were awaiting examination in the Patent Office. This congestion was due chiefly to arrears caused by the war and to the revival of foreign applications after the war. He hoped that the return to normal conditions would be soon accomplished. —(May 8.)

Anglo-Persian Oil Co.

In answer to Mr. Potts, Mr. Baldwin said that of the share capital of 20,000,000 £1 shares in this company, the Government held 5,000,000 in addition to 1000 £1 8 per cent. cumulative first preference shares, and £199,000 in 5 per cent. debentures. The net profit during 1922 was £2,730,381, compared with £4,028,022 in 1921.—(May 8.)

International Labour Conference

In moving approval of the Government's policy respecting the Draft Convention's recommendations adopted by the International Labour Conference held at Geneva in 1921-22, Sir Montague Barlow referred to the Draft Convention relating to the use of white lead in painting. The Convention was passed owing to the influence of the British delegates, but the vote was given solely on the basis that the Convention should prove satisfactory and acceptable to all. In its wide outlines the Convention prohibited the use of white lead or lead sulphate in the internal painting of buildings, and the employment of males under 18 years of age, and of all females in any painting work of an industrial character involving the use of white lead. These provisions, however, were not to come into force until November 20, 1927. Further regulations controlled the conditions under which white lead could be used. Since then, difficulty had been found in interpreting the phrase "work of an industrial character" and the report of the Norman Committee (*cf. Chem. & Ind. p.* 377, 1923) indicated that in view of recent discoveries, some of the restrictions embodied in the Draft Convention, were no longer so important as they were. The matter therefore, called for further consideration, and it was proposed to communicate with the Authorities at Geneva whilst the Home Secretary would confer on the matter with the interests affected.—(May 9.)

REPORT

REPORT ON THE ECONOMIC CONDITIONS IN CUBA, DATED SEPTEMBER, 1922. *By* G. HAGGARD, *H.M. Consul-General, Havana, and* D. GAINER, *H.M. Vice-Consul, Havana. Pp.* 20. *Department of Overseas Trade. H.M. Stationery Office,* 1922. *Price 9d.*

The economic, political and geographical ties of Cuba are mainly with the United States, a dependency which is well illustrated by the trade statistics. Following the slump in sugar in 1920 the 1921 crop of 3,922,267 tons was thrown on to the market, causing worse confusion. The Government took control of sales till December, 1921, after which the demand improved, and the price obtaining at the time of issue of the report (3¾ cents per lb.) gave rise to general optimism. Up to the end of July, 1922, there had been shipped 4,099,305 tons, of which the United States took 74 per cent. The tobacco industry also suffered greatly during the year; between January 1 and August 31, 1921, 172,683 bales of tobacco were exported, whereas in the same period of 1922 the amount was 235,333 bales. Industrial alcohol has been exciting much attention in Cuba recently (*cf* J., 1922, 570 R), the raw material being molasses, a cheap by-product of the sugar industry. Much denatured spirit is used in motor vehicles, and it is hoped eventually to render Cuba independent of imported supplies of petrol. According to recent statistics the output of local distilleries other than those attached to sugar factories is 6½ million gallons, which is mainly exported. There are several soap works on the island. Brewing is carried on, though Canadian and British beers are also imported. There are large henequen (Mexican agave) plantations, and in the fiscal year ending June 30, 1920, apart from local requirements, cordage manufactured from this product was exported to the United States to the value of $200,604.

Mineral exploitation is not extensive; there is an output of about 1,000,000 tons of iron ore per annum, and the latest figures show an export of 42,000 tons of copper ore. Manganese and chromium ores are worked on a small scale and gold is also found. There are British controlled asphalt deposits near Mariel which are capable of important development. The total exports for the year ending June 30, 1920, were valued at $855,138,341 and for the corresponding period of 1920–21 at $395,914,577. Of the latter figure the United States took 85·2 per cent., and the United Kingdom 5·9 per cent. The imports in 1919–20 amounted to $356,435,099 and in 1920–21 to $278,130,740, of which the United States supplied 78·0 per cent. and the United Kingdom 9·8 per cent. It is anticipated that projected tariff revisions will affect British trade adversely in a number of articles, including soap, alcoholic beverages, textiles, etc.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

With the exception of a reduction in the price of Sodium Sulphite (pea crystals) there are no changes to report in this section.

Acetic Acid, 40% tech. ..	£24 per ton.
Acid Hydrochloric ..	4s.-5s. per carboy d/d.
Acid Nitric 80° Tw. ..	£24 10s. per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d.-£8 per ton.
Arsenic (White) ..	£70-£75 per ton.
Bleaching Powder ..	Spot £11 7s. 6d. d/d. Contract £10 7s. 6d. d/d.
Bisulphite of Lime ..	£7 per ton, packages extra.
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Copper Sulphate ..	£27 per ton
Potash Caustic	£35-£36 per ton
Potass. Bichromate ..	5¾d.-6d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b.
Soda Caustic 76% ..	£20-£21 per ton.
Soda Crystals	£5 10s. per ton.
Sod. Acetate 97/98% ..	£26 per ton.
Sod. Bicarbonate ..	£10 10s. per ton.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	2⅞d.-3d. per lb.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, conc. ..	£16 per ton carr. paid.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide ..	5s. 9d. per lb.
Carbon Bisulphide ..	£26-£28 per ton according to quantity.
Carbon Black	1s. 5½d. per lb. ex wharf. Still very scarce.
Chromium Oxide ..	1s. 5d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb. Firmer on advance in price of Rape Seed Oil.
Lead Hyposulphite ..	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood-distillation products. Grey Acetate of Lime has advanced in price.

Acetate of Lime—	
Brown	£10 15s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 10s. per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 9d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 10s. per ton d/d.
Brown Sugar of Lead	£43 5s. per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 5d. per lb. Little movement in the market.
Crude 60's	3s. 6d.-3s. 9d. per gall. Market weaker.
Acid Cresylic—97/99	2s. 2d.-2s. 5d. per gall. Market quiet.
Pale 95%	2s.-2s. 4d. per gall. Not much demand.
Dark	1s. 10d.-2s. 0½d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	9½d.-10d. per gall. Not much demand.
Unstrained	9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8½d. per gall. Business slack, abundant supplies.
Pure	2s.-2s. 2d. per gall.
Toluole—90%	1s. 9d.-2s. per gall.
Pure	2s.-2s. 6d. per gall. Not much inquiry.
Xylol	3s.-4s. per gall. according to quality.
Creosote—	
Cresylic 20/24%	11½d.-1s. per gall. Not much business.
Middle Oil	8½d.-9½d. per gall Market steady.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d.-9¼d. per gall.
Solvent 90/160	1s. 7d.-1s. 9d. per gall. Fewer inquiries.
Solvent 90/190	1s. 5d.-1s. 8d. per gall. Market steady.
Naphthalene Crude—	
Drained Creosote Salts	£7-£8 per ton.
Whizzed or hot pressed	£11-£14 per ton.
Naphthalene—	
Crystals	£18 per ton.
Flaked	£16 per ton.
Pitch, medium soft	No business for this season. Prices for Autumn delivery 140s.-150s. per ton.
Pyridine—90/140	11s.-12s. per gall.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

The recent improvement in the business done in Aniline Dyes reported previously is still maintained. Business is coming through rather more freely. This is rather surprising in view of the fact that the Textile Trade is very quiet and we must anticipate that when the Textile Trade improves, the Aniline Dyes Trade will be still better. Prices are firm without advance, but there is no likelihood of any fall for some little time forward.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
p-Dichlorbenzol	£70 per ton.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	4s. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works. Good demand.
Nitronaphthalene	1s. per lb. d/d.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80%	£50 per ton.
Acid, Acetyl Salicylic	3s. 2d.-3s. 3d. per lb. Steady.
Acid, Benzoic	2s. 6d. per lb. Still very scarce at this figure.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton. Prices reduced by £5 per ton.

Acid, Citric	1s. 9d. per lb., less 5%. Dearer; demand active; higher prices expected.
Acid, Gallic	3s. per lb.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb.
Acid, Salicylic	2s. 3d. per lb. still quoted.
Acid, Tannic	3s. 3d. per lb. Unchanged.
Acid, Tartaric	1s. 4d.-1s. 4½d. Demand continues to increase, and a period of hot weather should see a further rise in price. There is much more inquiry from the Continent and the U.S.A. and good business has been done for export.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d. per lb., without much movement.
Amidopyrin	13s. 6d. per lb. Unchanged.
Ammon. Carbonate B.P.	£37 10s. per ton.
Atropine Sulphate	12s. per oz.
Barbitone	Quoted up to 20s. per lb. Much firmer.
Benzonaphthol	4s. 6d. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Bromides	In steady demand without alteration in price.
Chloral Hydrate	4s. per lb. Price well maintained.
Chloroform	2s. 3d. per lb. for cwt. lots, ton lots being quoted down to 2s. per lb.
Creosote Carbonate	10s. per lb., with little enquiry.
Formaldehyde 40%	£90 per ton.
Guiacol Carbonate	8s. 6d. per lb. is the present value without any orders.
Hexamine	4s. 3d. per lb. Lower prices now quoted.
Homotropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. Market good with considerable inquiry.
Magnesium Carbonate—Light Commercial	£38 per ton nett.
Magnesium Oxide—Light Commercial	£85 per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Menthol	35s. per lb. spot. Advanced.
Methyl Salicylate	In a weaker position at 2s. 6d. per lb. for carboys.
Methyl Sulphonal	14s. 6d. per lb.
Mercurials	Unchanged. Market quiet.
Paraformaldehyde	4s. Neglected.
Paraldehyde	1s. 7d. per lb.
Phenacetin	6s. 6d. per lb. spot value. In good demand at this figure.
Phenazone	7s. 6d. per lb.
Phenolphthalein	5s. 6d. per lb. Much firmer.
Potass. Bitartrate—99/100% (Cream of Tartar)	98s. per cwt., less 2½%. Firmer.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. Demand still continues good.
Potass. Permanganate	10½d. per lb. Market less firm.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Salol	3s. per lb. still asked.
Sod. Benzoate	2s. 6d. per lb. Very firmly held.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality. Demand improving and considerable business being done.
Sod. Hyposulphite—Photographic	£15-£17 per ton, according to quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d. per cwt. Fairly good demand.
Sod. Salicylate	In good supply. Values unaltered, being 2s. 9d. per lb. for Powder, 2s. 11d. per lb. for Crystal.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. per ton, according to quantity for home trade, 1-cwt. packages included.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.
Thymol	Present value of good white from agowan seed is 17s. per lb.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	8s. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	4s. 3d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	3s. ,, ,,
Benzyl Benzoate	3s. ,, ,,
Cinnamic Aldehyde	14s. 9d. ,, ,,
Coumarin	16s. 3d. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	15s. ,, ,,
Ethyl Phthalate	4s. 3d. ,, ,,
Eugenol	11s. 6d. ,, ,,
Geraniol (Palmarosa)	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	16s. 6d. ,, ,,
Linalol ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	25s. 6d. ,, ,,
Methyl Anthranilate	6s. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Xylol	9s. 6d. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Safrol	3s. 3d. ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	23s.-24s. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	2s. ,, ,,
Bergamot Oil	12s. 6d. ,, ,, spot.
Bourbon Geranium Oil	31s. 6d. ,, ,,
Cananga Oil, Java	9s. ,, ,,
Cinnamon Oil, Leaf	4½d. per oz.
Cassia Oil 80/85%	8s. 6d. per lb.

Citronella Oil—	
Java 85/90% ..	4s. 2d. ,, ,,
Ceylon..	3s. 3d. ,, ,,
Clove Oil..	8s.-8s. 6d. per lb.
Eucalyptus Oil 70/75%	1s. 9d. per lb.
Lavender Oil, Mont Blanc 38/40% ..	13s. ,, ,,
Lemon Oil	3s. 1d. ,, ,,
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet ..	11s. 6d. per lb.
Otto of Rose Oil—	
Anatolian	24s. per oz.
Bulgarian	30s. per oz.
Palma Rosa Oil ..	17s. 6d. per lb.
Peppermint Oil—	
English	80s. ,, ,,
Wayne County ..	13s. ,, ,,
Japanese	6s. 4½d. per lb.
Petitgrain Oil	8s. 3d. ,, ,,

TRADE NOTES

Dyestuffs (Import Regulation) Act

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during April has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee:—

The total number of applications received during the month was 512, of which 430 were from merchants and dealers. To these should be added 22 cases outstanding on April 1, making a total of 534 for the month. These were dealt with as follows:—Granted: 331 (of which 318 were dealt with within 7 days of receipt). Referred to British makers of similar products: 130 (of which 121 were dealt with within 7 days of receipt). Referred to Reparation Supplies available: 56 (all dealt with within 2 days of receipt). Outstanding on April 30: 17. Of the total number, 534, of applications received, 479, or 90 per cent., were dealt with within 4 days of receipt.

British Chemical and Dyestuffs Traders' Association

It is announced that the British Chemical Trade Association has amalgamated with the Chemical and Dyestuffs Traders' Association to form the above Association. Mr. Victor Blagden (Victor Blagden and Co., Ltd., London) is the Chairman of the new organisation, and the remainder of the executive are as follows:—Vice-chairman, Mr. F. T. T. Reynolds (Millwards Merchandise, Ltd., Manchester); Hon. Treasurer, Mr. W. Waugh (Walter Waugh and Co., London). *Executive Committee*: Mr. H. A. Berens (Old Strand Chemical and Trading Co., Ltd., London); Mr. A. F. Butler (R. W. Greeff and Co., Ltd., London); Mr. A. Connell (A. Connell and Co., London); Mr. H. Gilliat (E. G. Jepson and Co., Leeds); Mr. G. A. Hamilton (A. and M. Zimmermann, Ltd., London); Mr. T. Henderson (T. Henderson and Co., Ltd., Glasgow); Mr. S. J. C. Mason (Bush, Beach and Gent, Ltd., London); Mr. C. Page (Chas. Page and Co., Ltd., London); Mr. H. S. Willcocks (H. S. Willcocks and Co. (Chemicals), Ltd., Manchester). The offices of the Association will be at 80, Fenchurch Street, E.C. 3 (Telephone: Avenue 7347), and the Secretary will be Mr. O. F. C. Bromfield, Secretary to the late British Chemical Trade Association.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, MAY 25, 1923 No. 21

EDITORIAL

THE meeting of the Union Internationale at Cambridge seems likely to be well attended. Among the French delegates are included Professors Moureu, Béhal, Boudouard, Haller, Lindet, Etienne, Le Chatelier and Blaise, and Messrs. Kestner, Kling, Marie, Gérard, Nicolardot, Matignon, Bordas and Grignard. America is sending among others Professors Bancroft, Lewis, Noyes and Hibbert, and Messrs. Washburn, Zanetti and Howe. The Italian delegation includes Dr. Conti Ginori, Prof. Nasini, Senator Paternò, Signori Delfino and Pomilio; the Czecho-Slovakian includes Prof. Vesely, the Polish Profs. Marchlewski, Bielecki, Swietoslawski and Trepka. Spain is sending Profs. Fernandez, Giral, Moles and Mourelo, Denmark is sending Profs. Bjerrum, Bronsted, Jacobsen and Biilmann and Mr. Kai Warming. Prof. Minovici is coming from Rumania, Prof. Bodtker from Norway, and Prof. Read from Australia. Altogether at least a hundred delegates are expected, and as a number of controversial topics are to be discussed, we may expect to find distinguished chemists in every street, maintaining with no little heat, their various opinions. The beauty of Cambridge, its interesting historic associations and its mediæval air make it singularly suitable for such a Congress.

* * *

The delegates will be received by Sir Charles and Lady Walston on Sunday, June 17th, at 4 p.m., at Newton Hall, and in the evening by the President and the British Federal Council. On Monday, June 18th, there will be Council and Committee Meetings, and at 4.30 p.m. the discussion of Prof. McBain's report on "The Nature of Soap Solutions"; in the evening a reception by the Master of Sidney Sussex College and Mrs. Weekes. On Tuesday, Council and Committee meetings, at noon the discussion of Dr. Rideal's report on "Recent Developments in Contact Catalysis," at 5.30 p.m., the discussion of Prof. J. F. Thorpe's report on "New Aspects of Tautomerism," then tea in the charming gardens of Sidney Sussex College, and at 8 o'clock the Annual Dinner in the Hall of Trinity College. On Wednesday, after the Council Meeting, there will be a discussion of Prof. Gowland Hopkins' report on "Chemical Mechanisms involved in the Oxidations which Occur in Living Tissues." This will be followed by the presentation of a very few Honorary Degrees to some distinguished foreign visitors and a reception by the Vice-Chancellor of the University at the Fitzwilliam Museum, and as the delegates leave and the Conference breaks up—which is what the Greeks meant by catalysis—the members of the Society of Chemical Industry will assemble for their own meeting. Cambridge will be full of interest for chemists during that week, and how many valuable discussions will take place during the short journeys between the Arts School, the Senate House, Trinity, King's, and the other colleges. *Plurimi transibunt et augebitur scientia* says the Vulgate, unless our memory is at fault, which signifies, "Many shall walk to and fro, and knowledge shall be increased."

* * *

Chemical Engineering appears to have made rapid strides in the United States. Here we announce with some self-satisfaction the foundation of a chair of chemical engineering at University College, London. The University of Michigan has recently sent us a note of the department of chemical engineering at Ann Arbour, from which it seems that the department includes three professors of chemical engineering, one of metallurgical engineering and a large number of assistant professors and instructors in these two subjects. The chemical engineering laboratories, which are to be opened next September, will occupy an area exceeding 40,000 square feet, with special facilities for studying evaporation, distillation, gas absorption, filtration, drying and crystallising; in addition there are special metallurgical, cement, ceramics, pulp and paper laboratories and other laboratories specially devised for investigating petroleums, motor fuels, gas and fuel. This appears to be the finest laboratory of the kind in any country, and we shall expect to receive much valuable information from the researches to be undertaken in it.

* * *

We are informed by the American Chemical News Service that catalysis is now to be applied to internal combustion engines. Dr. Edward Sokal, of New York, claims that greatly improved combustion is obtained by painting the interior of the cylinder head or firing chamber with a refractory paint containing a catalyst whose composition is not yet disclosed. This catalyst will accelerate the explosion and, according to the news circulated by the American Chemical Society, tests made on various types of automobiles show that an increase in power is obtained and an examination of the exhaust gases shows that the combustion is more complete. The progress of the internal combustion engine is a remarkable instance of the manner in which scientific discoveries can bring about new industries. Motor cars and aeroplanes will, no doubt, in the future, show yet further evidence of the practical utility of every branch of science and among these chemistry will be of supreme importance. The whole question of combustion is being studied by new methods; the nature of the chemical reaction of mixed gases may at any moment receive some explanation which will lead to surprising developments, and any new discovery which will effect economies in the production of power will be followed with great interest.

* * *

The University of London announces a course of three lectures on "The Structure and Behaviour of the Molecule," to be delivered by Prof. Gilbert N. Lewis, of the University of California. The lectures will be given at University College, London, at 5 o'clock on Wednesday, June 6th, Friday, June 8th, and Tuesday, June 12th, and are addressed to advanced students and others who may be interested. No ticket is required for admission. Professor Lewis's work is well known in this country, although perhaps full justice has not been done to him by many casual readers of the new theories of the structure of the atom. He it was who first worked out a really clear conception of an octet to explain the chemical activities of an electronic atom, and but for his work the more recent hypotheses of Langmuir, Bohr, Dauvillier and others would have been less easily understood and less widely known. Of the three lectures mentioned above the first is on "The Structure of the Molecule," the second on "The Colour of Substances," and the last on "The Sources of Chemical Affinity."

CHEMISTRY—THE KEY TO INTERNATIONAL RELATIONS

By H. E. HOWE

For the most part international relations grow out of efforts to improve the status of a country either as regards the physical or financial well-being of the people. These two considerations are basic, although they are to be found in many forms all along the path of history. The enforced territorial expansion of a country, while primarily to permit peoples to go out from centres of great concentration of population, in the end means that a greater quantity of natural resources must be found. Whereas the craving for power may sometimes appear to be at the base of international relations, even this may be translated into such terms as the exploitation of conquered peoples or other forms of gain which may be described in terms of physical or financial well-being.

Only in comparatively recent times has the physical well-being of a people become a prime consideration. Assistance in overcoming a plague or epidemic, relief in times of famine, and the defence of weaker peoples against oppression have become more common phases of international relations since the days of republics. Indeed, republics themselves are the result of the effort to further the interests of the people as a whole as opposed to a ruling class.

The control of natural resources, which is desirable in peace and vital in war, may be said after all to be the basis of most international dealings. A nation seeking power in commerce or an impregnable position in war directs attention to natural resources of present value and future application. Natural resources and their development always involve chemistry, since chemistry is the science which concerns itself with the characteristics and properties of materials under all varieties of conditions. The resources themselves may be expressed in terms of chemical compounds, and before they can be economically utilised chemical research and technology is invariably called in. It is but a step to those processes through which raw materials for particular commercial uses are changed to meet new sets of specifications and materials are synthesised in the laboratory to make available in commercial quantities compounds nowhere to be found in Nature.

That nation, therefore, which pays the greatest attention to the development of chemistry and its application to the arts may well be said to occupy a commanding position in international affairs. A knowledge of substances and how best to use them for given purposes may be even more important than the ownership of the resources themselves. To prove this may be cited the refining of tungsten from its ores and the separation of radium from carnotite. In both these instances countries without the raw materials gained a commanding position through research and development, so that ores were sent to them to be refined instead of the knowledge of how this was done being transmitted to the sources of supply. Let us examine history and see what examples of international relations to which chemistry has been the key may be found to support this premise, and to show how the advantage has shifted, now to this nation and now to that, depending upon scientific work and principally work in chemistry.

One of the earliest severe strains upon international relations came about through the loss by storm at sea of three cargoes of those chemical substances known as spices and perfumes. A world-wide panic ensued, and while, to be sure, it was a financial panic, it must not be forgotten that finance is, after all, closely related to and at times dependent upon chemical development. In this instance a bank at Athens had loaned great sums to those engaged in the importation of these small cargoes. Then, as to-day, banking was conducted co-operatively by the banks all over the known world. The total loss represented by the sinking of the ships made it necessary for the bank at Athens to call upon its correspondents, and they in turn upon their correspondents, until Rome itself felt the pressure. It so happened that at this time a decree by the Roman Emperor had directed the financiers of the day to invest a certain large percentage of their funds in agricultural development, and much money had been withdrawn from the banks for this purpose. It was not a simple matter to have this money immediately deposited again, and the emperor was off on a hunting trip. Things became very acute before the end of the ten days necessary to secure his return, and only when the edict was rescinded and much of the emperor's wealth made available, did the financial world get on its feet again. People are prone to forget that the absolute destruction of a great mass of wealth at any place or at any time is a serious thing, and can be replaced only by an amount of labour usually in excess of that required to create the wealth destroyed.

The wealth and power of those ancient cities, Carthage and Tyre, which were comparable to at least the smaller countries of our day, were based upon a chemical compound found in minute quantities in the dorsal vein of a snail-like shellfish called *Murex*. One may easily imagine the hazards involved in collecting a quantity of molluscs from each of which no more than a few drops of a mucilaginous fluid could be obtained. When this fluid was put upon fabric or leather and exposed to air and sunlight the famous Tyrian purple was formed. In fastness to light and washing, in brilliancy and uniformity, its colour did not compare with modern indigoes, yet its value may be realised from the fact that the Emperor Hadrian is reported to have refused his wife a purple gown because of its extreme costliness. It is interesting to note that to this day isolated villages about the Mediterranean use this same fluid from the shellfish in dyeing fabric.

Feats of old, like the use of Greek fire and numerous devices employed in the defence of Constantinople, gave temporary advantages to those who had this special knowledge. The conquerors of old employed engineering at every turn, and those who developed the blades of Toledo and Damascus by processes now known to have been chemical, though not so recognised then, had an advantage over adversaries comparable with that gained by the first man who found out how to make metal into a weapon for use against the clubs of his adversary. In those days, when there was no such thing as systematic research and investigation, even the most observing men were dependent upon chance for such valuable discoveries. To this day people believe that the art of hardening copper has been lost for ever, and scarcely a week goes by without some clever man offering to sell to our great metal concerns the secret which he has rediscovered. Science has not answered all the questions of the ages, but the scientific method has nearly always been able to find causes, break problems into component parts, and solve them so that conditions for production may be satisfactorily duplicated.

The balance of power was at once disturbed when the chemical compound gunpowder was invented. Gunpowder thus became a new factor in international relations. Subsequently that nation which controlled the raw materials for explosives could dictate to a large degree how things were to be. A fundamental material in the manufacture of all explosives is nitric acid, and a source of nitrates became the thing greatly to be desired. From the time of the invention of gunpowder until the middle of the nineteenth century, Indian saltpetre was the only known available source of the element nitrogen, in a form which could be used for nitric acid. These Indian resources were in the form of potassium nitrate, and had been deposited in the soil or rocks through the action of nitrifying bacteria. When potassium salts are present, potassium nitrate is produced, but the native nitre usually consists of calcium nitrate and some magnesium nitrate. Where there is no excess of rain, the soil moisture brings the solution of these soluble nitrates to the surface, where they are deposited as an efflorescence as the water evaporates. Obviously the amount of nitre procurable from natural deposits and formed under natural conditions is very limited, and as the demand for saltpetre increased other sources of supply were sought. Following the principles that had been observed from the formation of natural deposits, nitrate plantations were established in many countries where nitrates were slowly formed and protected from the weather. The plantations of Hungary, Switzerland, France, and Sweden have been described in detail in the literature. Resort to the same methods was had by the Confederacy during the Civil War. In emergencies, as in Sweden in 1520, even the earth of cemeteries was lixiviated to obtain nitre, and at one time Sweden imposed a tax which had to be paid not in money but in saltpeter. About 1821 the immense deposits of sodium nitrate in South America were discovered. The deposits extend for some 450 miles north and south in the arid plains between the Andes Mountains and the coastal range on the Pacific, at distances of from 15 to 93 miles from the sea, and at altitudes of from 3600 to 13,000 feet; and exploitation has proceeded rapidly. Some years ago the exhaustion of the Chilean nitrate was forecast, and when Sir William Crookes predicted the possible starvation of the earth, he pointed out that the yield of wheat could be increased from an average of 12·7 bushels per acre to 20 bushels or more by the use of 150 pounds of nitrate of soda on each acre annually. He then went on to say that if this practice should be widely adopted and the whole area under cultivation be treated at the proposed rate, the Chilean deposits would be exhausted in four years. It now appears that these estimates were based upon then known deposits which were only a fraction of the actual deposits in Chile. In addition to this, there have been perfected processes for recovering nitrates from low grade ores that had not previously been worked. It is now estimated that at a rate of consumption of five million tons annually, the Chilean nitrate should last some three hundred years.

However, Chile is at a considerable distance from many nations which have found nitrate an essential in their world progress. Lines of supply in war time always present a difficult problem, and if such an essential material must always be brought overseas, the problem becomes further complicated. While great navies have been maintained for the protection of merchant shipping and of nationals at great distances from home, the nitrate situation has doubtless played a commanding part in the formation of an extended naval programme. It therefore became a scientific problem of world importance—how to make available the tremendous quantity of nitrogen present in the atmosphere. It has been estimated that the air over each acre of earth contains 33,880 tons of nitrogen, but to all intents and purposes this nitrogen is inert, since plants and animals can utilise it only when formed into nitrogen compounds.

For many years experiments have been conducted in an effort to find a way to fix this nitrogen. The early researches were of a purely scientific nature, and Priestley more than a hundred years ago found that by passing an electric spark through an atmosphere of nitrogen he could obtain traces of the oxides of nitrogen. Without giving all the historical details, it may be pointed out that the cheap water power of Norway enabled that nation to obtain something of an advantage when it was found that the nitrogen of the air could be oxidised by great electric arcs and recovered as nitric acid, although usually sold as calcium nitrate. The efficiency of the process was low, but hydroelectric power was extremely cheap, and the advantages gained were well worth the energy expended. Nations of Europe with military tendencies at once became interested in Norway, and took pains to acquire large financial interests in the Norwegian companies. Other scientists took up experiments in this field in the hope that they might find still more efficient methods. Great plants for the fixation of nitrogen by the cyanamide method sprang up in Norway and on other parts of the Continent, and became factors of no mean importance in international relations.

It was only a little more than ten years ago, when the Eighth International Congress of Applied Chemistry met in the United States, that we were given our first information of the success of experiments carried on by Haber at the expense of the Badische Anilin und Soda Fabrik. It was demonstrated that, in the presence of a catalyst, nitrogen and hydrogen could be caused to unite to form ammonia. We have since been told that the world war would have been begun earlier but for the fact that the Haber plants were not quite ready to meet the demand of Germany for military nitrates. It is interesting to note that to-day a smaller Germany is capable of producing 500,000 tons yearly, which is more than twice the nitrates which the old empire consumed annually for all purposes. English experts have not hesitated to sound a warning based upon this over-development of nitrogen fixation plants. The importation of Chilean nitrate by Germany is looked upon as a wholly commercial move designed to retain the good will of Chile and to take in return for German products the raw materials which Chile is in position to export.

The early methods for the fixation of nitrogen required great blocks of electric power, but much less power is needed to-day. The Haber process is operated at a pressure of 100 atmospheres and a high temperature. However, the recent work of Claude in France indicates that at still greater pressures, indeed up to 1000 atmospheres per square inch, the fixation is not only more rapid but the yield greater, and deterioration of the catalyst much retarded. The capital investment in large apparatus is reduced, for at this pressure much smaller vessels may be used and the larger units are a disadvantage rather than otherwise. The possibility, under present methods, of operating small plants may again shift to other lands the advantages derived from the fixation of atmospheric nitrogen. There are several industries where hydrogen is a waste product, and where it is purer than that prepared solely for the fixation of nitrogen by the synthesis of ammonia. In a Haber type plant nearly 70 per cent. of the operating cost is charged to the purification of gases. Obviously, if nitrogen fixation can be carried on in small units located where relatively pure hydrogen is available as a waste product, it will be a great step forward in the nitrogen problem. Nitrates are essential in food production, and while it is doubtful whether, under present conditions, nitrogen from the air can be fixed at a price to compete with Chilean nitrate, it is well to remember that in times of war, when costs are not considered, fixed nitrogen plants might be the salvation of a nation.

An advantage in world position has many times been lost because of the diligence of another nation in chemical research. We are indebted to necessities growing out of the Napoleonic wars for at least two important chemical developments. One of these is the production of sugar from beets. At a time when France was thoroughly blockaded and importation became next to an impossibility, the only source of sugar known was the cane of the tropical countries. The beets available did not contain more than five or six per cent. of sugar, and this was accompanied by so many foreign materials as greatly to reduce its purity. No doubt the first sugar from beets was far from satisfactory, but it was very much better than no sugar. The English sugar traders became alarmed and offered the French scientists sums large for those days to suspend their research, but all propositions were refused.

From that time the beet sugar industry has been developed not only in Europe but in the United States and Canada, and constitutes one of the best examples of what can be achieved through scientific selection. To-day whole crops of beets run well above 14 per cent. of sugar, with a purity that is quite satisfactory. Concurrently the scientific methods for extracting the sugar from the beet, purifying the sugar, and using the beet pulp and other waste products have gone forward. Whereas it once required beets from an acre to produce 300 pounds of commercial sugar, we now obtain 3600 pounds from the same area. Before the world war the production of beet sugar in the world had come to exceed that of cane sugar by several per cent., and from an importer of sugar France had become an exporter. A few years ago France exported as much as 250,000 tons annually.

Another invention resulting from the Napoleonic wars was Leblanc soda. Previously the important source of sodium carbonate was the native sesqui-carbonate of Egypt, Africa, and South America. Since the blockade prevented France from importing with any degree of certainty, Leblanc developed a process which is operating almost unchanged to this day, although it could not have persisted but for the market developed for hydrochloric acid, an important by-product of the process. This process has since been displaced to a large extent by the Solvay or ammonia soda process, which is based upon the fact that bicarbonate of ammonia is decomposed by a strong solution of sodium chloride or salt.

The siege of Paris gave us oleomargarine, which no doubt was a poor substitute for butter at the time, though none the less welcome. Since then margarine has become an important item of commerce. Dairy countries such as Holland and Denmark, and agricultural states like those of our Middle West, consume margarine in quantity. With the introduction of nutritious coconut oil into occidental diets, margarine is now made of wholesome vegetable oil churned in milk and often mixed with high grade butter in plants which are models of cleanliness. The one point of weakness has been the absence of that unidentified, unisolated, accessory food substance called fat-soluble vitamin A.

From the research now in progress we may expect the perfection of methods for preparing concentrated vitamins on a commercial scale which will make it possible to add them to otherwise satisfactory foods. This type of research is of utmost importance, not simply because of its relation to this one type of food but to others which, thanks to chemistry, can be prepared from staple raw materials. As a result of research, milk can be dried without affecting its physiological characteristics. This dry milk is soluble and may be stored for months without change. If the fat is first removed, the dry skim milk will keep indefinitely in tins. Neutral refined coconut fat can also be kept without developing rancidity for a long time. Since these two basic materials can be made into milk or cream, with practically any desired percentage of fat, where and when needed, they offer great advantages in transportation and storage, with a guarantee of quality and cleanliness difficult to obtain in many quarters of the earth, particularly the tropics. This type of food is wholesome and nutritious and satisfactory for adults. When chemical and biological research make it possible to add the fat-soluble vitamin, a food in every way equal to ordinary milk will be made available.

Nations also lose a world advantage when their scientists are compelled to go elsewhere for support in developing their discoveries to the commercial production stage. It was due to such causes that Germany had the opportunity to develop the dyestuff industry, and that the great Brunner-Mond establishment grew up in England. An effort to ruin England's West Indian trade by granting sugar bounties in France, Belgium, Germany and Russia forced England into industries using the cheap sugar of the Continent. Sugar-containing foods remained an item of English trade even after she again took up refining following the abolishment of the bounties in 1899.

(*To be continued*)

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

I OBSERVE

that all the best paragraphists occasionally take a holiday, and that although compelled by an unfeeling editor to supply their "copy" they are allowed somewhat more latitude while in the country doing their holiday task. In the intervals of sleeping, eating and a little golf I have been studying a bundle of papers which have accumulated on a subject which I have been wanting to look into for some time. At the present time it seems to me we are on the eve of big changes in the World's business and it behoves us to study every bit of information we can obtain. International Commerce is finding the old channels blocked and new outlets have to be made.

TWO FOREIGN COLLEAGUES

called upon me the other day from the *Neue Freie Presse*, which, as everybody knows has the position of *The Times* in Austria. I was most interested in what they had to tell me and perhaps even more in what was left unsaid. They had come over to make arrangements for various special articles and advertisements for their paper. They were particularly anxious to secure information with regard to British Chemical Industry. Their paper has a wide circulation in the new States which have been constituted as a result of the war, and it seemed very indicative to me that with Germany such a near neighbour there should be such a demand for British chemicals as they anticipated. The whole question of trade with Europe becomes more and more acute as time goes on. The superior persons who are set over us in authority, seem to think that the British Empire ought to be not only self-contained but self-sufficient. We are to look to the Colonies and forget all about Europe. Only last week I heard of a business project in Russia which demands for its furtherance tranquillity; now tranquillity is a timid article and easily scared away, and I fully expect that as the result of recent events the deal will be off.

GERMANY'S ECONOMIC POSITION

is discussed in the Annual Report of Mr. J. W. F. Threlwall and Mr. C. J. Kavanagh, Commercial Secretaries respectively at Berlin and Cologne. There are even fewer references to German Chemical Industry than in the last Report, but on the general economic financial conditions in Germany it is most illuminating. The authors warn their readers that "extreme caution must be exercised in expressing any opinion as to Germany's real position at the end of 1922. Inflation dominated every phase of public and private life, and inflation means constant fluctuation." An old point which is constantly raised in discussions in this country is dealt with. We frequently hear of enormous sums of money deposited by Germans in our own or other foreign banks. In Germany the figure usually mentioned is £50,000,000 only, while others outside Germany place it at ten times as much. In the opinion of the writers of the Report it cannot exceed £200,000,000. This does not seem very much to Germany's creditors.

FURTHER TROUBLE IN THE RUHR

has led to the closing of more German dyeworks last week. The Hochst dyeworks and the chemical factory at Weiler-ter-Mer were occupied, but of more importance still at Ludwigshafen the works of the Badische Anilin und Soda Fabrik were seized by the French troops. This move is no doubt made in order to secure reparation dyes due to France and Belgium, but if the precedent of coal is to be followed it does not follow that much in the way of dyestuffs will be very speedily obtained. What effect this will have on dyestuffs due to Britain on reparations account is difficult to see, but fortunately it will not place colour users in this country in any great difficulty.

IN THE MIDST OF SUCH TROUBLE

it is pleasant to record the fusion of the British Chemical Trade Association and the Chemical and Dyestuffs Traders' Association. The new association will take the name of "The British Chemical and Dyestuffs Traders' Association," and the offices in it have been judiciously filled by good men from each of the old bodies. From the inclusion of the word British in the title I take it that some attempt will be made to see that only British firms are admitted to the Association. There will be plenty of work for the Association to do. The business in foreign chemicals and dyestuffs has not been too good lately, and I should not be surprised to find a number of traders resolving very publicly to support British manufacturers, and deal only in British products. Meanwhile the Association's programme for the repeal of the Dyestuffs Act and the Safeguarding of Industries Act hangs fire. If you want to sell British goods it hardly seems worth while to do away with Acts of Parliament which enable the manufacturer to make the goods you want to sell.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

Volume VII (price 7s. 6d. to members) is now ready and an order form with full particulars has been sent to every member of the Society.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL MEETING

CAMBRIDGE. JUNE 20 TO 23, 1923

Accommodation of Members in Colleges. Accommodation will be available for men in various colleges from the afternoon of Wednesday, June 20, to the afternoon of Saturday, June 23. Members who arrive on Wednesday will be charged an inclusive fee of £3, those arriving on Thursday an inclusive fee of £2. These fees include the use of a set of rooms (bedroom and sitting-room), attendance, gratuities to college servants and the following meals: *Wednesday, June* 20.—Tea (if required) and dinner. *Thursday, June* 21.—Breakfast, lunch and dinner. *Friday, June* 22.—Breakfast, lunch and dinner (if required). *Saturday, June* 23.—Breakfast, and lunch (if required). Members will usually take their breakfasts in their rooms. Luncheon and dinner will be served in the halls of colleges. On Thursday and Friday tea will be served at the Vice-Chancellor's reception, and at the Garden Party at Sidney Sussex College respectively. Members who arrive before five o'clock on Wednesday, and who will require tea, are requested to give notice to that effect on a form to be supplied. There will be no extra charge. Members unable to attend the Annual Dinner of the Society on Friday, and desirous of dining in college that evening, may do so without extra charge by giving notice to that effect on the form above referred to. Members who do not make the trip to Ely, and who require luncheon before leaving Cambridge on Saturday, may obtain it in college on that day without extra charge.

It is important to note that alcoholic drinks are not included in the charges specified above, and members requiring such drinks with their meals must sign a chit presented by the waiter at the time of ordering. Payment for such must be made by members at the office of the Society at the Arts School, Bene't Street, on Saturday, before departure. It is the wish of the college authorities that no money shall change hands at table, and it is hoped that members will kindly co-operate in order that this scheme of payment may be a success.

To the list of colleges offering accommodation given on page 491 of the last issue of *Chemistry and Industry*, Corpus Christi is to be added. As previously stated, men requiring accommodation should communicate with Mr. J. E. G. Harris, the University Chemical Laboratory, Downing Street, Cambridge, who will supply any further information and forward a form to be filled up by the member.

Hotel Accommodation. There are still rooms available at The Bull and at The Blue Boar, but the other hotels are more or less full. There is good accommodation to be obtained in boarding houses (college rooms) should the supply of hotel rooms be exhausted.

Guide to Cambridge. A copy of the illustrated Guide to Cambridge will be forwarded to each member who has purchased his ticket as soon as supplies are received from the publishers.

J. P. Longstaff,
General Secretary

THE SOCIETY'S MEDAL

As already announced, the Council of the Society has this year awarded its medal to Dr. Charles Carpenter, C.B.E., in recognition of his distinguished services to chemical industry.

Dr. Carpenter, who became a member of the Society in 1893, is the President of the South Metropolitan Gas Company, having been appointed chairman at the end of 1908, soon after the death of Sir George Livesey. The whole of his business life has been spent in the service of the Company, which he entered as a young man fully appreciating the importance of chemical and physical science to industry. He was soon given an important post on the technical staff of the Company, and on being appointed chief engineer in 1899 he found ample scope for the exercise of his scientific and imaginative temperament in the application of science to gasworks operations. The standard burner for the determination of the illuminating power of towns' gas, and universally known as the No. 2 Metropolitan Argand, was evolved by him, and he further investigated and applied on the large scale the catalytic process of purification of coal gas from sulphur.

In 1914 he became associated with the late Lord Moulton in an endeavour to re-establish the dye industry in England. The supply of high explosives, however, becoming of supreme importance, he was appointed a member of the High Explosives Committee, where he was acknowledged by Lord Moulton to have been one of his most valued colleagues. He was also a member of the Munitions Inventions Department, of the Chemical Inventions Committee, and of the Nitrogen Products Committee.

He was President of the Society during the important stages of the War from 1915 to 1917, during which time, jointly with Dr. Rée of Manchester and Dr. Alexander Scott of London, he was instrumental in forming the Association of British Chemical Manufacturers, of which he became first chairman. He is a member of the Council of the Institution of Civil Engineers and throughout the whole of his professional career has always been an ardent advocate of the closest co-operation between the engineer and chemist.

MEETINGS OF OTHER SOCIETIES

CERAMIC SOCIETY

The spring meeting of the Refractory Materials Section was held at the Town Hall, Bournemouth, on May 3 and 4. There was a full programme of papers to be read, and in addition visits were paid to Messrs. Pike Bros.' clay mines at Wareham, and to two works at Parkstone.

The first paper was on "The Geology of the Bournemouth District," by Mr. H. Dewey, and was followed by a lecture on "The Physical Properties of Clays," by Mr. A. S. E. Ackerman, B.Sc. The latter paper was a somewhat disconnected review of the results obtained by the author during a period of more than five years occupied in investigations on the subject. Some very interesting results emerged from time to time, but they have been published in five separate papers, and could not be dealt with to any advantage in a brief report.

An important paper was contributed by Mr. G. M. Gill on "The Use of Refractory Materials in Gas Works." Mr. Gill discussed many of the aspects of gas-works practice, and pointed out the objects to be aimed at and the most promising methods of attaining those objects under actual working conditions. He had found that a temperature of 1280° C. in the combustion chamber of a retort setting sufficed to carbonise a 10½ cwt. charge of Durham unscreened coal in a 20-ft. retort in 12 hours. At 1320° C. the same charge could be carbonised in 10 hours, and at 1400° C. in 8 hours. Mr. A. H. Middleton's paper on "Silica Brick for Coke Ovens," mentioned a similar experience of a very large increase in the quantity of coal carbonised in coke ovens as the result of a comparatively small increase of temperature. During a visit to America, Mr. Gill found that 20 gas works and coke oven works which he inspected were all using the higher temperatures alluded to above, and carbonising at a much greater speed than is customary in this country. In America all the material used was high percentage silica material. In this country there was a large quantity of clay which could be employed to produce refractory materials possessing the disadvantages neither of fireclay nor of 95 per cent. silica material. This semi-silica or silicious material might even claim to be the happy medium between the two, neither, like fireclay, showing too much after-contraction and too ready a tendency to soften under load, nor, like 95 per cent. silica material, showing too much after-expansion, thus giving rise to the necessity of building in millboard, wooden strips, or of leaving spaces in the setting. There was scope for the production of more material having a silica content varying from, say, 76 to 92 per cent., according to the position in the setting and the purpose for which it was required. The same class of material could be used with great advantage for producer arches and walls, and for the crowns of arches in horizontal retort settings. Quite 75 per cent. of the material required for building modern retort settings should show not more than 1 per cent. maximum expansion or contraction at 1350° to 1400° C. under load, the remaining 25 per cent. being of a quality showing not more than 1 per cent. maximum expansion or contraction at 1280° C. under load. Well-made silica material of good quality should, in Mr. Gill's opinion, be used in all cases for combustion chamber arches. The same material, if carefully made of uniform quality, could be employed to great advantage for building retort settings. There would be required for regenerator chambers a well-made compressed material, without cracks of any sort, and which could be safely used in pieces 1 in. thick, for separating waste gas from secondary air flues. Emphasis was laid on the importance of bricks being burned to a temperature above that at which they will be used in a retort setting, thus obviating to a large extent the after-expansion or after-contraction which was otherwise likely. The question of standardising the dimensions of firebricks and blocks deserved more attention, as expenditure on retort settings was materially increased by the sorting and cutting of bricks, and the alternative of using a thicker joint was very objectionable. It was not unusual to find bricks from the same maker varying ¼ in. in length, breadth or thickness.

Mr. W. C. Hancock read a "Note on the Abrasion of Fireclay Materials." This relates to the simple rubbing away of a surface and not to erosion by impingement of a stream of particles (fuel ash, etc.). A new method was devised for carrying out the tests, and the conclusions reached from the results of many experiments show that :—(1) Fine grained firebricks resist abrasion more than those of coarser grain, and the admixture of grog in increased quantity or increased grain size decreases resistance to abrasion. (2) Abrasion appears to increase at higher temperatures. (3) Hard firing of the bricks tends to decrease abrasion. (4) Increase of abrasion is caused by the addition of load to the wearing surfaces.

The next paper was by Mr. H. S. Houldsworth, M.Sc., and Prof. J. W. Cobb, C.B.E., B.Sc., on "The Behaviour of Clays, Bauxites, etc., on Heating." This is a continuation of a previous investigation, and relates to changes in porosity, density, and refractive index. The authors summarise this work as follows :—"It would seem that definite changes in the kaolinite molecule or crystal unit, as shown by changes in the specific gravity and refractive index, occurred about 450° C., the temperature at which rapid dehydration began, and at 880°, and 950° C., where large shrinkages were observed together with a rapid evolution of heat at the latter temperature. The results indicate the possibility of minor changes at

625°, 680° and 760° C., temperatures at which kaolin exhibited very slight shrinkages. The porosities of the test-pieces increased gradually as the firing temperature of the kaolin was raised up to 1000° C. The true density of the kaolin and presumably the bulk density and the refractive index of the kaolin crystals, had reached their minimum value when dehydration was complete."

In a paper on "Dolomite," Dr. L. M. Parsons said dolomite is usually a pale yellow stony substance, but is sometimes light grey, and is then very difficult to distinguish from limestone. At times it is much darker, and then closely resembles a dark sandstone. It is occasionally tinted bright red by oxide of iron. Sometimes it is very compact, and at other times porous and friable. Dolomite is a double carbonate of calcium and magnesium, and when pure contains 45 per cent. of magnesium carbonate. Dolomite rocks fall into two groups, primary and secondary. Primary dolomites are rare in this country, and of little economic importance. Secondary dolomites were formed by the chemical alteration of rocks originally deposited as ordinary limestones, such alteration being brought about in most cases by the action of water containing magnesium salts in solution.

The last paper was by Mr. A. F. Greaves-Walker (President of the American Ceramic Society) on "The Manufacture of Refractories in America." This comprehensive article deals in a rather summary way with many important points in connexion with the production of refractory materials. As regards fireclay products, brief reference is made to the nature of the components (flint clays and plastic bond clays), and various processes of drying, setting and burning. Other topics of discussion included silica bricks and other products, magnesite and chrome products, plant equipment, and plant organisation. The Schaffer poidometer is now used to measure and weigh automatically mixtures of clays and water between bins and pug mill, the machine having eliminated the pug mill operator. Where wet pans are used, automatic weighing or measuring hoppers are installed in the discharge chute of the bin. The use of variable speed motors and chain drive (instead of belt drive) has added tremendously to plant efficiency as well as conserving floor space. For burning high grade fireclay products large round down-draught kilns are mostly used. One Dressler kiln is in use, and in it is being burned (to cone 12) the most difficult glasshouse shapes with perfect success and practically no loss. The average burning temperatures in different districts range from cone 7 or 8 to cone 14 or 15. Silica products are burned to cone 18 to 20, the burning time being 6 to 12 days. In a commercial burn 80 to 82 per cent. of the quartz is inverted. In conclusion the author described new labour-saving machinery used for making various types of refractory bricks.

IRON AND STEEL INSTITUTE

The meeting held in London, on May 10 and 11, attracted a large number of members, and so full a programme was offered as to suggest that the interest in research work in iron and steel is growing rapidly, and that two days are insufficient for the discussion of so large a number of papers, no less than twenty-four being presented at the meeting, with the resulting unfortunate necessity of curtailing discussions, and even of taking as read communications which would have deserved discussion had time permitted. Fuel questions occupied the attention of members at the first session, much interest being shown in the paper by Messrs. Sutcliffe and Evans on the reactivity of coke, with special reference to the blast furnace. The usual view has been that a good blast-furnace coke should not be too readily soluble in carbon dioxide, as high solubility involves loss of fuel. The authors urge that the blast-furnace should not be regarded as a gas producer, it being easy to generate gas from fuel much more cheaply in a separate apparatus, and that the function of the blast-furnace should be to produce iron of the required quality with a minimum consumption of coke. They concluded, from a comparison with charcoal furnaces, that a coke having a texture approaching that of charcoal, and therefore highly reactive, should give higher efficiency in the blast-furnace, the solubility being an advantage and not a defect. It should be possible to reduce to a startling degree the consumption of coke in the furnace by ensuring that the coke has a certain texture. Such a coke, resembling charcoal, is obtained by briquetting cleaned and finely-ground coal and carbonising slowly. The resulting textures were shown and compared with those of ordinary cokes by means of photo-micrographs. Such a revolutionary proposal did not pass without opposition, and the blast-furnace managers who spoke seemed to doubt the conclusions, and especially contested the application of results obtained from a charcoal furnace to one working with coke on entirely different ores. Much more will be heard of the proposal, the new principles being theoretically sound, though it is difficult to pronounce on their practical value until extensive experiments on a manufacturing scale have been made. This paper was followed by one by Mr. F. Clements, on gas-producer practice in British steel works. This is the third paper of the kind presented by Mr. Clements to the Institute, the former two dealing with blast-furnaces and Siemens furnaces, respectively. The three papers together form a monumental record, of the highest value to practical men and students alike. In each case a full account of experiments made at the Parkgate works is given, followed by a long series of tables giving the dimensions, working records, and full particulars of corresponding plants at the principal works throughout the country, arranged on a comparative plan, and illustrated by sections. It is a testimony to the liberal attitude adopted by British manufacturers of iron and steel that they have so readily consented to furnish Mr. Clements with the particulars of their plant, and the example is one that might well be followed by other branches of chemical industry. Another paper of a technical character was that of Mr. C. A. Ablett on the use of electrical power in iron and steel works, whilst Mr. J. E. Fletcher's account of the grain size and other properties of moulding sands was also of interest from the workshop point of view.

The remaining papers were mainly contributed by laboratory workers, and contained material of great scientific interest, the steel industry probably surpassing all others in the closeness of the relations between science and practice. Prof. Carpenter's communication was a summary of work published by him and by Miss Elam and Mr. G. I. Taylor on the mechanical properties of single crystals of aluminium, and was illustrated by a most striking collection of these remarkable test-pieces. The combined mechanical and X-ray examination of such single crystals is doing more than anything else to throw light on the nature of the processes in the deformation of metals, and practical applications of the discoveries are already in sight. Prof. Arnold gave a summary of his researches on the eutectoids, or "true steels," formed by the alloying of iron with carbon and with such elements as vanadium; researches which established the composition of several of the double carbides present in alloy steels. Two papers dealt with questions affecting the manufacture of open-hearth steel, Mr. T. P. Colclough presenting a review of the reactions in the basic process as depending on the composition of the slag, some useful results being arrived at from the analysis of a considerable number of typical slags and the determination of their relation to the composition of the metal. Some criticism was directed towards the author's explanation of the removal of sulphur, which he attributed entirely to the action of manganese, and opinions on the constitution of the slags were found to differ; but the study undoubtedly clears up some puzzling questions as to the removal of carbon and phosphorus in the process. Messrs. Whiteley and Braithwaite recorded observations on the effect of small quantities of tin, such as enter steel when tinplate scrap is used in its manufacture, on the properties of the product. Even 0·06 per cent. of tin has a harmful effect in rails, and the effect increases with the carbon content, but depends to some extent on the heat treatment.

Prof. Thompson and Mr. A. Goffey presented a note on the changes in iron and steel below 400° C., and by measuring several distinct properties at such temperatures succeeded in confirming the existence of a number of definite changes which are completely reproducible. Changes in the space lattice are out of the question, and for the present the authors are thrown back for an explanation on changes within the atom itself. Much further work will be required to establish a theory of these minute critical points, which have an important bearing on the behaviour of steel on heating to moderate temperatures. Prof. C. H. Desch and Mr. A. T. Roberts contributed an account of the properties of some high-carbon steels containing cementite in the globular form, with special reference to safety-razor blades, showing that the quality of the blades largely depends on that of the cold-rolled strip from which they are made. The cementite has to be brought into the globular condition before hardening, and the quality of the finished blade appears to depend on the uniformity in size and distribution of the globules. Col. N. Belaiew called attention to the properties of damascened steels, in which the whole of the cementite is in the globular form, and which are known to have good cutting qualities. The subject of hardness was treated in two papers, Mr. H. O'Neill considering the relation between the Brinell hardness and the load applied in making the test, arriving by extrapolation at a figure which he calls the "ultimate hardness," which is independent of cold-working; whilst Prof. Edwards and Mr. Austin compared the Brinell hardness with the figures obtained by means of a rebound test. Two papers, which might well have been discussed together had time permitted, dealt with the quantitative interpretation of the tensile test, Mr. J. Stead analysing carefully a series of tests of steel, and plotting the results in such a way as to obtain a straight line as soon as the yield point is passed, whilst Mr. T. F. Russell, by an analysis of similar data and the application of thermodynamical reasoning, attempted to deduce the proportion of vitreous material present in a test piece after elongation, and thence to calculate the probable thickness of the vitreous films between the gliding surfaces. A determination of the change in density of wrought iron by overstrain, by Mr. J. W. Landon, led to surprisingly high values, which call for further investigation. A number of papers remained, discussion on which was impossible, although several were of high interest, and will assuredly be criticised when they become available.

Nothing at recent meetings of the Institute has been more remarkable than the evidence of the value of such purely scientific work as the study of steel by means of X-rays and the examination of single crystals for the practice of metallurgy. Particularly do such researches hold out a prospect of replacing the present empirical methods of determining the mechanical properties of metals by a more logical and simpler process.

An interesting feature of the meeting was the presentation of the Bessemer Medal to the veteran technical journalist and engineer, Dr. W. H. Maw, whose long association with *Engineering* has been the means of rendering most valuable service to the iron and steel industry, as well as to the allied industries.

At the annual dinner, presided over by Mr. F. Samuelson, a large attendance of members listened to hopeful speeches in reference to the revival of industry, the conditions in the manufacture of iron and steel being much better than appeared to be probable last year.

THE FARADAY SOCIETY

Five papers were read at the meeting held on May 14.

(1) "Some Notes on the Etching Properties of the α and β Forms of Tri-Carbide of Iron." By Dr. F. C. Thompson and E. Whitehead. During work on the etching properties of the carbides in alloy steels it was found that a dilute solution of ammonium oxalate did not stain cementite red, whereas a tungsten steel containing a carbide which had the etching characteristics of cementite gave a deep red colour. The authors, therefore, investigated the possibility that a small amount of tungsten might have caused the retention of that form which is normally stable only above 200° C. Of etching reagents tried that which best differentiates between the two forms of carbide is potassium copper cyanide. Confirmation was found of the fact that samples quenched from below 300° C. are self-tempering. (2) "An Example of Polymorphism in an Inter-Metallic Compound." By D. Stockdale. The conclusions arrived at were that there is good evidence for the existence of the compound Cu_2Al and that this compound is capable of existing in two polymorphic forms. (3) "The Elasticity of Organogels of Cellulose Acetate." By Dr. E. W. J. Mardles. The determination of the elasticity of a gel is complicated by the persistence of deformation and optical anisotropy, after removal of stress, so that the elasticity is perfect only for very small stresses applied for a short time. The relation between the modulus of elasticity and concentration for the organogels of cellulose acetate is not expressed by any simple formula, and addition of substances to the gel mainly affects the modulus in proportion to the change in the number of particles which aggregate. (4) "The Vapour Pressures of Concentrated Cane Sugar Solutions." By E. P. Perman and H. L. Saunders. The authors gave an account of experimental work on cane sugar with concentrations ranging from 10 per cent. to saturation, and gave tables showing vapour pressures at various concentrations. (5) "Some Experiments on the Hardness and Spontaneous Annealing of Lead." By A. L. Norbury, M.Sc. The author described a method of making low-load Brinell impressions with a lever-tensile machine, and discussed the effect of cold-hammering on the hardness of lead, the results showing an increase in hardness and in spontaneous annealing.

A BURNING QUESTION AND A BONE'S CONTENTION

By CALORIFER

Prof. Bone is clearly, to use his own term, in an "activated"* condition, absorbing and giving out energy at a great rate. Recently, he delivered a course of Cantor Lectures, at the Royal Society of Arts, on "Australian Brown Coals and Lignites." On May 9 he appeared on the same platform as a modest resurrectionist, to demonstrate developments of the Bone-Court surface-combustion process. In the interval, on April 27, he brought before the Royal Society an account of the refined study he has made of gaseous combustion at high pressures together with Messrs. Newitt and Townend, a continuation of the work begun with the late Mr. W. A. Haward, whose untimely death, through the accident of an explosion, is to be lamented in connexion with the investigation. This work was further discussed by Prof. Bone in a Friday Evening Discourse, at the Royal Institution, on May 11. His appearance in the Press, as a sentimentalist, holding up his hands in pious horror at the percentage of carbonic oxide in coal gas, is also to be reckoned against him.

Apart from the interest attaching to all work on combustion and fuels at the present time, we may rejoice at the fact that the glorious yet greatly neglected art of gas analysis is not only kept alive but is being developed, under Prof. Bone's fostering care, in these inquiries; some day, perhaps, when our students think for themselves and consider what is good for their souls, when our Universities value efficiency and facilitate change of domicile to this end, a Pilgrim's Way will be established to the South Kensington School and the gentle art so faithfully fostered there will be extended over the country—the manner of our present neglect is a disgrace to us, the more so as we are now given over to the internal-combustion engine and the ignorance of engineers of all that pertains to its chemistry.

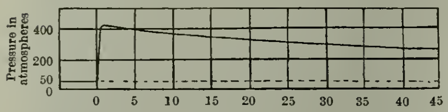
A little surface criticism of our artist's several activities may not be out of place and lead him to consider the validity even of some of his own conclusions. The Royal Institute lecture was disappointing, as it was read and there were no original demonstrations; there was too much personal matter.

Essentially, Prof. Bone's work has involved the comparative study of the combustion of hydrogen and carbonic oxide, whether by oxygen alone or in presence of gaseous diluents. We have long known that the behaviour of carbonic oxide is peculiar and that there is a "lag" in its combustion by air; this is the more surprising as the two gases are isothermic. The lag is not noticeable when oxygen is used alone with either gas. The work derives its value from the exact way in which the pressures developed throughout the explosions have been followed by means of a special Petavel manometer giving an optical trace on a moving photographic film.

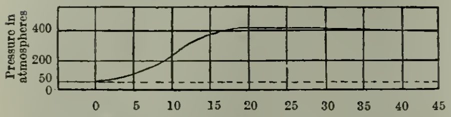
---

* A horrid, un-English word, which a self-respecting Royal Society publication committee should disallow.

Two curves given in the Royal Society Memoir are reproduced to illustrate the character of the results.



Expt. 1.—$2H_2+O_2+4N_2$ Time in 1/100 seconds.



Expt. 2.—$2CO+O_2+4N_2$ Time in 1/100 seconds.

The pressure rises, in the hydrogen-air mixture, almost instantaneously to a maximum and then declines in a regular, rather rapid manner. In the carbonic-oxide-air mixture, the pressure rises but slowly to about the maximum attained in the hydrogen mixture and then remains steady during a surprisingly long interval, when it gradually falls. If either carbonic oxide or oxygen or even argon be substituted for nitrogen (no other gas can replace it), the behaviour of the mixture is practically that of the hydrogen mixture.

It is clear, therefore, that nitrogen has a specific influence in retarding the combustion of carbonic oxide. What can this be ?

Prof. Bone and his co-workers seem to go out of their way to seek an explanation of the "anomaly." They suggest three possibilities. First, the resolution of the nitrogen molecule into its atoms. Secondly, a mere alteration of the electronic configuration of the molecule, such as has been suggested as possible by Langmuir : a sort of stretched spring hypothesis. Thirdly, that the nitrogen molecule is able to absorb and transfer into vibrational energy within itself a part of the total energy liberated when the carbonic oxide and oxygen interact.

Each of the three kinds of change postulated as possible in the nitrogen molecule, being the effect of heat, should be equally promoted in the isothermic process of combustion with hydrogen ; moreover, both oxygen and carbonic oxide should be thermally lowered in stability when present in excess in place of nitrogen and should have some if not an equal effect : argon alone might be expected to be without appreciable influence.

Peculiar to nitrogen is the power of being oxidised to nitric oxide. At the Royal Institution Prof. Bone both drew attention to the formation of "nitric acid" in the explosion of carbonic oxide and demonstrated its production. It seems but necessary to assume that nitric oxide is formed reversibly to account for the observed lag in the rise as well as in the fall of pressure ; in hydrogen, such action would occur, if at all, to so slight an extent or would be so rapidly reversible that the effect would not be obvious.

It is strange that Prof. Bone makes no attempt to consider the general course of change in gases ; he has gone out of his way in a previous paper to assume that either oxygen atoms or "activated" molecules of hydrone (how these may be made active is in no way clear) are required to oxidise carbon monoxide. It seems impossible for chemists to arrive at any rational conception of chemical change or to view the phenomena in any consistent comprehensive manner : the human mechanism apparently is so built that logical imagination comes rarely within its orbit. Prof. Bone will pardon these remarks, I trust, as he has lamented the fact that his explanation did not provoke discussion.

Turning to the Royal Society of Arts demonstration, the invention of a means of burning a gaseous mixture at the surface of a porous slab by Prof. Bone and Mr. McCourt will be in the memory of all who witnessed their remarkable demonstration, a dozen or more years ago : some of us thought we were on the eve of a new fuel era. In practice, the method was but partially successful in this country, as back-firing easily set in. Recently, Prof. Bone tells us, this difficulty has been overcome by Mr. Cox, who has devised means of properly grading the particles of which the slabs are composed. Various forms of the burner were shown and their use successfully demonstrated. These included a gas cooking stove which can be used in grilling steaks etc. ; numbers of these stoves are already in action in Messrs. Lyons' restaurants and elsewhere.

Prof. Bone originally claimed an efficiency of 93 per cent. for the boiler constructed on his principle. Now that the difficulty of back-firing is overcome, it is to be hoped that an exhaustive trial of the principle will be made without loss of time. It is proposed to call the new appliance a radiophragm. This is too awful a word for common use.

At the meeting, in proposing the vote of thanks, Professor Armstrong spoke of the possible near advent of a gas millennium and of electricity being used in the household merely in assisting the burning of gas—by blowing the bellows required to produce the necessary pressure of air.

Now that gas is coming so much to the fore, it will be necessary to establish a public gas conscience and that we become judges of gas. There has been absurd talk in the Press of late of displacing the carbonic oxide in coal gas by hydrogen by the time-honoured steam process. Even if this were an economically sound proposition, the change would be in the wrong direction and the gas less suitable for ordinary use than it is now. The inventor seems to have realised this, as methane is spoken of as a better substitute—but it is yet to be shown that the conversion into methane is practicable and then that it is economically possible.

PHOSPHATE DEPOSITS IN MOROCCO

According to a report furnished by H.M. Consul at Casablanca, Morocco is said to possess deposits of phosphates rivalling in extent those of Florida and in content those of any other country in the Eastern hemisphere. The Oued Zem-El-Bouroudj beds, 150 kilometres south of Casablanca, cover an area of 400,000 acres and are composed of a fine sand containing 73 to 78 per cent. of tricalcium phosphate. Deposits in other districts contain from 68 to 72 per cent. of phosphate. Thus, the Moroccan phosphates should assuredly find a ready market, provided production and transport expenses are kept low enough. At present exploitation is a State monopoly, the actual enterprise being conducted under a board of management; 7 square kilometres of deposit are being worked, and the phosphates extracted are dried in a machine which has a daily capacity of 30 tons. Production has increased from 8,230 tons in 1921 to 85,583 tons in 1922. Further development depends on the provision of adequate transport and port facilities, as the sale price at present does not cover the cost of extraction, but it is hoped to increase the output by 200,000 tons annually and to reach a total of 1,100,000 tons by 1927. The superphosphate factory now in erection at Casablanca will be completed this year and should produce annually 24,000 tons of superphosphates, which will be largely exported, as there is as yet but little local demand. Some indication of the potential market may be gathered from the fact that in 1913 the European consumption totalled 4,413,000 tons, of which North Africa supplied 2,345,000 tons, the United States 1,618,000 tons, and France and Belgium 450,000 tons. In addition to the anticipated production of over 1,000,000 tons from Moroccan deposits in 1928, Algeria and Tunisia should be producing from 3½ to 4 million tons at about the same date.

Dr. A. H. Hull, of the Research Laboratory of the General Electric Co., N.Y., has been awarded the Howard N. Potts gold medal of the Franklin Institute for his studies on the crystal structure of common elements by means of X-rays.

FORTHCOMING EVENTS

May 28.	The Faraday Society, at the Institution of Electrical Engineers, Victoria Embankment, W.C. 2, at 3 p.m. and 8 p.m. Discussion on "The Physical Chemistry of the Photographic Process." Between the afternoon and evening sessions dinner will be held at the Hotel Cecil at 6.45 p.m.
May 30.	Royal Microscopical Society, 20, Hanover Square, W. 1, at 6.30 p.m. "On the Microscopical Examination of China Clay," by J. M. Coon. "The Microscopical Investigation of Sands for Various Industrial Purposes," by H. B. Milner.
May 31.	Institution of Electrical Engineers, Annual General Meeting, Savoy Place, W.C. 2, at 6 p.m.
May 31.	The Royal Institution of Great Britain, at 3 p.m. "The Nature of Enzyme Action," by Sir W. M. Bayliss, LL.D., D.Sc. Also on June 7.
June 1.	The Royal Institution of Great Britain, at 9 p.m. "The Radiation of Light," by Prof. H. A. Lorentz.
June 1.	The Royal Society of Arts, at 4.30 p.m. (Indian Section.) "The Indian Section of the British Empire Exhibition, 1924," by A. Kendall, I.C.S. retd.

THE ELECTRONIC THEORY OF VALENCY

A General Discussion on the above subject is being arranged by the Faraday Society, to be held at Cambridge on July 13 and 14. Prof. G. N. Lewis will open the proceedings on the afternoon of July 13 (Friday) with an Introductory Address, and he will probably be followed by Mr. R. H. Fowler, who will contribute a paper intended to open discussion on the physical and inorganic side of the subject. Among those expected to speak are Sir J. J. Thomson, who will be in the chair, Sir E. Rutherford, Sir W. Bragg and Prof. W. L. Bragg. The Saturday morning session will be devoted chiefly to applications of the theory in organic chemistry. Sir R. Robertson, president of the Society, will preside, and opening papers will be given by Prof. T. M. Lowry and Dr. N. V. Sidgwick. Among those expected to speak are Prof. W. A. Noyes, Sir W. J. Pope, Prof. A. Lapworth, Prof. I. M. Heilbron, Dr. W. H. Mills, Prof. J. F. Thorpe and Prof. R. Robinson. On the Friday evening a complimentary dinner will be given to Profs. Lewis and Noyes and other guests at Trinity Hall. Arrangements are being made to accommodate those attending the meeting in one or other of the Colleges, and it will be possible to include a limited number of non-members of the Society. Particulars may be had from the Secretary of the Faraday Society, 10, Essex Street, London, W.C. 2, to whom applications should be made at once.

CORRESPONDENCE

THE TAXATION OF MOTOR FUEL

Sir,—The recent correspondence from Professor Procter and Dr. Ormandy raises two distinct issues. One concerns the comparative calorific values of motor fuels, the other deals with methods of levying the Road Tax. The two questions only overlap in deciding how to tax the fuel, should that course be adopted.

The first of these questions is liable to considerable misconception. There are three chief types of fuel, known commercially as petrol, benzol and alcohol; and the B.Th.U. per gallon of these may very roughly be stated in the proportion of 14 for petrol, 15 for benzol and 9 for alcohol. These figures are, of course, a measure of the relative amount of work obtainable from each fuel, but that is not all.

In the first place, for complete combustion, the air to fuel ratios (by weight) are roughly as 15 to 13 to 9. This means that very much more alcohol may be used in one explosion than benzol or petrol. Secondly, the relative latent heats are (again roughly) in the ratios 12 to 16 to 40. The larger the latent heat the lower the temperature of the mixture and consequently the bigger the charge. These two factors enable one to get as much as 20 per cent. more power output from alcohol than from benzol and petrol, but at a correspondingly increased consumption. There are numerous other considerations of efficiency which have their smaller effects on the relative merits of the fuels and it is sufficiently accurate to state that, when developing the same power output, the alcohol fuels will entail a consumption, say, 30 per cent. greater than benzol and 20 per cent. greater than petrol.

Whether the fuel of the future will be of the alcohol and benzol type which can be used at very high compression without combustion knock, and consequently with superior efficiency, is open to question. At the moment there are indications of a tendency in quite the opposite direction, that is to the use of heavy paraffin fuels which cannot be employed except at relatively low compression and with hot running, but which are economical on account of their cheapness. In any case, the motor engineer is finding that the bark of the much discussed "pinking" is worse than its bite.

I hesitate to tackle the second problem (that of the Road Tax) as so much has already been said about the matter by all manner of experts. If the tax is to come again on to the fuel there will certainly be waste enough without the introduction of a tax graded according to the physical properties of the fuel.

But to the humble mind it seems quite reasonable that the present system could be modified to make the tax equitable and just to all parties. First let the experts decide the relative road-usage of the various types of private and commercial vehicles when in fullest use throughout the whole year, and the value to the community of this usage. Then let them fix a scale of charges for each type when in fullest use.

Let those who wish to, take out a full licence for the year, but for the week-end motorist and the less successful transport contractor let us have a short time licence at a not too exorbitant figure. Why not a daily licence at about ½ per cent. of the annual cost? The police would be able to control evasions as easily as they can under the present system.

By this means the injustice of the contractor being forced to pay for a yearly licence, when he can only find work for his lorries on a hundred days or so, and of the private motorist having to take out his licence for the winter months, when he scarcely uses the car at all, will be avoided, and a state of affairs which is a serious setback to the whole motor industry will be abolished.—I am, Sir, etc., P. J. Bate

Sanderstead
May 14, 1923

CALCIUM LACTATE

Sir,—Concerning Mr. J. C. Stead's remarks on the price of calcium lactate, in your issue of May 4, I should like to point out that whey is by no means the only source of this material. If he will refer to Mr. Claflin's paper on the Avery process, in the *Journal* for 1897, p. 516, he will find that by inoculation of sterilised saccharine matter, such as liquid glucose, with lactic acid bacilli (*B. acidi lactis*, *B. lactis ærogenes*, *etc.*) in the presence of chalk and nitrogenous matter, very high yields of calcium lactate are obtained. The process can be extremely cheap, and is used—in America, at any rate—to produce the bulk of the lactic acid (by decomposition of the calcium lactate) used in the dyeing, tanning and other industries.

The uses of calcium lactate in comparison with those of lactic acid are small, being chiefly pharmaceutical, and hence the price is to some extent a fancy one.—I am, Sir, etc.,

LABORATORY ORGANISATION

Sir,—It may seem churlish on our part to cavil at anything in your excellent and sympathetic review of our book on *Laboratory Organisation*, but in justice to ourselves we should like to point out that the gas-fired combustion furnace referred to stands under the main ventilating shaft of the laboratory, which does not come into the field of view of the photo, and a hood for it is therefore unnecessary.—We are, Sir, etc.,

Seymour Pile
Reginald G. Johnston

Queen's College, Birmingham
May 15, 1923

Sir,—I am glad to note Mr. Seymour Pile's explanation of the apparent discrepancy between precept and practice in the matter of the ventilation of the combustion furnace referred to in my review. I, however, having no personal acquaintance with the structure of the laboratory was obliged to gain my impression from the plate and I think this impression, which Mr. Seymour Pile now shows to be an erroneous one due to the limitations of the photograph, will be shared by most readers of the volume.—I am, Sir, etc.,

T. Callan

Crumpsall, Manchester
May 15, 1923

PERSONALIA

It is announced that £12,000 has been given anonymously to Armstrong College, Newcastle-on-Tyne, to provide more facilities for research in pure and applied science.

In the entrance hall of the chemistry laboratories of University College, London, Viscount Chelmsford recently unveiled a tablet to commemorate the donations of Sir Ralph Forster towards the erection and equipment of the new chemistry laboratories.

* * *

The death is reported, at the age of 77, of Dr. Charles Liven, late of Aberdeen University.

With regret we announce the death on May 16 of Mrs. Mond, the widow of the late Dr. Ludwig Mond, F.R.S. Under the provisions of the late Dr. Mond's will, a bequest will now be paid of £50,000 to the Royal Society, which is to utilise the income to endow research in natural science and particularly in chemistry and physics, to publish the Society's reports and papers, and to prepare and publish catalogues and indexes of scientific literature. A similar sum is bequeathed to the University of Heidelberg to endow research in natural science, and £20,000 for pensions or assistance to workmen of Messrs. Brunner, Mond and Co.

The death is announced of Monsieur F. Devignes, a member of the International Petroleum Commission.

THE CHEMICAL ENGINEERING GROUP
THE INSTITUTION OF CHEMICAL ENGINEERS

We are requested to announce that the offices of the Chemical Engineering Group have been removed from 24, Buckingham Street, Strand, W.C. 2, to Abbey House, Room 308, Victoria Street, S.W. 1, to which address all communications to the Group should in future be sent.

It is also announced that the offices of the Institution of Chemical Engineers have been removed from 166, Piccadilly, W. 1, to Abbey House, Rooms 306 and 307, at the same address as that of the Chemical Engineering Group.

NEWS AND NOTES

UNITED STATES

Research on Soap

It is announced that the Palmolive Co., of Milwaukee, has established a Fellowship of $2000 per annum for the study of the fundamental principles connected with the detergent action of soap. The Fellow, who must possess the equivalent of a Master's degree, will be allowed to carry out his research at any Institution in the United States that is properly equipped for the purpose.

Sulphur and Pyrites in 1921

The output of sulphur in the United States in 1921 was 1,879,150 long tons, valued at $17,000,000, the largest output recorded, being 52,565 t. larger than that of 1918, a former record year. Roughly only half of the production was shipped, however, and stocks of sulphur held at the mines consequently reached large figures, 2,000,000 t. being in stock at the end of the year. Exports totalled 285,762 t., chiefly to Canada, France, Australia, Germany, England and Sweden. The domestic production of pyrites increased by 49 per cent. in quantity and 55 per cent. in value to 157,118 t., valued at $711,432. Sulphur was produced chiefly in Texas, and pyrites was produced chiefly by California (63 per cent. of the total), New York, and Wisconsin. Imports of pyrites were 216,229 t. (332,606 t. in 1920) and were the smallest recorded since 1896.

FRANCE

Industrial Notes

The sequestrated factories belonging to the German firm of Baeyer and Co. at Flers, near Lille, have been put up for sale in six lots, but no buyers came forward.

The Minister of Public Works has invited metallurgists to stock one-third of the coke that they are now receiving from the Ruhr until a total of 250,000 metric tons, *i.e.*, enough to supply French metallurgists for fifteen days, has been accumulated.

Wool Disinfection

The Central Committee for Wool has announced that in its opinion the question of the disinfection of wool is not within the competence of the International Labour Bureau and that it should not be put on the agenda of the meeting in 1923. If, however, the subject is still discussed, the Council of the Central Committee for Wool considers that the cost of disinfecting infected wool should be paid by the country of origin and not by the importers.

Output of Potash in Alsace

The output of potash in Alsace reached the record amount of 1,326,727 tons in 1922, as compared with 903,134 t. in 1921, 1,222,370 t. in 1920, and 592,365 t. in 1919. At present not only are chloride manufacturers working at full capacity, and producing over 250,000 t.

of potassium chloride per annum, but the Société Commerciale des Potasses d'Alsace is producing a large amount of potassium sulphate.—(*U.S. Comm. Rep.*, *Apr.* 9, 1923.)

GENERAL

Synthetic Ammonia in Spain

It is reported that Monsieur G. Claude is establishing a factory in Spain for a Spanish Syndicate to manufacture synthetic ammonia by his process. The plant is designed to utilise from 3000 to 4000 cb. m. of hydrogen per day, the output of the adjacent electrolytic soda plant of the Electro Quimica de Felix Co.

New Process for Manufacturing Superphosphates

It is reported from Spain that a process has been evolved for the manufacture of superphosphates containing 20 to 30 per cent. of water-soluble phosphoric acid from low-grade phosphate deposits. Experiments hitherto made at Caceres are to be repeated on an industrial scale, and, if successful, should make it possible to utilise large deposits of low-grade phosphates in the central regions of Spain.—(*U.S. Comm. Rep.*, *Apr.* 2, 1923.)

European Beet Crop, 1922-23

Dr. Prinsen Geerligs, in a cable dated February 16, 1923, reports that the 1922-23 beet-sugar crop in Europe amounted to 4,550,000 metric tons, raw value, a decrease of 180,000 tons from the previous estimate (4,730,000 tons). The total production is distributed as follows :—Germany, 1,500,000 t.; Czechoslovakia, 720,000 t.; Poland, 330,000 t.; Russia, 200,000 t.; Holland, 270,000 t.; Belgium, 280,000 t.; France, 475,000 t.; Italy, 290,000 t.; Spain, 140,000 t.; other European countries, 345,000 t. (*Ind. Tr. J.*, *Apr.* 19, 1923.)

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Formaldehyde and Rochelle Salt

In a written answer to Capt. W. Benn, Lieut.-Col. Buckley stated that application had been received for the exclusion of Rochelle salt and formaldehyde, respectively, from the schedule under Part 2 of the Safeguarding of Industries Act. The cases would be brought before the Referee in due course.—(May 11.)

Preservatives in Foodstuffs

Mr. N. Chamberlain, answering Mr. A. Bennett, said that he was considering the composition of the proposed committee to enquire into the use of preservative colouring matter in foods.—(May 16.)

Dangerous Drugs and Poisons (Amendment) Bill

The amendments added to this Bill in the House of Lords were considered and passed on May 16.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for May* 17)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Belgium	Rubber goods	627
,,	Metal ingots	628
,,	Pharmaceutical specialities	630
British India	Gutta-percha cable (tender)	*
Bulgaria	Metallurgical coke (tender)	10681/F.E./T.C.
Germany	Metals, plate-glass, chemicals, iron, oils	632
Canada	Canada plates, sheets, tinplate	625
Colombia	Hardware, hollow-ware, chemicals, drugs	656
Egypt	Glassware, paint, oil	652
,,	Chemicals, dyes, varnish, copper circles	653
Norway	Sugar	640
,,	Photographic materials	641
South Africa	Red oxide paint (tender No. 442)	11264/E.D./C.C./2
Sweden	Asbestos, optical goods	647
Switzerland	Copper, spelter, zinc, nickel	648
,,	Scientific, optical and surgical instruments	651

* Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.

TARIFF CUSTOMS EXCISE

Denmark.—The issue for May 17 contains a copy of the amended "Luxury Tax" Law, which affects, among other goods, glassware, rubber, artificial silk, machinery, iron and steel, metals, sensitised photographic paper, hides and skins.

Italy.—The duty on imported sugar has been withdrawn.

Newfoundland.—The duty on sugar has been reduced.

Sarawak.—Restrictions have been placed on exports of rubber.

Switzerland.—The period during which the importation of goods may be restricted has been extended to March 31, 1924.

REVIEWS

An Introduction to the Chemistry of Plant Products. *Vol. II.* Metabolic Processes. *By* Paul Haas, D.Sc., Ph.D., *and* T. G. Hill, A.R.C.S., F.L.S. *Pp. viii*+140. *London: Longmans, Green and Co.*, 1922. *Price 7s. 6d. net.*

This book contains much valuable information on the synthesis of fats, carbohydrates and proteins, and on the chemistry of respiration and growth. It is concise in its presentation, and provides not only a digest of the extensive relevant literature which is dealt with faithfully and historically, but it is also commendable for much valuable comment essential to a true estimation of the present state of knowledge on many debatable points in plant chemistry. The book is remarkable for the lucidity of explanation with which each chapter is opened. This is conspicuously the case in the presentation of the subject matter on the synthesis of proteins and on respiration, regarding which the writer knows no statement both so brief and yet clear. There is perhaps no other book of the dimensions of the present volume to which the student of organic chemistry can turn with such satisfaction for an epitome of modern views on the chemistry of plant metabolism. Its authors are to be heartily congratulated on its production. John McLean Thompson

Vital Factors of Foods, Vitamins and Nutrition. *By* Carleton Ellis, S.B., F.C.S., *and* Dr. Annie Louise Macleod. *Pp. ix* + 391. *London: Chapman and Hall, Ltd.*, 1923. *Price 25s.*

There are two classes into which the majority of books on vitamins can broadly be classified; those which deal with the subject in an elementary manner for popular reading, and those which are compiled as scientific monographs. Both types, if well written, have their particular value, but it is not easy to classify the volume under review. It is quite unsuitable, and was probably never intended for the general public, whereas, on the other hand, it lacks most of the desirable features of a scientific treatise. In its exhaustive treatment of the voluminous literature on the vitamins which has grown up during the last ten years it resembles a monograph, but there is an almost entire absence of any critical examination of this material, without which such a work becomes merely a lengthy and extended bibliography. To some extent this may be due to the authors not being, so far as the reviewer is aware, actually engaged in research in this field, but, on the other hand, when such is the case, the work should gain by the impartial handling of the subject.

As a mere compilation of the work that has been published on vitamins the book is good, and few references of importance appear to have been omitted. The main criticism is, as we have remarked above, the almost complete lack of judgment in presenting the material. To give only one example, we find on pages 182 and 184 references to the work of Uhlmann on the pharmacological action of one of the vitamins. The conclusions of this worker are given without any comment, in spite of the fact that Uhlmann was working with a commercial product, which from its method of preparation must have contained many substances other than vitamin B showing physiological activity, amongst them probably choline, and that, therefore, the interpretation of his experimental observations is, to say the least, very much under suspicion. On the whole the book is well produced. There are, however, numerous evidences of imperfect proof correction, whilst in the copy submitted for review the photographs facing page 289 would be unintelligible were it not that the subscription informs us that they represent rats. There is a note of appropriateness in the first sentence of a paragraph from one of Joseph Conrad's books with which the authors introduce their book: "All one's work might have been better done." J. C. Drummond

Practical Plant Biology. *By* Prof. H. H. Dixon, F.R.S. *Pp. xi* + 291. *London: Longmans, Green and Co.*, 1922. *Price 6s.*

This is a book of considerable interest to a much wider field of students than that for which it was designed. It professes to present an introductory course in botany for medical and other science students. This profession is admirably fulfilled. The book will also commend itself readily to many teachers by its novel presentation of many familiar objects. It contains much interesting information on plant chemistry which is seldom detailed with simplicity and directness in such books. In this it provides a happy offset to the more rigidly systematic and morphological statements which have characterised so many modern botanical treatises.

The book may be viewed as a welcome representation of biological phenomena, and its author is to be congratulated upon it. Much of the illustration has been prepared personally by the author; and though it cannot be viewed as of a high standard, it possesses the merit of being well selected.

John McLean Thompson

Die Beziehungen zwischen den Fettkonstanten. *By* Jakob Lund. *Pp.* 75. *Berlin: Julius Springer*, 1922.

This pamphlet consists of a reprint from the *Zeitschrift für Untersuchung der Nahrungs und Genussmittel sowie der Gebrauchsgegenstände* (Vol. 44, Part 3), an abstract of which has already been given in this Journal (1922, 944a). In the present reprint the analytical data have been amplified, and it will doubtless be found useful for purposes of reference.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£24 per ton.
Acid Hydrochloric	4s.-5s. per carboy d/d.
Acid Nitric 80° Tw.	£24 10s. per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton.
Arsenic (White)	£70-£75 per ton.
Bleaching Powder	Spot £11 7s. 6d. d/d. Contract £10 7s. 6d. d/d.
Bisulphite of Lime	£7 per ton, packages extra.
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£27 per ton
Potash Caustic	£35-£36 per ton
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b.
Soda Caustic 76%	£20-£21 per ton.
Soda Crystals	£5 10s. per ton.
Sod. Acetate 97/98%	£26 per ton.
Sod. Bicarbonate	£10 10s. per ton.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	2⅞d.-3d. per lb.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, conc.	£16 per ton carr. paid.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£26-£28 per ton according to quantity.
Carbon Black	1s. 5½d. per lb. ex wharf. Still very scarce.
Chromium Oxide	1s. 5d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb. Firmer on advance in price of Rape Seed Oil.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood-distillation products. Wood tar has advanced in price.

Acetate of Lime—	
Brown	£10 15s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 10s. per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 9d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£6 per ton d/d.
Brown Sugar of Lead	£43 5s. per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 5d. per lb. Little movement in the market.
Crude 60's	3s. 6d.-3s. 9d. per gall. Market weaker.
Acid Cresylic—97/99	2s. 2d.-2s. 5d. per gall. Market quiet.
Pale 95%	2s.-2s. 4d. per gall. Not much demand.
Dark	1s. 10d.-2s. 0½d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	9½d.-10d. per gall. Not much demand.
Unstrained	9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8½d. per gall. Business slack, abundant supplies.
Pure	2s.-2s. 3d. per gall.
Toluole—90%	1s. 9d.-2s. per gall.
Pure	2s.-2s. 6d. per gall. Not much inquiry.
Xylol	3s.-4s. per gall. according to quality.
Creosote—	
Cresylic 20/24%	11½d.-1s. per gall. Not much business.
Middle Oil Heavy Standard Specification	8½d.-9½d. per gall; Market steady.
Naphtha—	
Crude	9d.-9¼d. per gall.
Solvent 90/160	1s. 7d.-1s. 9d. per gall. Fewer inquiries.
Solvent 90/190	1s. 5d.-1s. 8d. per gall. Market steady.
Naphthalene Crude—	
Drained Creosote Salts	£7-£8 per ton.
Whizzed or hot pressed	£11 10s.-£14 per ton. Plenty of enquiries.
Naphthalene—	
Crystals	£18 per ton.
Flaked	£16 per ton.
Pitch, medium soft	No business for this season. Prices for Autumn delivery 130s.-135s. per ton.
Pyridine—90/140	11s.-12s. per gall. More enquiry.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

A slight falling off of business in dyestuffs is fully accounted for by the Whitsun holidays. Orders for forward delivery have been coming in fairly well and still further improvement is anticipated. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
p-Dichlorbenzol	£70 per ton.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	4s. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works. Good demand.
Nitronaphthalene	1s. per lb. d/d.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market generally is quiet, the forward position being uncertain in view of the Continent being unable to offer supplies except at values which are considerably higher than present spot prices. In several cases holders are willing to accept low prices in order to realise part of their stocks, but the general tendency is towards higher prices in the near future if the position in Germany remains unchanged.

Acid, Acetic 80%	£50 per ton.
Acid, Acetyl Salicylic	3s. 2d.-3s. 3d. per lb. Smaller demand and market weaker.
Acid, Benzoic	2s. 6d. per lb. Still very scarce at this figure.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton. Prices reduced by £5 per ton.
Acid, Citric	1s. 9d. per lb., less 5%. Dearer; demand active; higher prices expected.
Acid, Gallic	3s. per lb. Steady demand.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb.
Acid, Salicylic	2s. 3d. per lb. still quoted. For firm orders in quantity 2s. 1d. would be accepted.
Acid, Tannic	3s. 3d. per lb. for good light quality.
Acid, Tartaric	1s. 4d.-1s. 4½d. Demand good.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d. per lb. Very firmly held.
Amidopyrin	13s. 6d. per lb. Unchanged. Stocks are small and any heavy demand would result in higher prices.
Ammon. Benzoate	3s. 6d. per lb.
Ammon. Carbonate B.P.	£37 10s. per ton.
Atropine Sulphate	12s. per oz. neglected.
Barbitone	Quoted up to 20s. per lb. Much firmer owing to lack of supplies in quantity.
Benzonaphthol	4s. 6d. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Bromides	Better inquiry. Prices steady. Potass. 8d., Sod. 9d., Ammon. 10d. per lb.
Calcium Lactate	2s. 9d. per lb. for best makes.
Chloral Hydrate	4s. per lb. Price well maintained. More inquiry.
Chloroform	2s. 3d. per lb. for cwt. lots, ton lots being quoted down to 2s. per lb.
Creosote Carbonate	10s. per lb., with little enquiry.
Formaldehyde 40%	£90 per ton. Very firm.
Guiacol Carbonate	8s. 6d. per lb.
Hexamine	4s. per lb. would now be accepted for quantity.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Market good with considerable inquiry.
Magnesium Carbonate—	
Light Commercial	£38 per ton nett.
Magnesium Oxide—	
Light Commercial	£85 per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Menthol	35s. per lb. spot.
Methyl Salicylate	2s. 6d. per lb. for carboys.
Methyl Sulphonal	15s. per lb. Slightly higher in value.
Mercurials	Unchanged. Market quiet.
Paraformaldehyde	4s.
Paraldehyde	1s. 7d. per lb. Very steady. Forward prices show a higher tendency for best makes.
Phenacetin	6s. 6d. per lb. spot value.
Phenazone	7s. 6d. per lb. Very firm.

Phenolphthalein	5s. 6d. per lb. In short supply. Larger quantities appear to be unobtainable even at this figure.
Potass. Bitartrate—99/100% (Cream of Tartar)	98s. per cwt., less 2½%. Firmer.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. Demand still continues good.
Potass. Permanganate	10d. per lb. for large quantities. Forward market very much firmer.
Resorcin	6s. per lb.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Salol	2s. 9d. per lb.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 6d. per lb. Still in short supply, fresh stocks being quickly absorbed.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality.
Sod. Hyposulphite—Photographic	£15-£17 per ton, according to quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d. per cwt. Fairly good demand.
Sod. Salicylate	In good supply. Values unaltered, being 2s. 9d. per lb. for Powder, 2s. 11d. per lb. for Crystal. Some prominent makers have reduced their rates to meet competition.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. per ton, according to quantity for home trade, 1-cwt. packages included.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.
Thymol	In view of fairly large stocks being held keen competition still exists to obtain orders. The value of genuine good White Crystal remains at 17s. per lb.

PERFUMERY CHEMICALS

Petitgrain Oil	8s. 3d. ,, ,,	

TRADE NOTE

Reparation Dyestuffs

The Board of Trade draws attention to the fact that, under the Reparation Clauses of the Peace Treaty, requisitions are made periodically for the delivery of certain German dyestuffs on reparation account. Information on the requirements of colour users for dyestuffs which cannot be obtained from British manufacturers is collected by the Colour Users' Association and furnished periodically to the Board of Trade. In order that this information may be as complete as possible the Board would be glad if all users—whether members of the Association or not—would furnish particulars of their estimated requirements for German dyestuffs, say once every three months, to the Secretary, Colour Users' Association, Cromwell Buildings, Blackfriars Street, Manchester.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES London, June 1, 1923 No. 22

EDITORIAL

THE latest Bulletin of the Société de Chimie Industrielle contains an interesting editorial on the subject of the Union Internationale de la Chimie and its approaching meeting at Cambridge. In an article published last December in the *Journal of Industrial and Engineering Chemistry*, Prof. W. A. Noyes, of the University of Illinois, asked for the admission of Germany to the Union Internationale. This request is discussed in the editorial we have referred to, and special mention is made of a suggestion by Prof. Noyes that the reason why Germany and Austria have not been admitted is that the Allies consider themselves on a higher plane than the Central Powers. The French attitude on this point is very frankly displayed by the Bulletin, and with due recognition of his friendliness and high-mindedness they regard Prof. Noyes as misinformed as to the French mentality. "*La réserve que nous manifestons vis-à-vis des Allemands n'a jamais eu pour mobile cette présomption, qui serait pour le moins bien ridicule, de nous considérer sur un plan plus élevé que quiconque. Nous ne pensons pas être le jouet de la vanité, ni d'un sentimentalisme exagéré, encore moins d'un esprit nationaliste qui aveuglerait notre bon sens.*" It is pointed out that the manifesto of some of the German savants has neither been disavowed by its authors nor regretted by the others, and that some such step is desirable in the interest of pleasant relations. We do not venture to express any opinion on such a question of delicacy.

* * *

We have no claim or wish to speak on behalf of British chemists on such a topic as the policy of the Union, nor any intention of so posing. But the point is one of considerable importance, and if the question is to be canvassed at Cambridge it is no use shirking the discussion either from a desire to escape responsibility or from a reluctance to be frank. There is no reason why such a question should not be considered primarily from the point of view of the Union Internationale. If any nation desires that its chemists shall meet in friendly fashion those of other countries for the better advancement of the science, the questions which naturally first arise are,—will any degree of friendliness actually exist ? and, is the proposal made with the idea of helping on the activities of the Union Internationale ? The meetings of the Union held so far have been particularly cordial and harmonious. It is undoubted that, other conditions being equal, the more countries that are represented the better ; but if Germany is admitted, will an element of discord spring up which will reduce the usefulness of the conferences ? This is not an easy question to answer. Hitherto it has never been necessary to consider whether at lunch Monsieur A or Signor B or Professor C would feel any awkwardness in sitting next door to each other. Whether a German manufacturer, whose works on the Rhine are now guarded or occupied by French troops cares to enjoy a *tête-à-tête* with a French manufacturer whose works, say in Lille or Chauny, were destroyed by German troops, we have no means of judging ; but in a period when continuity is so important for its progress the Union Internationale perhaps cannot afford to be split up by two inharmonious elements, each striving to secure the adhesion of a considerable mass of more or less neutral sentiment.

* * *

In our columns we remember to have read a few reviews of German books on chemistry, in which the reviewer has suggested that the recent work of British chemists on the particular subject has been ignored. Whether it is a mere accident or not, we are not sufficiently informed on the matter to hold an opinion ; but if by any chance it is considered by some few writers to be patriotic when a convenient opportunity occurs for a German to ignore or treat lightly the work of the British and other foreign chemists in order that the reader of the book may infer that German chemistry alone is worth troubling about, the policy would appear to us to be one which is singularly injudicious and unfortunate. We have had sharp disagreements at times with the French, and we do not suppose that the British are unduly popular in France at the present moment; but whatever may be our political differences, we know that the French chemists have worked hard during the last three years to make the Union Internationale a success, with perfect sincerity and goodwill. They have not been inspired by the need to call our attention to the importance of French chemists and the superiority of French methods over every other. This sort of spirit has characterised French scientific men for a long period. Was not a famous memoir of Davy crowned by the Académie des Sciences in Paris, in 1807, when a fierce war divided France from England? It may well be that the point of view we have indicated in these notes is merely evidence of our ignorance; those who control the destinies of the Union Internationale need neither our advice nor our support. We merely indicate some of the considerations which affect a decision at the moment and express the hope so pleasantly phrased by our contemporary a year ago, "*qu'aucun malentendu ne devait diviser ceux qui ont pour mission commune d'ameliorer le sort des hommes.*" In time a better spirit will prevail in Europe; there ought to be no jealousies, no resentments, no bitter memories; few of us are entirely free from blame. But whether an attempt by any third party at such a time as this to promote friendly conferences between the French and German chemists will advance or retard an era of cordiality must be a matter of conjecture. On the other hand, no one will dispute that when the French and German chemists have mitigated some of their present feelings of hostility, and when both are willing to work together to increase the usefulness of the Union, not to justify the claim to be on any particular plane of intellectual or other activity, then the time will have appeared for a new and greater importance of the Union Internationale in the domain of chemistry. The publication of the French point of view requires some comment, and we put forward these observations quite modestly, believing that a little preliminary thought on the matter will show how difficult are the questions involved. More than a score of nations are represented in the Union; many different points of view may be urged. We, in this country, are only one factor, but our columns are open for the expression of opinion on all matters of interest to chemists, and our considerable circulation outside the United Kingdom will give us special facilities for learning the views of many chemists in many lands. It is possible that when these are available Prof. Noyes may consider the advisability of postponing any formal proposition.

CHEMISTRY—THE KEY TO INTERNATIONAL RELATIONS

By H. E. HOWE

(*Continued*)

Japan has for years enjoyed a monopoly of camphor which has been a distinct advantage to that country. Camphor is used extensively in the arts, notably for the production of celluloid, motion-picture films and the like, and in international relations cannot be ignored. This advantage to Japan has been partly lost of late through the demonstration that camphor trees can be grown in other countries, through the remarkable synthesis of camphor in the laboratory, and through research which has been successful in producing certain substitutes for camphor. It is said that for some industrial purposes none of these materials give quite the same results as the native camphor, but there is no reason to doubt that the cause for any difference will be found.

Like soda ash, sulphur is basic in the chemical industry, particularly in those phases essential for the sinews of war. Sulphur is the raw material for making sulphuric acid. The prosperity of a nation in peace and its strength in war can almost be measured by its production and consumption of sulphuric acid, and it has even been said that the civilisation of a country can be so estimated. The Sicilian corner in sulphur, managed by an English syndicate, has been entirely broken through the success of chemical engineering in America. Sulphur formerly came almost entirely from Sicily, but this sulphur was seldom pure and was unsatisfactory for some uses. It was known that a thousand feet below the surface in Louisiana and Texas deposits of sulphur were to be found. Several attempts to reach them had only resulted in a loss of life and investment. Then came a chemical engineer, who believed that he could successfully work within those narrow temperature limits where sulphur changes from an easy running liquid to a viscous, sticky mass. His plan was to force superheated water and steam down to the deposit so that the sulphur would melt and under pressure flow to the surface. When the experimental plant was ready and the first hot water turned into the pipes it was but a few moments until a stream of liquid sulphur more than 99 per cent. pure appeared at the surface. Presently the operation was stopped and it was weeks before it could be made to function again. However, it had been demonstrated that the plan was sound, and the engineer persisted. Today America has the commanding position with respect to sulphur. Indeed, but for an arrangement with the English syndicate regarding price, the entire Sicilian industry would have been destroyed and the people left without a means for earning their livelihood. It is interesting to note that when the report of how pure sulphur was being pumped from the ground in America was first made to the English sulphur syndicate, the man who dared pass along such an exaggerated Yankee story was dismissed.

Canada enjoys a certain power through her great resources of nickel and asbestos. She has also relied upon her wood pulp, a product of chemical industry, to back her claims in international councils.

Few nations have been so favoured as has Germany through the control of the natural resources made valuable by chemistry. This is particularly true of the great potash beds which, however, were not discovered until long after the deposits had been worked for ordinary salt. With the utilisation of rock salt deposits in various localities, a time came when the price of salt fell, and the Stassfurt works ceased to yield their former large revenue to the Prussian Government. With a view to making them more valuable, it was decided to sink the shaft further, in the hope that rock salt might be discovered. At a depth of 1800 feet a stratum of rock salt was found, but in reaching it the shaft passed through a heavy deposit of refuse salts which were considered worthless. Chemical analysis showed these salts to consist largely of magnesium-potassium chloride and potassium chloride. The Dutch scholar Van't Hoff demonstrated that these materials could be separated by crystallisation, and to-day these refuse salts are the world's chief source of supply of potashes and potassium salts.

An effort is being made in the United States as a result of war activity to break this potash monopoly. Whilst a part of the deposit is no longer German property, the deposit as a whole might at any time give those nations controlling it a commanding position. The natural lakes of Nebraska, the alunite ores of Utah, and the greensands of New Jersey are sources of potash that at present prices cannot compete with very low mining and purification costs abroad. The fact that the greensands of New Jersey yield as a by-product the material for sand lime brick in an area where construction creates a demand for this building material may well prove a saving factor in that instance. The greatest deposits now being worked in America are those at Searles Lake, California, where research similar to that conducted by Van't Hoff on German deposits, but of a different and higher order of complexity, has shown that the mixed deposit of that lake can be commercially separated. Potash of high purity is being produced, with quantities of borax among the by-products. We are also told that Texas may at any time be able to announce extensive potash deposits. Italy is supporting research in the hope of recovering potash from leucite.

Another weapon which Germany has not hesitated to use has been her manufactured chemicals, especially her dyes. Years ago she began with cunning to make a world monopoly to be utilised for the furtherance of her ambition. The use of patents, particularly product patents, extensive propaganda and advertising, and even the adoption of specifications for colours, strengthened her hold. There is reason to believe that the requirement that dyes used in dyeing our military uniforms must withstand washing in a bleach solution dates back to the time when the only colours that would withstand this test were made in Germany. The effort to hold world textile trade by limiting the export of dyes to this country early in the war will be remembered, and a careful watch of the literature of Germany to-day and of the addresses presented before various conferences indicates that the Germany of the present puts her greatest hope for rebuilding her world influence upon the potentialities of her chemistry.

The changes in world relations due to new explosives will be obvious. Many world policies were changed with the completion of the Panama Canal, which would have been impossible but for the work of medicine and sanitation combined with chemical explosives. TNT., our most recent example, was responsible for the rapid reduction of those Belgian cities which were protected with concrete fortifications. Concrete, itself made by a chemical process, might not have been so easily crumbled but for the research on toluol. Toluol is used as a basic material in certain types of dyes. When it is nitrated, two mono-nitro-toluols are formed simultaneously. One of these mono-nitro-toluols was desired for dyes ; for the other there was no known use. Research was therefore undertaken with two objects in view : first, to produce a larger proportion of the mono-nitro-toluol which was wanted for dyes ; and second, to discover a use for the other variety. Little progress was made, and suddenly the problem disappeared from the scientific literature. After Liége it became known that upon further nitration it had been found that tri-nitro-toluol could be formed from that mono-nitro variety undesirable for dye uses. Consequently efforts were bent toward increasing rather than decreasing the toluol which could be transformed into this high explosive.

Aircraft problems of to-day are chemical problems in large measure. These include materials of construction, not only metals which must have a minimum of weight with a maximum of strength, but laminated propellers protected so that their dimensions and balance may not be disturbed, and a variety of fabrics as well. The varnishes, adhesives, and the many other items which taken together give us aircraft, depend upon either chemical manufacture or chemical control. The materials of operation, the lubricants, the fuels, which in themselves are difficult problems, also belong to chemistry. Materials for buoyancy, the balloon fabrics which are required to remain flexible and yet impermeable to gases, present a real chemical problem. Helium appears to be a natural American monopoly, and through chemical engineering we have learned how to separate it from the other gases with which it is found, purify it, store it, and use it in our balloons. In few instances has science had a better opportunity to dictate international relations than in the development of aircraft.

Fats and oils of vegetable origin have taken and hold a real place in affairs. They have even brought about strange tariff problems. Such oils have always been of commercial importance, but with the advent of hydrogenation it lies within the power of any country possessing the chemical knowledge and skill and the ability to grow such crops as peanut, cotton and other oil-bearing seeds to prevent fat starvation among its people. Hydrogenation of oils is another example of the efficiency of catalysts. The difference between certain liquid fats or oils and the hard fats like lard is, chemically speaking, an atom or two of hydrogen in each molecule. To add this hydrogen was not so simple, but eventually it was found that the heated oil passing concurrently to a stream of hydrogen in the presence of nickel, the catalyst, took up this hydrogen in the proper form and upon cooling a hard fat resulted. Sixty million pounds of such fat were made by a single plant in the United States in 1922. It has meant an increase in the value of many oils which have thus been elevated from technical to food uses, leaving a place in turn for cheaper oils which, after hydrogenation, have become suited to be their successors.

No one doubts that power in the future will rest very largely with that nation which controls such sources of energy as petroleum or the materials from which future fuels may be made. The utilisation of the constituents of petroleum depends upon chemistry. Scientists have for some time been conducting research on possible substitutes for petroleum, and in Germany $5,000,000 has already been invested in research designed to produce a method for making liquid fuel from coal by hydrogenation and chlorination. Intensive work is under way in the United States on improved methods for cracking off those parts of petroleum which are suitable for internal combustion motors, and at last the automotive engineer is directing his attention to more efficient forms of motors with which available stocks and possible future supplies of liquid fuel may be profitably used.

All over the world people have been looking to alcohol as a source of energy. The problems are economic rather than technical, and depend to a large extent on our ability to find cheap annual crops sufficiently rich in starch or the type of cellulose that can be converted into fermentable sugars to produce cheap alcohol. Coal may become essential to motor-driven vehicles, for the production of gas, benzol by-products and electricity, and the opinion has been ventured that hydro-electric power may be called upon to furnish the energy for electric motor vehicles. The desire to use high compression engines has introduced the great problem of so-called anti-knock compounds, and here again the chemist is working hand-in-hand with the engineer.

The internal combustion motor must also be considered in the light of what our future source of food may be. Many expect the tropics eventually to feed the world. The motor may be looked upon as a means by which man may overcome the tropics, so that this whole problem of fuel and food which lies at the very basis of all civilisation may be directly concerned in tropical agriculture.

In the War of the Revolution opposing forces are said to have held their fire till they could see the white of the combatants' eyes. By the time of the Civil War the range had lengthened, but firing was often point-blank, and in the Spanish-American War 60,000 yards was the maximum graduation required on the range finders. Now it is the horizon which must be within the measurement of the larger range finders, and we have gone on to sound ranging, observation balloons and data secured by the airplane. In all this distance work optical instruments are essential, and for their manufacture ordinary glass will not do.

Not so long ago a single nation controlled the production of the finer grades of optical glass, and was successful in discouraging its attempted manufacture elsewhere. The shortage of glass early in the world war was a really serious affair, and alarming consequences might have resulted. However, optical glass is a chemical product, and American chemists overcame the handicap. Glass makers of long experience marvel that these scientifically trained men became familiar with and solved production problems so quickly. Early in the work chemists who had specialised in the chemistry of the silicates were able to evolve a diagram from which they could predict the physical characteristics of glass from its predetermined chemical composition. When this work had been demonstrated as successful, there was no longer any difficulty in obtaining the co-operation of experienced makers, with the result that no finer glass has ever been produced than that made in the United States.

From the earliest times disease has been an overwhelming factor in international relations. It is now thought that the Aztecs were conquered not by the Europeans but by the smallpox which the Europeans brought with them. Greece and Rome fell before malaria, and in our own day the Panama Canal became possible only when disease was conquered. The white man can never realise on the wealth of the tropics until ways are found for protecting him from numerous tropical fevers and diseases. Perhaps in no war were such great pains taken to protect and keep normal the health of the forces both in the field and at home as was the case in the world war. Scientific reports now state that, recognising what a mighty host medicine is, our former enemies proposed to secure and hold for themselves the key to tropical Africa by means of a certain remedy. This chemical compound has given encouraging results with tropical diseases, particularly fevers, and it was proposed to make this remedy available to the people of other nations only on terms which required the restoration of lost colonies. Modern sanitation and preventive medicine make many an outpost tenable which otherwise could not be held, and constantly extend to the ends of the earth the influence of those nations which have seen to it that their scientific development has not been allowed to lag.

Chemical warfare, a development forced upon the world through the acts of a single nation, is capable of becoming the most feared, humane, efficient, and financially economical military weapon. Despite treaties and prejudices, it remains one of the few outstanding factors of to-day in its influence upon world relations. It places a premium upon intelligence, for in chemical warfare it is the intelligent who are best able to defend themselves and attack the enemy. It is in a large measure a leveller of nations, since a small country efficient in chemical warfare is more than a match for a great country unprepared.

The products of peace-time research are knowledge, skill, and technical perfection, which present no storage problems and find their healthful exercise, not in playing at war nor in its foment, but in the chemical industry. The relation of research to sanitation, the destruction of insects, rodents and other pests, and the importance of developing a real centre for toxicological information are obvious. Many opponents of chemical warfare are to be found; but, the world over, it is recognised that the nation which knows most of the fundamental science, chemistry, upon which defensive and offensive chemical warfare rests, may some day dictate international policies.

Electrometallurgical products have not been without a part in these international relations. Without European magnesite for the linings of steel furnaces, it might have been difficult to produce ferrous alloys to the exacting specifications of the war period. But we learned how to use American linings, and, thanks to success in the production of artificial graphite, there was no difficulty in providing huge electrodes for steel furnaces with a uniform quality and the dependable characteristics which were essential. Ferrochromium, necessary in armour-plate production, is also used in making projectiles. Ferrosilicon is an essential for basic open-hearth steel production, which makes up the greatest part of our steel output. Without ferrosilicon we could make no sound steel castings nor shrapnel. Without ferrotungsten and the other tool-steel alloys, our munition production would have been in a sad plight, for it is with such steel that a lathe which has been using high carbon steel can be made to nearly triple its output. Calcium carbide, from which acetylene is produced, became important in the last war in an unexpected way, for this acetylene became the source of solvents which heretofore had only been made by the distillation of certain hardwoods. To-day the electric furnace is being turned to many other production problems, including phosphoric acid from the phosphate ores and a process for sodium carbonate which may eventually displace those now so well established.

A discussion of this sort would be far from complete without reference to rubber, used in insulation, which is so necessary for modern methods of communication and in many parts of modern transportation systems, as well as for weather, water, and wind-proofing. For balloon fabrics, gas-masks, and scores of other items it is essential. Whilst there is probably no country in which the manufacture of rubber products has been developed more extensively than in the United States, the centre of crude rubber production has shifted from the western hemisphere to the eastern, and American manufacturers are now not only without sources of crude rubber controlled by them, but have no facilities for training men to perform the special task of managing and developing rubber plantations. Certainly no industry can allow this condition to continue, for rubber as an item of world importance can no longer be ignored. The synthesis of artificial rubber must also be developed. One of the latest contributions of chemistry to the rubber industry has been the development of organic accelerators. With these organic compounds vulcanisation can be carried on in something like 20 per cent. of the time formerly required, so that a given vulcanisisng department can now support the requirements of a plant at least twice the size formerly possible.

In view of the fundamental research now in progress upon the structure of the atom and the molecule, it is not unreasonable to believe that the chemist will have obtained the skill which will enable him to produce uniformly and in quantity the types of molecules specified. When the physician understands what is required to combat a new form of disease or to overcome an old one, he may, and before long, specify to the research chemist the type of molecule which will be efficient in overcoming it. This does not seem so visionary when we remember that we already have available many wonderful medicines and remedies, the counterpart of which is not found in Nature, and that we have indeed set up, as in the use of mercurial and arsenic compounds, a molecule that will conquer the organism invading the body without disturbing that extremely delicate balance which characterises the human being.

The contributions of science, and particularly of chemistry, have been the means by which we have made our world grow smaller. Through modern methods of communication and transportation we have become near neighbours to nations which formerly were so far away as to seem to be on another star. In the short space of a hundred years developments in electricity and a little knowledge of the radioactivity of matter have produced wireless telegraphy and telephony. With an increase in our knowledge of how to make energy available, and how to apply it efficiently, has come a speeding up of all kinds of transportation. Pure and applied science has gone a long way towards eliminating time and distance in international affairs, and in consequence the peoples of this world must learn to live closer together. Perhaps this also may be accomplished through science and scientific men. Their labours make life easier, more profitable, and longer. These fruits cannot be fully enjoyed in the midst of turmoil.

All this is but a part of the story—just a few illustrations of what chemistry does to justify the designation of a " key to international relations." The safety of a country's world position and its influence in international relations may indeed be measured by the degree to which fundamental research is fostered, science applied in the solution of industrial problems, and by the extent to which its people generally appreciate the significance of chemistry.

In most respects the signs of the times are encouraging. While at the moment our facilities for trained men exceed the demand for them, yet support is being given pure research. Our university and college equipment is being greatly improved, so that North America may assume world leadership in fundamental research. Industries are also turning to science. More than forty trade associations in the United States include research in their programme of activity. Military establishments realise that no treaties forbid the acquirement of knowledge, which is the really vital factor in defence. For the sake of a peaceful future, it behoves all peaceful nations to make an ally of chemistry and of all science. Perhaps science can succeed where other means have failed in stabilising world affairs.

History is replete with examples of nations which have tried all manner of physical means to exclude the rest of the world and grew strong within their own boundaries. Superior intelligence has usually been the overpowering force. The Great Wall of China, which held for centuries, is but a line on the landscape to the airplane developed by science. Blockades by land and sea have been made ineffective by science within. Natural barriers, such as mountain ranges and the sea, are overcome, while the power inherent in natural resources is minimised by the synthesis of the laboratory.

More and more the key to international relations and national prosperity becomes superior knowledge to be obtained only through the encouragement of invention and the support of fundamental research in the sciences. As ever, " knowledge is power," and science ever calls upon those who appreciate her to undertake the accomplishment of the impossible.

THE ELECTRON THEORY OF VALENCY APPLIED TO CO-ORDINATION COMPOUNDS

By C. H. SPIERS, M.A., B.Sc.

The present writer has been engaged in a study of co-ordination compounds for a considerable time, and some months back he arrived at a theory of their structure which appears to be the same as that advanced by Professor Lowry in *Chemistry and Industry*, March 29, 1923, p. 316. That is to say, he came to the conclusion that the formation of complex ions was the expression of the tendency of the central atom to increase the number of electrons in its outer layer to the number in the outer layer of the inert gas immediately following. It achieves this by sharing one pair of electrons with :—(1) Groups or atoms which are one electron short of completion—*e.g.*, Cl, CN, NO_3, NO_2, $\frac{1}{2}$ (SO_4), $\frac{1}{2}$ (OOC.COO), etc., thereby gaining one electron for each group or atom held. (2) Molecules which have a separate existence—*e.g.*, NH_3, H_2O, CO, NO, etc., thereby gaining two electrons for each molecule held.

Thus, in $K_2[PtCl_6]$, the platinum atom with 24 electrons in its outer layer, gains two electrons from two potassium atoms and six electrons from six chlorine atoms, by sharing a pair of electrons with each. The platinum atom thus completes its shell to 32. In $[Co(NH_3)_6]Cl_3$, the cobalt atom, with 9 electrons in its outer layer, loses three electrons to three chlorine atoms, and acquires 12 electrons by sharing one pair of electrons with each of six ammonia molecules. It thus completes its shell to 18. This is Lowry's view, but it is somewhat different from that of Langmuir (*J. Am. Chem. Soc.*, 1919, **41**, 868.)

This simple theory does not, however, account for all the facts satisfactorily, and the writer therefore did not desire to publish his views until he had made a further study of the problem, and had made some attempt to overcome the various difficulties.

Several points in Professor Lowry's article may require comment. If the equation expressing the reducing action of $K_4[Co(CN)_6]$ is written ionically thus,

$$4K^+ + \left[Co(CN)_6\right]^{----} + H^+ + Cl^- =$$

$$4K^+ + \left[Co(CN)_6\right]^{---} + Cl^- + H$$

it will be seen that the potassium plays no part—it is not reasonable to say " the surplus atom of potassium in potassium cobaltocyanide therefore behaves almost as if it were in the metallic state, and is almost ready to decompose water like metallic potassium, in the effort to get rid of an unwanted electron." The reducing action is due to the complex anion. The formula suggested for potassium ferrioxalate is not altogether satisfactory, since it does not express the different behaviour of the iron and potassium with regard to ionisation.

It is necessary to decide whether to build the theory upon complex ions which exist in solution, or upon those which exist in the solid state. Werner, in his classical work, deals with co-ordinatively saturated complexes, without considering the conditions under which they exist. In the solid state we have $\left[Ni(NH_3)_6\right]^{++}$, $\left[Cu(NH_3)_6\right]^{++}$, and $\left[Zn(NH_3)_6\right]^{++}$, in which, on the present theory, the central atoms acquire outer layers of 20 (10—2+12), 21 (11—2+12), and 22 (12—2+12) electrons, respectively. They all readily lose ammonia. Ammoniacal nickel solutions contain mainly $\left[Ni(NH_3)_4\right]^{++}$ and $\left[Ni(NH_3)_5\right]^{++}$, although we must presume $\left[Ni(NH_3)_6\right]^{++}$ to be also present, since its salts can be crystallised from solutions containing excess of ammonia. Ammoniacal copper and zinc solutions contain only the tetrammine ion, and the salts of the hexammine ion cannot be crystallised from solution. On the whole it seems reasonable to base a theory on complex ions which are known to exist in solution. The existence of ions, such as the above, which contain an excess of electrons, may be explained by the stabilising influence of the solid state (*cf.* dynamic isomers). It is, of course, of great importance that Werner's theories should be tested by the investigation of crystals of complex salts by X-rays. Wyckoff has already obtained some confirmatory evidence.

As Lowry shows, certain complex ions exhibit a shortage of electrons and, in some cases, these are remarkably stable. It was felt that this stability was inconsistent with such a deficiency. It is now suggested that the innermost pair of electrons, both of the central atom and of the co-ordinated atoms or groups, may be utilised to help the completion of the shell of the central atom (*cf.* Eastman, *J. Am. Chem. Soc.*, 1922, **44**, 438). This hypothesis reduces the number of incomplete shells to a very small number. In general those complex ions whose shells are completed with the aid of these innermost electrons are less stable than those completed without, and those completed with the aid of one of the inner electrons are not so stable as those completed with two. There are no nickel salts of the type, $K_2Ni(X)_6$ corresponding to the salts, $K_2Pt(X)_6$, because nickel does not give Ni^{++++}. We should expect nickel to give $K_3Ni(CN)_5$(18) instead of $K_2Ni(CN)_4$, (16 or extended 18), but apparently complexes containing the unsymmetrical arrangements of 5 and 7, are seldom formed (*cf.*, however, complex halogen salts). When the inner electrons of the central atom are used in assisting the completion of its outer layer, the positive charge of its kernel is increased. This will help to stabilise the complexion.

The assumption, that an atom completes its shell to that of the inert gas immediately following, is not sufficient. It is necessary to assume that, under certain circumstances, an atom will complete its shell to a higher or a lower stable number. Thus, titanium (2, 8, 8, 4) in H_2TiO_3 probably completes its outer layer to 8 instead of 18 (*cf.* H_2CO_3). Uranium (2, 8, 8, 18, 18, 6), in $\left[\begin{matrix}O_2\\UF_5\end{matrix}\right]K_3$, probably achieves an 18 instead of a 32. Copper and silver form compounds $\left[\begin{matrix}I_2\\Cu(S_2O_3)_4\end{matrix}\right](NH_4)_9$ and $\left[\begin{matrix}I_2\\Ag(S_2O_3)_4\end{matrix}\right](NH_4)_9$, in which the central atom completes to 32 instead of 18. {11 (Cu)+9(NH_4)+2 (I_2)+8 (S_2O_3)+2 (inner)=32.}

According to the present theory, the ammonia in an ammine has a definite link with the central atom. If this is so, it should be possible to resolve an ammine containing an odd number of molecules of a tertiary amine, $NR_1R_2R_3$. Another suggested test of the theory is pointed out below. The writer hopes shortly to investigate these points experimentally.

Cyanides.—In the table below, 32 complex cyanides of 20 metals are set out. All of them exist in solution. Twelve achieve the complete layer, three are one electron short, eleven are two short, two are three short and three are four short, while one has an electron in excess. The fourth column contains the number of electrons in the outer shell of the central atom, assuming that one or both of the inner electrons are utilised. Under these conditions 26 cyanides achieve a complete shell. The utilisation of one electron is not satisfactory, since it leaves a single electron near the kernel. Thus, the ions, $\left[Fe(CN)_6\right]^{---}$ and $\left[W(CN)_8\right]^{---}$ (17 or extended 18, and 31 or extended 32) readily pick up an electron giving $\left[Fe(CN)_6\right]^{----}$ and $\left[W(CN)_8\right]^{----}$ (18 and 32). The ion, $\left[Mn(CN)_6\right]^{----}$ (17 or extended 18), by gaining one electron, would form $\left[Mn(CN)_6\right]^{-----}$. This is not possible, since Mn^+ does not exist. Hence it loses an electron giving $\left[Mn(CN)_6\right]^{---}$ (16 or extended 18). $\left[Cr(CN)_6\right]^{---}$ (15 or extended 17) does not pass into $\left[Cr(CN)_6\right]^{----}$ (16 or extended 18) owing to the instability of Cr^{++}. The cyanide ions completed with the aid of two electrons do not usually change by acquiring electrons, which alters the valency of the central atom. They sometimes attract another cyanide ion, thereby gaining two electrons. The five incomplete ions, except chromium, very readily undergo change.

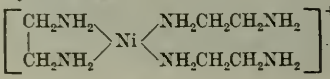
TABLE I

Element		Complex salt		No. of electrons in outer layer on simple hypothesis		No. of electrons in outer layer utilising inner electron
Vanadium (5)	..	$K_3V(CN)_6$	..	14	..	16
Chromium (6)	..	$K_3Cr(CN)_6$*	..	15	..	17
		$K_4Cr(CN)_6$	..	16	..	18
Manganese (7)	..	$K_3Mn(CN)_6$*	..	16	..	18
		$K_4Mn(CN)_6$	..	17	..	18
Iron (8)	..	$K_3Fe(CN)_6$	..	17	..	18
		$K_4Fe(CN)_6$*	..	18	..	18
Cobalt (9)	..	$K_3Co(CN)_6$*	..	18	..	18
		$K_4Co(CN)_6$	..	19	..	19
Nickel (10)	..	$K_2Ni(CN)_4$	..	16	..	18
Copper (11)	..	$K_2Cu(CN)_3$	..	16	..	18
		$K_3Cu(CN)_4$	..	18	..	18
Zinc (12)	..	$NaZn(CN)_3$	..	16	..	18
		$K_2Zn(CN)_4$	..	18	..	18
Molybdenum (6)	..	$K_4Mo(CN)_8$	..	18	..	18
Ruthenium (8)	..	$K_4Ru(CN)_6$	..	18	..	18
Rhodium (9)	..	$K_3Rh(CN)_6$	..	18	..	18
Palladium (10)	..	$K_2Pd(CN)_4$	..	16	..	18
Silver (11)	..	$KAg(CN)_2$	..	14	..	16
		$K_2Ag(CN)_3$*	..	16	..	18
Cadmium (12)	..	$NaCd(CN)_3$	..	16	..	18
		$K_2Cd(CN)_4$*	..	18	..	18
Tungsten (20)	..	$K_3W(CN)_8$	..	31	..	32
		$K_4W(CN)_8$*	..	32	..	32
Osmium (22)	..	$K_4Os(CN)_6$	..	32	..	32
Iridium (23)	..	$K_3Ir(CN)_6$	..	32	..	32
Platinum (24)	..	$KPt(CN)_4$	..	29	..	31
		$K_2Pt(CN)_4$*	..	30	..	32
Gold (25)	..	$KAu(CN)_2$	..	28	..	30
		$KAu(CN)_4$	..	30	..	32
Mercury (26)	..	$KHg(CN)_3$	..	30	..	32
		$K_2Hg(CN)_4$	..	32	..	32

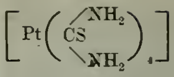
The number after the name of the element denotes the number of electrons in its outer layer. Where an element gives more than one complex, the stabler is marked by an asterisk. It is not always possible to decide this point satisfactorily.

Complexes Containing Ammonia and Nitrogen Bases

Table II. contains 17 complex ions which exist in solution in pure water. Nine have ordinary complete shells, six have complete "extended" shells, and two, silver and chromium, incomplete "extended" shells. Here, again, chromium gives a remarkably stable complex. Although nickel does not form a stable ion $\left[Ni(NH_3)_6\right]^{++}$, it nevertheless gives stable ions $\left[NiEn_3\right]^{++}$ and $\left[NiPn_3\right]^{++}$, whose salts can be crystallised from hot water. These salts have not been resolved into optical antipodes, though the corresponding salts of some other metals have been resolved. It is suggested that two of the diacid base molecules may be held by one nitrogen atom only. The co-ordination number of the nickel would then be four as in the cyanide. The ion $\left[NiEn_3\right]^{++}$ may be written



$$\left[\begin{matrix}CH_2NH_2 \\ | \\ CH_2NH_2\end{matrix}{>}Ni{<}\begin{matrix}NH_2CH_2CH_2NH_2 \\ \\ NH_2CH_2CH_2NH_2\end{matrix}\right]^{++}.$$



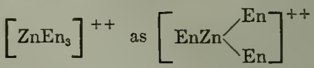
In $\left[Pt\left(CS{<}\begin{matrix}NH_2 \\ NH_2\end{matrix}\right)_4\right]X_2$, we have one molecule of a diamide occupying one co-ordination position instead of two. There are also cases where dibasic acid residues occupy only one co-ordination position—*e.g.*,

$$\left[Co\begin{matrix}CO_3 \\ (NH_3)_5\end{matrix}\right]X \text{ and } \left[Co{\diagup}\begin{matrix}OOC.COO \\ (NH_3)_5\end{matrix}\right]X.$$

In these latter, the cobalt atom gives up one electron to the halogen atom and one to the unattached oxygen atom. If a residue such as OOC.COO is held thus, we might expect a compound

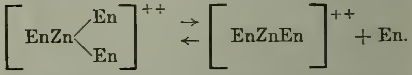
$$\left[Co\begin{matrix}OOC.CHR\ COO \\ (NH_3)_5\end{matrix}\right]X$$

to be capable of resolution. It would, therefore, be of interest to investigate a compound of this type. Perhaps we may also write



$$\left[ZnEn_3\right]^{++} \text{ as } \left[EnZn{<}\begin{matrix}En \\ En\end{matrix}\right]^{++}$$

This is weakly alkaline in aqueous solution doubtless owing to the change,

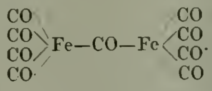


$$\left[EnZn{<}\begin{matrix}En \\ En\end{matrix}\right]^{++} \rightleftarrows \left[EnZnEn\right]^{++} + En.$$

Ruthenium forms compounds in which a molecule of NO shares a pair of electrons with the central atom and contributes two to its shell. This also occurs in such compounds as

$$\left[Fe\begin{matrix}NO \\ (CN)_5\end{matrix}\right]Na_2. \text{ (extended 18).}$$

Carbon monoxide is similarly held in the carbonyls. It should be pointed out that Mond and Wallace, (*T.* 1922, 121, 29) ascribe to molybdenum carbonyl the formula $Mo_5(CO)_{26}$, but such a formula is not probable from the point of view of the present theory. We can write $Fe_2(CO)_9$ as



This would account for its decomposition into $Fe(CO)_5$ and CO and Fe, on being heated to 100° C. and into $Fe(CO)_5$ and $Fe(CO)_4$ on being heated to 95° C. in solution. There are also other types of substances containing CO—*e.g.*,

$$\left[Fe\begin{matrix}CO \\ (CN)_5\end{matrix}\right]K_3.$$

Osmium forms a complex in which two atoms of oxygen occupy two co-ordination positions. They each contribute two electrons to the shell of the central atom. The modes in which this may occur are discussed below.

The readiness with which ammoniacal silver solutions are reduced can be accounted for on the present theory. $\left[Ag(NH_3)_2\right]^+$ has only 16 electrons even using the two inner electrons of the silver atom. It is therefore very unstable and tries to pick up electrons, if possible, from OH ions, for example. This occurs very readily in the presence of an oxidisable substance. Thus :—

$$2\left[Ag(NH_3)_2\right]^+ + 2(OH)^- = 2\left[Ag(NH_3)_2\right] + H_2O + O.$$

The complex, having taken up one electron, becomes electrically neutral, and therefore decomposes into silver and ammonia. A similar explanation accounts for the ready reduction to cuprous oxide of the complex copper anions in, say, Fehling's solution.

TABLE II

Element	Complex salt	No. of electrons in outer layer on simple hypothesis	No. of electrons in outer layer utilising two inner electrons
Chromium (6) ..	$[Cr(NH_3)_6]X_3$	.. 15	.. 17
Iron (8) ..	$[Fe(Dipy)_3]X_2$*	.. 18	.. 18

	$[Pt(NH_3)_6]X_4$	.. 32	.. 23

Dipy= *aa′* dipyridyl.

Oxyacids

Langmuir has dealt satisfactorily with many oxyacids. However, he meets with difficulties in the case of such compounds as the manganates. According to the usual theory, in the oxyacids, oxygen is held to the central atom in one of two modes, viz. :—

(1) By sharing one pair of electrons with it, as in H_2SO_4.

(2) By sharing two pairs of electrons with it, as in HNO_3.

In all cases the central atom completes its shell to 8. In the series commencing with potassium we should expect to find a tendency to complete the shell to 18, as in the cases of the complex cyanides and ammines. It is reasonable to suppose that an element, such as titanium, which has but four electrons towards its 18, may not be able to acquire enough electrons to complete its shell. We can therefore suppose that H_2TiO_3 has a structure similar to that of H_2CO_3—*i.e.*, the titanium atom achieves an 8 layer. Vanadium, as we have seen, achieves a layer of 16 in its complex cyanide, $K_3V(CN)_6$. In the case of H_3VO_4 we can choose between a structure analogous to that of H_3PO_4 (8 layer) and a structure in which the oxygen atoms share two pairs of electrons with the vanadium atom, which thus acquires a shell of 18 (with the help of the two inner electrons of the vanadium atom). The acid HVO_3, which forms colourless ions, can only be represented on an 8 basis.

It seems necessary to assume structures, for the oxyacids of the elements from vanadium, different from those of the elements of the previous series because (*a*) colour begins to manifest itself in the third series with the vanadium oxyacids. The titanate ion (8 shell) is colourless. The chemistry of the vanadate ions is very complicated. It appears that there are colourless and coloured ions. Probably in the colourless ions, we may assume that the vanadium atom completes its shell to 8 in a manner comparable with the elements of the first two series, while in the coloured ions it completes its shell to 18. In the succeeding elements, which give coloured ions only, an 18 shell is built up.

TABLE III

Element		Oxyacids		No. of electrons in outer layer on basis of above theories
Titanium (4)	..	H_2TiO_3	..	8
Vanadium (5)	..	HVO_3	..	8
		H_3VO_4	..	18
Chromium (6)	..	H_2CrO_4	..	18
		H_3CrO_8	..	18
		H_3CrO_7	..	18
		$HCrO_5$	..	17
Manganese (7)	..	$HMnO_4$	..	18
		H_2MnO_4	..	18
Iron (8)	..	H_2FeO_4	..	18
Cobalt (9)	..	$H_2CoO_3(_3)$	..	18
Zinc (12)	..	H_2ZnO_2	..	18

(*b*) On the assumption that an 8 shell is built up, we cannot explain all the complex ions which are formed by the metals of the third series after titanium. On the basis of the 18 shell, we can explain all these ions by one hypothesis. Besides the above two modes whereby oxygen atoms may be held to the central atom, there is a third way—viz., (3) the oxygen atom may complete its outer layer to 8 by utilising its two inner electrons, and may then share a pair of electrons with the central atom, thereby contributing two electrons to its shell. In this mode of linking, the central atom gains just as many electrons as in mode 2, but there is the difference that more of the electrons of the central atom are left free to bind other oxygen atoms by mode 1.

Possibly mode 3 is to be preferred over mode 2, since this conception enables the highly oxygenated chromium complexes to receive explanation. In $\left[CrO_8\right]^{---}$ $\left[CrO_7\right]^{---}$ and $\left[CrO_5\right]^{-}$

we have four oxygen atoms held according to mode 3 and contributing 8 electrons, and 4, 3 and 1 atoms respectively, held by mode 1 and contributing no electrons. The fact that $\left[ZnO_2\right]^{--}$ is colourless needs some further hypothesis. Table III exhibits the oxyacids of some of the metals of the third series.

Halides

It is not often clear whether a metal forms true complex ions of any degree of stability with the halogens. We find the term " double salt " used more often than the term " complex salt " in describing compounds of the metals with the halogens. However, whatever the nature of these compounds may be, their formulæ usually correspond with those of the cyanides. The complex fluoride, H_2SiF_6, can be explained in terms of the present theory thus. Possibly here the fluorine atoms complete their outer layers to 8 by the help of one inner electron and then share two electrons each with the central atom, thereby contributing 12 electrons to its shell. These together with 2 electrons from the hydrogen atoms and 4 from the silicon atom make up 18 electrons round the silicon kernel. A similar explanation holds for K_3AlF_6.

INTERNATIONAL MINING EXHIBITION

The following papers will be read at the Oil Conference to be held at the Sixth International Mining Exhibition from June 4 to 8, 1923 :—

Monday, June 4, *a.m.*—" The Riddle of the Carpathians " (Opening Address), by E. H. Cunningham Craig, B.A., F.R.S.E., F.G.S., M.Inst.P.T. " Oil Deposits and the Tectonics of Vertical Pressure," by Dr. Maxmilian Kraus.

Monday, June 4, *p.m.*—" Note on the Genesis of Hydrocarbons and their Localisation in certain Zones of the Earth's Crust," by R. d'Andrimont.

Tuesday, June 5, *a.m.*—" Oilfield Waste," by A. Beeby Thompson, O.B.E., M.I.Mech.E.

Thursday, June 7, *a.m.*—" The Mode of appearance of the Petroleum Deposits in the Carpathian Region, with general consideration on the Genesis of the Petroleum and the Source of the Actual Deposits," by J. Voitasti, Professor, Cluj University.

Thursday, June 7, *p.m.*—" An Economic Study of Petroleum Mining by Underground Drainage," by Major J. A. Lautier, M.Inst.P.T.

Friday, June 8, *a.m.*—" The Standardisation Movement in America and its relation to and application towards the Elimination of Waste in the Petroleum Industry," by O. A. Young and S. D. Tuthill.

Friday, June 8, *p.m.*—" The Caribbean Oil Region," by George Howell, F.G.S., F.R.G.S., M.Inst.P.T.

THE DETERMINATION OF PARA-AMIDOPHENOL IN THE PRESENCE OF METOL

By W. F. A. ERMEN

In the course of our investigations on the preparation of metol (*cf. Chem. and Ind.*, May 18, 1923, p. 486), it was necessary to know the amount of this substance formed and the percentage of unaltered amidophenol and other bodies present in the mixtures.

The method we employed at first was to treat a dilute solution of our sample with excess of sodium acetate and benzaldelhyde. The benzylidene-amidophenol formed was filtered off, washed with a little cold alcohol, dried and weighed. With pure para-amidophenol the results obtained were very satisfactory, but for mixtures the process proved unreliable. It also failed to differentiate between metol and dimethyl amidophenol.

The method finally adopted was one suggested by Mr. L. E. Vlies :—About 2 grams of the sample is dissolved in 100 c.c. of water, with excess of hydrochloric acid, and N/10 sodium nitrite added until free nitrous acid can be detected. The amidophenol is thus diazotised and the metol converted into the corresponding nitrosamine, which slowly separates as white crystalline hairs. Sodium acetate is next added, followed by a known excess of metaphenylenediamine. This couples with the diazotised amidophenol, but does not affect the metol nitrosamine. The coupling process is rather slow, but may be accelerated by warming the mixture to about 25° C. When completed, the mixture is once more cooled, and the excess of metaphenylenediamine titrated back with a normal solution of freshly-prepared diazobenzene. Knowing the amount of diazobenzene required for the total quantity of metaphenylenediamine added, the difference between this and the quantity required for the titration of the sample gives the quantity that has been taken up by the amidophenol present. The total nitrite used for the first titration, less that required for the amidophenol found, gives the proportion of metol present. Dimethylamidophenol, if present, is not determined: sym. dimethylparaphenylenediamine reacts like metol, and will introduce a serious error if not previously removed by thorough washing of the sample with alcohol, in which the sulphate of this body is readily soluble.

The results obtained by this method are accurate to within 1 per cent., and a complete titration can be carried through in about half an hour.

* * *

On June 14. Professor Moureu will deliver an address on " Les Gazes Rares des Sources Thermales des Grisous et Autres Gazes Naturels," before the Chemical Society, at Burlington House, Piccadilly, W. 1. The address will be given at 8.30 p.m., not 8 p.m.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

THE NEW PRIME MINISTER

probably knows more about Chemical Industry than any former occupant of the office, and with the exception of Sir Alfred Mond, probably more than any other past or present Minister of the Crown. While President of the Board of Trade, Mr. Baldwin, with that thoroughness which has characterised all his public work, made a careful study of the position of the industry in this country in connexion with the Dyestuffs Act and the Safeguarding of Industries Act. He is one who misses no opportunity to make himself acquainted with the details of any industry, and both in the smoking room at the House of Commons, and at the Board of Trade he made constant inquiries as to the progress being made in this country. Some readers of these notes will also remember that he attended the annual dinner of the Association of British Chemical Manufacturers last year, and I am told that he put some very pertinent questions to his hosts. We cannot be satisfied that we have educated the public as to the importance of the industry until all our legislators as well as the general public are made to understand the facts of the case.

I OFTEN WONDER

how to estimate the value of publicity. It is a most interesting speculation. One thinks of the time when a restrained and dignified advertisement was all that could be considered useful; then of the growth of the shop window, the hoardings, the illuminated signs and sky-writing by aeroplanes. Of recent years publicity has become more subtle, and I suppose nothing has ever been attempted comparable with the propaganda carried on during the war; this left a mark on the art of publicity which persisted after the war, and to-day no project of any magnitude can be carried through without the subtle influence of the press. In a way it places more power in the hands of the press than was ever wielded by our most autocratic monarchs in days gone by. It used to be said that the platform would always ultimately beat the press, but I believe this is wrong, and power is with the party that controls the largest number of newspapers. One can only hope that the responsibility placed on the shoulders of the newspaper proprietors will be wisely used.

"CHEMISTRY AND INDUSTRY"

has its part to play in the leading of public opinion. The inspired paragraph in the public press has had its day, and the intelligent members of the public are beginning to discount the sometimes inspired letter to the newspaper. On the other hand, journals which are not too technical in character are being widely read, and are not open to the charge of manufacturing public opinion in the same manner as the daily press. The technical journal is expected to, and does, represent the views of the members of the Society for which it caters; this is honest, though partisan, statement of a case, and as such, the public reads it.

THE UNITED STATES TARIFF COMMISSION

is a body about which, up till now, we have had very little first-hand information. The visit of Mr. De Long, the head of the Chemical Division, and two of his colleagues, is the forerunner of what may prove to be some rather interesting experiences. The President of the United States has the power to vary the Tariff within certain limits on the recommendation of the Tariff Commission when application has been made in due form. Before arriving at any recommendation the Commission has to go through what looks like a very laborious process. First, it is necessary to ascertain the cost of production in competing countries, and obtain from the foreign manufacturer the cost of production in his country. Rather a delicate operation. At first, one would imagine that the Commission would be met with a blank refusal, but in practice this is not found to be the case. I believe those who are responsible for working the tariff in America are only concerned in placing the tariff at such a figure as will give the American manufacturer an even chance in the American market. The Tariff Commission will have, on the one hand, the importer who desires to obtain his goods in the cheapest market, and on the other, the American manufacturer who desires to establish his industry. The Commission must hold the balance between the two. If, therefore, the British manufacturer is likely to be penalised by the raising of the tariff at the request of the American manufacturer, he should be prepared to furnish in strict confidence the necessary evidence which would combat the demand for a raising of the American tariff. I cannot, therefore, see any other course for the British manufacturer to pursue than to state his side of the case, and supplement it with such evidence as is available.

IT IS INTERESTING TO NOTE

in this as in so many other public matters, how like our American cousins are to ourselves in their weaknesses as well as their strength. The cumbersome proceedings under the Safeguarding of Industries Act seem almost simple, when compared with the alterations of the American tariff. Imagine an enquiry with regard to Barium Peroxide, Potassium Chloride, Oxalic Acid and Veronal necessitating a visit to England, Germany, Scandinavia, Holland and Switzerland.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL MEETING

CAMBRIDGE. JUNE 20 TO 23, 1923

Addresses. The title of the President's address to be delivered on Thursday, June 21, is "Chemistry and Industry," and that of Dr. Charles Carpenter's address on the following day is "The Evolution of a Chemical Industry."

Accommodation of Members in Colleges. Accommodation will be available for men in various colleges from the afternoon of Wednesday, June 20, to the afternoon of Saturday, June 23. Members who arrive on Wednesday will be charged an inclusive fee of £3, those arriving on Thursday an inclusive fee of £2. These fees include the use of a set of rooms (bedroom and sitting-room), attendance, gratuities to college servants and the following meals: *Wednesday, June* 20.—Tea (if required) and dinner. *Thursday, June* 21.—Breakfast, lunch and dinner. *Friday, June* 22.—Breakfast, lunch and dinner (if required). *Saturday, June* 23.—Breakfast, and lunch (if required). Members will usually take their breakfasts in their rooms. Luncheon and dinner will be served in the halls of colleges. On Thursday and Friday tea will be served at the Vice-Chancellor's reception, and at the Garden Party at Sidney Sussex College respectively. Members who arrive before five o'clock on Wednesday, and who will require tea, are requested to give notice to that effect on a form to be supplied. There will be no extra charge. Members unable to attend the Annual Dinner of the Society on Friday, and desirous of dining in college that evening, may do so without extra charge by giving notice to that effect on the form above referred to. Members who do not make the trip to Ely, and who require luncheon before leaving Cambridge on Saturday, may obtain it in college on that day without extra charge.

It is important to note that alcoholic drinks are not included in the charges specified above, and members requiring such drinks with their meals must sign a chit presented by the waiter at the time of ordering. Payment for such must be made by members at the office of the Society at the Arts School, Bene't Street, on Saturday, before departure. It is the wish of the college authorities that no money shall change hands at table, and it is hoped that members will kindly co-operate in order that this scheme of payment may be a success.

To the list of colleges offering accommodation given on page 491 of *Chemistry and Industry* of 18th May, Corpus Christi is to be added. As previously stated, men requiring accommodation should communicate with Mr. J. E. G. Harris, the University Chemical Laboratory, Downing Street, Cambridge, who will supply any further information and forward a form to be filled up by the member.

Hotel Accommodation. There are still rooms available at The Bull and at The Blue Boar, but the other hotels are more or less full. There is good accommodation to be obtained in boarding houses (college rooms) should the supply of hotel rooms be exhausted.

The Smoking Concert on June 20 will be held in the dining room of the University Arms Hotel.

Group Photograph. A photograph of the members will be taken at the close of the Annual General Meeting on Thursday, June 21.

Tickets. Tickets for the Smoking Concert, the Reception and Dance, the Annual Dinner, and the excursion to Ely with lunch will be handed to members who have paid the inclusive fee when they register at the office in the Arts School, Bene't Street, Cambridge.

Guide to Cambridge. A copy of the illustrated Guide to Cambridge will be forwarded to each member who has purchased his ticket as soon as supplies are received from the publishers.

News. Further information will be published from week to week in *Chemistry and Industry.*

Members intending to be present at the meetings are asked to send in their forms with the appropriate remittance as soon as possible if they have not already done so, in order that adequate arrangements may be made for them.

Nominations to Council.—The following have been nominated under By-law 24 to fill four vacancies among the ordinary members of Council: Professor P. Phillips Bedson, Dr. R. T. Colgate, Mr. William Cullen, Professor A. R. Ling, Dr. Joseph Reilly, and Dr. E. W. Smith. A ballot list has been posted to every member entitled to vote.

J. P. Longstaff,
General Secretary

Central House,
Finsbury Square, E.C.2

ADVANCE PROOFS OF PAPERS

Authors of papers which are to be read before local sections or groups, may in some cases desire to have a few advance proofs for distribution among those likely to make useful contributions to the discussion. Any author who requires such advance proofs is requested to hand the manuscript of his paper to the Local Secretary so that it may reach the Editor at least *one month* before the date of the meeting at which it is to be read, in order to allow sufficient time for it to be considered by the Publications Committee and, if approved, set up in type.

UNION INTERNATIONALE DE LA CHIMIE PURE ET APPLIQUÉE

The programme provisionally arranged for the meeting of the International Union, to be held in Cambridge from June 16 to June 20, is given below :—

Saturday, June 16

Arrival of Delegates.

Sunday, June 17

4 p.m.—Reception by Sir Charles and Lady Walston at Newton Hall.

9 p.m.—Reception of the Delegates by the President and the British Federal Council.

Monday, June 18

10 a.m.—Council Meeting.

11 a.m.—General Meeting.

2.30 p.m.—Committee Meetings.

4.30 p.m.—Full Session. Presentation and discussion of a Report by Prof. J. W. McBain, "The Nature of Soap Solutions."

9 p.m.—Reception of the Union by the Master of Sidney Sussex College and Mrs. Weekes. Music.

Tuesday, June 19

10 a.m.—Council Meeting.

10.30 a.m.—Committee Meetings.

12 noon.—Presentation and discussion of a Report by Dr. E. K. Rideal, "Recent Developments in Contact Catalysis."

2.30 p.m.—Committee Meetings.

5.30 p.m.—Presentation and discussion of a Report by Prof. J. F. Thorpe, "New Aspects of Tautomerism."

Tea will be served in the gardens of Sidney Sussex College during the afternoon.

8 p.m.—Annual Dinner of the Union in the Hall of Trinity College.

Wednesday, June 20

10 a.m.—Council Meeting.

11 a.m.—Presentation and discussion of a Report by Prof. F. G. Hopkins, "Chemical Mechanisms Involved in the Oxidations which Occur in Living Tissues."

2.30 p.m.—General Meeting.

4 p.m.—Honorary Degrees. Ceremony at the Senate House.

5 p.m.—Reception by the Vice-Chancellor of the University at the Fitzwilliam Museum. Tea.

In addition to the British members of the Council of the Union Internationale the British Delegation will include, amongst others, Professors G. Barger, A. W. Crossley, H. B. Dixon, F. S. Kipping, J. W. McBain, J. F. Thorpe, Sir R. Robertson, and Messrs. E. F. Armstrong, E. R. Bolton, F. H. Carr, A. Chaston Chapman, A. Harden, J. A. Harker, T. H. Henry, C. T. Heycock, H. F. E. Hulton, C. A. Mitchell, R. H. Pickards, E. K. Rideal, E. W. Voelcker and W. J. U. Woolcock.

MEETINGS OF OTHER SOCIETIES

ACADÉMIE DES SCIENCES

At the meeting on April 30, Monsieur P. Brémond read a paper on the persistence or the re-appearance at high temperatures in ceramic colours of shades which are associated usually with unstable salts. As explanation, it was suggested that the coloration was due to the coloration of the ions of these salts.

A paper by Monsieur F. Michaud recorded the observation that on passing an electric current through a gel of gelatin, the gelatin contracted at the anode and swelled at the cathode, and the author suggested that muscular contraction might be explained by a similar mechanism.

On May 7, Messieurs Bordas and Touplain continued their paper on a new denaturant for alcohol. The authors showed that alcohol containing 1-20,000 part of creosote oil gave a fine blue coloration on treatment with baryta water or lime water.

Prof. A. Noyes, of Chicago, communicated a note on the decomposition of solids by light.

ROYAL MICROSCOPICAL SOCIETY

A meeting was held on May 16, 1923, Mr. E. J. Sheppard, vice-president, in the chair, and Mr. W. M. Ames, M.A., B.Sc., read a paper on "Applications of the Microscope in the Manufacture of Rubber."

The microscope can be used for the examination of pigments used in making rubber, and also for the examination of rubber itself. A special method (Green's) is available for making slides of pigments. The determination of average particle size can be carried out accurately (using Green's method) only for a few pigments, but the relative surface development of various pigments can be ascertained by means of the microscope. In addition to the two methods in use for preparing microsections of rubber, a third is suggested of vulcanising a sheet of rubber sufficiently thin to be used for microscopic examination.

The distribution of pigments in rubber is of great importance. Carbon black appears to form aggregates less readily than other compounding materials. Diminution in the quantity of free sulphur when rubber is caused to perish by being kept in a hot atmosphere, and alteration in the appearance of the sulphur formations is due to migration of the sulphur to the surface of the rubber and to evaporation. This does not take place in rubber allowed to perish in the ordinary way. When rubber under strain is examined, vacua are found between the separate units of sulphur formations, and at the poles of crystalline pigments, but no effect is noticeable in the case of zinc oxide or gas black; permanent internal deformation is visible in the rubber after retraction. The increase in solubility of sulphur in rubber with rise in temperature can be observed microscopically.

SOCIÉTÉ DES INGÉNIEURS CIVILS

On May 4, this Society celebrated its 75th anniversary at the Sorbonne in the presence of the President of the Republic and of numerous French and foreign technicians, the English delegates including Monsieur Paul Kestner, who represented both the Society of Chemical Industry and the Société de Chimie Industrielle, Sir A. Denny and Sir V. Raven. The opening address was delivered by Monsieur L. Guillet, president of the Society, and Sir V. Raven presented Monsieur Rateau with a Medal of the Institution of Mechanical Engineers. Monsieur R. Jordan in an address on the metallurgical industry, outlined the results and aims of the French factories, and numerous papers were read, ranging in subject from the uses of Hertzian waves, and the electrical resources of France, to aviation. Visits were paid to the aerodrome of Bourget, the Eiffel Tower, and the new electrical generating station at Genevilliers.

At a later meeting Monsieur A. Portevin presented a paper on magnesium and other ultra-light alloys. Monsieur Portevin showed that the use of light alloys in engineering, especially aeronautical, work has given to magnesium a definite place as a metallurgical product. To improve the mechanical properties of magnesium it is alloyed with aluminium, zinc, copper or cadmium, the choice of the type of alloy depending on the use for which it is destined. Magnesium alloys are well suited for use in engineering work as they can be easily worked in a variety of ways. For the reduction of the weight of machine parts ultra-light alloys as compared with light alloys play the same *rôle* as that of special steels compared with ordinary steels in mechanical construction.

FORTHCOMING EVENTS

June 4.	University College, University of London, Gower Street, W.C. 1, at 5.30 p.m. "Problems in Relativity," by Prof. H. A. Lorentz, F.R.S. Also on June 5 and 7.
June 4.	Society of Chemical Industry, *London Section*. The Chemical Society's Rooms, Burlington House, Piccadilly, W. 1, at 8 p.m. "The Stream Line Filter, with Demonstrations of the Filter in Operation," by Dr. H. S. Hele-Shaw.
June 5 to 8.	The Institution of Electrical Engineers. Summer Meeting at North-Western Centre.
June 5.	The Textile Institute, *Lancashire Section*. The Institute, Manchester, at 4 p.m. "Cotton and Some of its Problems," by W. R. Dunlop.
June 6.	University College, University of London, Gower Street, W.C. 1, at 5 p.m. "The Structure and Behaviour of the Molecule," by Prof. G. N. Lewis, Ph.D. Also on June 8 and 12.

CORRESPONDENCE

"CELANESE" ARTIFICIAL SILK

Sir,—In the note on "The Artificial Silk Industry," which appeared on page 432 of *Chemistry and Industry* of April 27, we observe that mention is made of "Celanese" artificial silk made from cellulose acetate. Will you permit us to point out that the word "Celanese" is the registered Trade Mark of our Company for artificial silk goods, both in this country and abroad, and that we are sole proprietors of this Trade Mark. In view of the importance of the Trade Mark to us we shall be much obliged if you will be good enough to publish the present letter in your next issue.—We are, Sir, etc.,

British Cellulose and Chemical
Manufacturing Co., Ltd.
M. P. Dickie, Secretary
8, Waterloo Place, London., S.W. 1
May 25. 1923

GASEOUS COMBUSTION

Sir,—*Calorifer's* remarks (in your issue of to-day's date) on the explanation given by Professor Bone of his results obtained with explosive mixtures of carbon monoxide, nitrogen and oxygen appear to me very sound. I might add that Professor Bone would seem to be unaware of the results obtained fourteen years ago by Haber and Coates when studying the products of combustion furnished by flames of carbon monoxide, nitrogen and oxygen burning under pressure.

At ordinary pressures, such flames yielded a trace only of nitrogen oxides—at higher pressures, proportions which more or less corresponded to true temperature equilibrium. The difference was connected by them with the much increased luminosity of these flames under pressure, a luminosity accompanied by increased ionisation and catalytic effect on the sluggish nitric oxide formation.

I recall these facts, because, after all, a flame is an explosion of sorts.—I am, Sir, etc.,

A. J. Allmand
King's College, University of London
May 25, 1923

PERSONALIA

The honorary degree of LL.D. will be conferred on Sir R. Robertson, Chief Government Chemist, at the graduation ceremonial at the University of St. Andrew's on July 6.

Dr. H. A. Curtis has been appointed to take charge of the investigation of nitrates in the U.S. Department of Commerce survey of essential raw materials produced under monopoly conditions abroad. The object of the investigation is stated to be to safeguard American consumers in obtaining adequate supplies at reasonable prices.

Amongst recent nominations to the Consulting Committee for Arts and Manufactures of France are J. Branet, manufacturer; E. Roux, director of the "Repression des Fraudes" R. Duchemin, president of the Union of Chemical Industries; E. Fleurent, director of the Office of Chemical Products, etc.

Monsieur J. Schneider, of the well-known firm of Schneider and Co. (Creusot) and Monsieur Aubrun, managing director of that company, have resigned from the directorate of the "Comité des Forges." Schneider and Co. still adhere to the Comité, but will take no further part in directing its work.

NEWS AND NOTES

FRANCE

Notes from Paris

A technical congress of the ceramic industry was held in Paris on May 14 to 18. The first day was devoted to the study of forced versus natural draught in ceramic furnaces. Monsieur Denisse discussed the advantages and disadvantages of the various furnaces and compared the tunnel and continuous ovens, and showed that the use of a fan increased production by 25 per cent. He concluded that a fan, whether employed for drying or for firing, was a valuable aid to the ceramic industry. During the discussion various speakers defended natural draught, and Monsieur Norroy in particular claimed that the use of forced draught was useless in connexion with Hoffmann ovens, and that it would be wrong to use it in every case. Monsieur Granger, chief of the Testing Laboratory of the Sèvres porcelain factory, then described improvements in the manufacture of plates and gave an account of modern plant and processes.

On May 15 Prof. L. Bertrand, of the École Normale Supérieure, spoke on the composition and structure of various clays and the changes they undergo on heating. Methods of microscopical examination were described, and it was shown how these could be used to give results with a precision unobtainable by chemical analysis; for instance, a microscope made it possible to ascertain the degree of firing of certain delicate ceramic products. The plasticity of ceramic materials was considered by Dr. Bigot, who said that colloidal plasticity was of vital importance in ceramics, and he described methods of measuring it, the variations it underwent during pressure and firing, and pointed out that processes of rapid manufacture should be preceded by laboratory studies on plasticity. An interesting paper on the costing of refractory products was contributed by Monsieur Bodin, who pointed out the necessity of laying down a definite quality of product for a given use.

On May 16 a general meeting was held, and on May 17 and 18 visits were paid to various factories.

CANADA

Titanium

Although the existence of titanium was discovered some 130 years ago, it was not isolated in a pure state until 1910, when Hunter produced the metal. Similarly, only in very recent years has any progress been made in the utilisation of titanium compounds, although various titanium compounds had been suggested for use as pigments as long ago as 1846. Ferro-titanium has, however, been utilised in the iron industry since 1895 and titanium white, a new pigment consisting essentially of titanium dioxide, is now being made. The useful report on "Titanium" by A. H. A. Robinson, published by the Department of Mines, Canada (Pp. 119, Mines Branch, Ottawa), discusses the manufacture, properties and uses of this new pigment, as well as those of other useful titanium compounds, and describes in detail the occurrence in Canada of large unexploited deposits of titanium ores that may in future become of great industrial importance.

Titanium is not rare; in fact Clark estimates that it constitutes 0·44 per cent. of the solid crust of the earth, ranging ninth for abundance among the elements, but the only commercial ores are rutile and ilmenite. In the province of Quebec there are large deposits of ilmenite that are readily accessible, can be cheaply mined, and seem capable of furnishing an output large enough to meet the probable demands for many years. In the past a few small shipments from these deposits have been exported to the United States for use in making ferro-titanium, but conditions are eminently favourable for establishing the manufacture of titanium white and other titanium compounds in Quebec, as the deposits are reasonably close to abundant supplies of hydro-electric energy and markets for the finished product. The monograph from which the above information is taken concludes with an interesting list of uses of titanium and its compounds, among which may be mentioned metallic alloys, filaments for incandescent lamps, paint pigments, dyes and mordants in the textile and leather industries, and refractory colouring materials in the ceramic industries. In addition certain titanium salts are said to be finding extended use on account of their great power as acid reducing agents, the oxide is said to form a very efficient catalyst in the esterification of acetic acid; titanium nitride has been suggested as a basis for fertilisers and as an abrasive, whilst the metal itself has been used in pyrotechny.

The Leather Industry in 1921

The Dominion Bureau of Statistics reports that in 1921 the number of tanneries was 119, 64 being in Quebec and 40 in Ontario. Statistics of the industry are as follows:—Value of output, \$22,905,528; capital invested, \$32,137,488; persons employed, 4208; cost of materials used, \$15,157.358; the principal products were sole leather 23,502,370 lb., and upper leather 34,896,226 sq. ft. Exports in 1922 increased in value to \$5,091,384 and the outlook for 1923 appears to be more favourable.

GERMANY

Production of Artificial Silk

Recent statistics show that in 1922 Germany produced 6000 metric tons of artificial silk. The average monthly output at the beginning of the year was 350 m.t., but by the end of the year it had reached 600 m.t. The average monthly export rose from 100 m.t. at the beginning of 1922 to 200 m.t. per month by the end of the year.—(*U.S. Comm. Rep., May* 7, 1923.)

Justus Liebig and Chemical Industry

Liebig, the 50th anniversary of whose death (April 18, 1873) has just been passed, possessed extraordinary technical interest and insight, as is clearly seen from letters written during his first journey in Great Britain and Ireland (in 1837) to his friend Wöhler. Nevertheless, he derived little financial gain from the results of his researches. He made, for example, no attempt to utilise his improved preparation of potassium cyanide (addition of potash to the molten ferrocyanide), or his preparations of aldehyde and chloroform. His suggestions for employing artificial fertilisers containing potassium, nitrogen and phosphorus, though received with enthusiasm in England, met at first with bitter opposition in Germany. Nor was his process for producing silver mirrors a commercial success, though it is nowadays extensively used, and the trouble he lavished on the production of a suitable baking powder passed practically unrewarded. Even from his perhaps best known achievement, commonly styled "Liebig's Extract of Meat," he derived but little remuneration, the greater part of the profits passing to an English firm of manufacturers. Liebig's indirect influence on chemical industry, especially in his own country, can, however, hardly be exaggerated. He and his school (which included Hofmann and Kekulé) were the first to show that it is not the empiricist but the chemist with a broad scientific education, the man who has learnt to think and work exactly, who is qualified to build up and advance a chemical industry. Finally, by his work on organic elementary analysis, he provided the groundwork for our modern organic chemical industry; by his study of plant nutrition he promoted the development of the synthetic fertiliser industry; and by his literary activities, in particular his chemical letters, he brought home for the first time to the general public something of the meaning of chemistry.—(*Z. angew. Chem., April* 18, 1923).

GENERAL

Institute of Chemical Engineers

The first Annual Corporate Meeting of the Institution of Chemical Engineers will be held on Friday, June 8, at the Engineers' Club, 39, Coventry Street, London, W. 1. The President, Sir Arthur Duckham, K.C.B., M.I.C.E., will take the chair, and after the formal business has been concluded, tea will be served. At 5.0 p.m., Mr. T. C. Finlayson, B.Sc., will give a short account of his paper on "Industrial Oxygen," which will be followed by a discussion. An informal dinner will be held in the Club at 8.0 p.m. Corporate members are invited to bring friends who are interested to the meeting, tea and dinner, but due notice should be given to the Hon. Secretary, Prof. J. W. Hinchley, 307, Abbey House, Victoria Street, London, S.W. 1.

The Influence of Road Dressings on Fish Life

The Standing Committee on Rivers Pollution (1921) has issued a report (No. 187, 1d.), which states that the results of numerous experiments show that the drainage from bituminous roads is without appreciable toxic effect on fish, due either to soluble materials extracted by rain from the bitumen itself or to colloidal particles derived from disintegration of the bituminous surface. The term "bitumen" is understood to include both hard bitumen or asphalt, and soft bitumen or malthas, so that a bituminous road surface may contain, without producing harmful results to fish, either natural bitumen or the pitch-like residue left when crude petroleum is fractionated. Mixtures containing pitch or other coal-tar products did not come within the scope of the investigation.

New Heating System for Chemical Works

The disadvantages of the use of radiators, hot-water pipes, etc. for heating large rooms require little elaboration. The initial heating up of large masses of iron and the subsequent currents of heated air ascending directly to the ceiling without warming the lower strata hardly tend towards efficiency. A considerable advance over previous systems appears to have been made in the "Thermon" heating apparatus, an account of which is given in a recent number of the *Chemiker-Zeitung* (1923, p. 361). Steam from any source, fresh or waste, or hot water, passes through a small battery of heating tubes enclosed in an iron box and air is circulated around the battery and out into the room by means of a powerful fan. The temperature of the battery can be regulated by means of dampers and the direction of the expelled warm air by adjustable shutters. The radiation is effective within a radius of 15–20 yards, and models are made giving 15,000–200,000 cals. per hour. The arrangement would appear to be a distinct improvement on its forerunners, from the point of view both of economy and hygiene.

REPORT

Report on the Economic and Financial Conditions in Belgium, December, 1922. *By* J. P. Bagge, *H.M. Commercial Secretary, Brussels.* Together with an Annex on the Economic Situation in the Grand Duchy of Luxembourg. *Department of Overseas Trade. Pp.* 79. *H.M. Stationery Office,* 1923. *Price* 2*s.* 6*d.*

Since the publication of the last report (*see* J., 1922, 318 R) the stagnation affecting Belgian economic life has passed, trade has revived and reconstruction is almost complete. In fact only 4 per cent. of the industrial wage-earners were unemployed in December, 1922, the proportion being high, however, in the chemical industry.

The number of blast-furnaces in operation doubled during 1922, and now amounts to two-thirds of the number in operation before the war, whilst production has increased from 250 to 300 per cent. The production of unrefined zinc practically doubled as compared with 1921. The situation in the glass industry improved continuously and producers have been finding difficulty in meeting demands. The present prosperity applies to all branches of the industry. In the chemical industry the general outlook is good. In view of the high costs of raw materials efforts are being made to curtail imports from countries with appreciated currencies. The demand for sulphuric, hydrochloric, and nitric acids is good, and the revival in the glass industry has led to a shortage of sulphate of soda. The soap industry, however, is in a bad way. Superphosphate is in demand though shortage of labour has retarded deliveries. The principal chemical products exported were sulphuric acid, valued at 32 million fr. and nitrate of soda, 55·7 million fr. A factory is being erected at Colen to treat radio-active minerals from the Belgian Congo.

During the early part of 1922 the coal trade was stagnant, but the coal strike in America improved the position by diverting British competition, and by September the demand was greater than the supply, the output being still below the pre-war average. Increased prosperity prevailed in the sugar industry, 63,630 tons being produced in October, compared with 38,116 t. in October, 1921.

Imports into Belgium in the first nine months of 1922 amounted to 6428·2 million fr., compared with 7727·0 million fr. in the corresponding period of 1921. Exports in the same periods amounted to 4298·8 million fr., and 5441·6 million fr., respectively.

In the annex dealing with Luxembourg the important metallurgical industry of this State is discussed. The situation, which was bad in 1921, improved last year, though at present the shortage of coke is a serious hindrance. In 1922, 1,685,700 t. of pig iron and 1,394.103 t. of steel were produced.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for May* 17)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Railway material, tyres ..	658
Belgium ..	Brass and iron	672
British India	Iron and steel, tubes, fittings (tender)	*
Canada ..	Pulp and paper	660
,, ..	Hardware, pig and sheet iron	662
,, ..	Silk	663
,, ..	Earthenware	11104/ E.D./M.C./ 2
Denmark ..	Oils, fat	673
Netherlands	Iron, brass	676
,, ..	Leather	677
Norway ..	Tinfoil	678
Palestine ..	Zinc, aluminium foil ..	†
South Africa	Glass	11230/E. D./M.C./2
,, ,, ..	Electric cable (tender) ..	11309/E. D./C.C./2
Spain ..	Chemicals, potash, phosphates	679
,, ..	Surgical instruments, rubber goods	7424/22/ F.L./C.C.
United States	Steel wire	19498/F. W./E.C./2

* Director-General, India Store Department, 10, Belvedere Road, London, S.E. 1.

† D.O.T., 35, Old Queen Street, S.W. 1.

TARIFF CUSTOMS EXCISE

Mexico.—The duty on imported pneumatic tyres, indiarubber tyres and inner tubes has been modified.

Poland.—The issue of May 24 contains a list of articles which are subject to surtaxes, among which are included oils, chemicals, minerals, iron and steel, leather, glass, building materials, paint, varnish, paper, etc.

Rumania.—Regulations regarding the exemption from, and credit in respect of, the payment of duties on sugar, have been issued.

South Africa.—A revised statement of the duty on patent medicines is given in the issue of May 24.

Yugoslavia.—Exports of fresh and dried beet and sugar-beet parings are now permissible, subject to duty.

REVIEWS

A Comprehensive Treatise on Inorganic and Theoretical Chemistry. By J. W. Mellor, D.Sc. Vol. III. *Pp.* $x+927$. *London: Longmans, Green and Co.*, 1923. *Price* £3 3*s*.

In the volume under review Dr. Mellor has continued on similar general lines the work so well begun in Vols. I and II of his book. Justly indeed is it termed a "comprehensive" treatise; contemplating the task which must be represented by its compilation one is at a loss whether to admire more the incredible industry or the sheer pluck of the author. Legends grow around the man who does such things; rumour has it that dictaphones, typists, card-indexes, and the other paraphernalia of modern "systems" play a vital part in this compilation, and perhaps the jade in this does not lie. But there is overwhelming internal evidence that the book, and the credit for it, is Dr. Mellor's. A great deal of the detail work may have been, indeed one would think must have been, delegated to assistants; but the author's hand is on every page. The publishers have dealt with the book in accordance with its merits: it is well printed in good readable type on sound paper and thoroughly well bound.

It will be remembered that Vol. I is occupied with a consideration of general chemical theory and the chemistry of oxygen and hydrogen, whilst Vol. II deals with the alkali metals and the halogens. This volume consists of the four chapters XXI-XXIV, dealing respectively with copper, silver, gold and the alkaline earths. Calcium, barium and strontium, as is obviously convenient, in view of their close chemical and physical similarity, are discussed together. Within the chapters, numbered sections are devoted successively to the history, occurrence, extraction, physical properties, chemical properties and atomic weights of the metals; and to the preparation and properties of their oxides, fluorides, chlorides, bromides, iodides, sulphides, sulphates, carbonates, nitrates and phosphates and groups of compounds derived therefrom. Several sections are frequently employed to discuss one part of the foregoing broad scheme and sections are inserted to cover special subjects, for example, the alleged allotropic forms of copper, hydrated and colloidal copper oxides, the action of light on silver halides, etc. The carbides, nitrides, phosphides, nitrites, sulphites, cyanides and a host of other compounds are omitted and will find their place in a later volume, just as the bromates, hypochlorites, etc., have already been described in Vol. II. The references appear at the end of each section, grouped in paragraphs, the connexion of the group of references with the text being indicated by superscript figures in the usual way.

The matter is carefully arranged, and well indexed, and heavy and italic types are judiciously used to emphasise key words in such a way as to guide the eye rapidly to the point sought. As in the earlier volumes, each topic is discussed in a most exhaustive fashion; a very searching study of the book leaves one with the impression that the number of cases where any point of interest has been slurred or omitted must be quite insignificant.

Much useful detail is given about methods of preparation, and in many cases the special methods which have been worked out for preparing substances in an unusual state of purity, *e.g.*, by Richards and his co-workers, are adequately described. Throughout the book frequent and effective use is made of diagrams, on a small but sufficient scale, to illustrate the relations in binary and ternary systems. In general, no attempt is made to describe technical processes as such, though their chemistry is fully discussed, and this principle is obviously appropriate to a text-book of pure chemistry.

Special commendation must be given to the statement of physical properties, whether of metals or of their compounds, and to the description of the chemical reactions of each substance. As an example, the section on the chemical properties of copper occupies 34 pages whilst the references thereto fill six pages of very solid small type; and the whole is full of the most interesting detail, of which by far the greater part must be new to any one chemist. The book fulfils the promise of the earlier volumes in being, as a whole, extraordinarily readable. Serious students of chemistry, young and old, may be advised to make hearty meals of this good meat; provided they have the common sense not to try to eat the bones, they will inevitably derive both pleasure and much solid nourishment. One misses, however, as section headings, the apt and often amusing quotations we have learned to expect from the author: presumably the demand has outrun the supply.

One is tempted to quote many parts of the book, but space forbids. The old speculations as to the means whereby Moses reduced Aaron's golden calf to ashes are reported, and dismissed with a characteristic quotation from Socrates. A most interesting account is given of the phosphorescence of the sulphides of the alkaline earths. Under the density and structure of copper there is a good discussion of the amorphous and crystalline states in metals; and by taking together a section on colloidal copper oxides and several sections in the chapter on gold one has a fairly thorough account of colloidal solutions in general. This list could be prolonged almost indefinitely, but enough has perhaps been said to convey some impression of the solid excellence of the book.

It obviously offers so large a target that some part of it must inevitably be vulnerable to criticism, and it may be permissible and useful to consider some apparent blemishes; but only upon the clear understanding that they are, in the reviewer's opinion, negligible as compared with the positive merits of the book: criticism otherwise would simply be unfair to the author.

Misprints and clerical errors can be found, but their scarcity is remarkable. A few matters might have been omitted: *e.g.*, on p. 45 we find the times required for stated currents to melt copper wires of various thicknesses, data which should be relegated to an engineer's pocket book. Omissions are harder to find, but one which may be noted is that the discussion of the atomic weight of silver contains no reference to the work of Richards and Willard on the combined ratios $LiClO_4$: LiCl and LiCl : AgCl, which give perhaps the best figure for the silver : oxygen ratio. In some few cases there is a duplication of statements, one of the worst being on p. 46 where, separated by four lines only, we find "H. C. Greenwood found the b. pt. of copper to be 2310° (760 mm.)" and "H. C. Greenwood found the *vapour pressure* to be 1 atm. at 2310°." This duplication seems the more irritating by reason of the repetition of the name.

Possibly the reviewer has an idiosyncrasy in this matter, but his one solid complaint about the book is upon this matter of names. The initials are a minor matter—most sensible chemists have only one or two. There is, of course, a jerk when one meets: "R. Luther electrolysed H. von Fehling's soln." (Yes, this *is* ordinary Fehling's solution), but this happens infrequently and does not really matter. The real trouble is just names: singly, and in pairs, triplets and platoons, they are dotted over every page until at times one inevitably receives the impression, the more unfortunate because so unfair, of fragments of chemistry floating in a sea of surnames.

Now the cause of this trouble is the system whereby references are grouped, often in twenties and thirties, so that the name is necessary to locate the reference within the group. Evidently individual numbering of references would run into big numbers, but even so, surely there would be much saving of space and increase in clarity. As it is, one finds very frequently the statement that certain matter "has been studied by" a string of half a dozen names, or even "M. Prud'homme made some observations on this subject"; whereas a single number and the magic words "see also" would dismiss the lot to the end of the section, where undoubtedly they belong.

Evidently, however, these criticisms are either upon matters of opinion or else upon points of minor importance, and detract nothing from the merits of the book. It is very true of this volume, as of its predecessors, that it is not merely a work of reference: it is that and much more. Though comprehensive, to the uttermost meaning of that word, it is a real text-book which every chemist should possess, so that he may enjoy the pleasure and profit of its frequent study and also secure its full value as a work of reference.

H. V. A. Briscoe

Glue and Gelatin. *By* Jerome Alexander. *American Chemical Society, Monograph Series. Pp.* 236. *New York: The Chemical Catalog Co., Inc.*, 1923. *Price* $3.

The volumes of the series of Monographs, published under the auspices of the American Chemical Society, are intended to serve two distinct purposes, viz., firstly, to present the knowledge available upon the chosen subject in a readable form, intelligible to those whose activities may lie in wholly different directions, and secondly to promote research by furnishing a well-digested survey of the work already done. The present volume is admirably adapted to serve these purposes. It is divided into fourteen chapters and an appendix. The first nine chapters, or 129 pages, are devoted to the chemical and physical properties of gelatin; twenty pages to the manufacture of, and the remainder to the uses and grading of glue and gelatin. A description of fish glue and isinglass is also given. It is impossible to deal adequately with so many subjects in such a small space, and the book suffers somewhat in consequence. The chemistry of gelatin and glue is treated very ably, and, as in Bogue's recent book, considerable stress is laid on the importance of hydrogen-ion concentration. In discussing the question: "Is gelatin a distinct chemical entity?" the author concludes that no one has hitherto made or experimented with chemically pure gelatin. Since this is so it is a pity, as he states, that so much of the recorded work has been done with gelatins of varying constitution, even the ash and water content rarely being stated. According to Alexander much of the published work should be repeated upon a standard or ash-free gelatin. This is all very sound advice. The chapter on the viscosity of solutions of glue and gelatin, and the factors which affect this constant are of practical interest to the glue chemist or manufacturer.

In dealing with collagen and ossein the author treats of chondrin as a body quite distinct from ordinary gelatin, though he quotes Mörner's experiments which tended to prove that it is readily converted into gelatin and mucin. The reviewer (J. 1910, 662) confirmed Mörner's work by preparing normal gelatin from cartilage. The method of preparation of chondrin so commonly copied from Allen should be scrapped. The section devoted to the chemical examination of glue and gelatin is good, but the co-precipitation of arsenic with phosphoric acid in the presence of organic matter is open to criticism. The methods given for the determination of lead, copper and zinc require some modification now that aluminium vessels are so commonly used.

Alexander, like all American authors, refers to Peter Cooper standards which are not used by English chemists, but he admits that nothing has been published regarding their origin and that they are perfectly arbitrary in nature. The only disappointing part of the book is the chapter devoted to the manufacture of glue and gelatin, though it serves to emphasise the fact that the chemistry of gelatin still remains a totally distinct subject from the chemistry of glue manufacture. The colloidal chemist tries to get pure gelatin for his experiments, rejecting all the concomitant impurities. The manufacturer, on the contrary, does not even desire to make a pure product, and sells the impurities at the price of the glue. The first question that one is asked, when recommending any alteration in methods with a view of improving quality is: How will it affect the yield? and the second is: Will it mean increased "handling" of the material? The time will come when the application of the principles of colloidal chemistry will be used to control manufacture, but much work is required before this ideal can be reached. Books such as this and Bogue's are of the greatest use, because they give us a good knowledge of the chemical principles involved and indicate, though they do not solve, the difficulties the manufacturer has to contend with. They mark, in fact, the dawn of a new era in the technology of gelatin. The two books will serve different purposes. Bogue's is the best "treatise" we have on the subject, while Alexander's does not attempt to be more than is indicated above, namely, a "compendium," useful chiefly to chemists capable of undertaking research work. It is rather curious that the author should, under these circumstances, devote four pages to explaining the meaning of hydrogen-ion concentration, though it is done excellently.

S. R. Trotman

Leitfaden der Quantitativen Analyse. *By* Dr. F. Hahn. *Pp. viii*+230. *Dresden and Leipzig: Theodor Steinkopff,* 1922. *Price: paper* 6*s.*; *bound,* 7*s.* 2*d.*

This volume possesses certain features which differentiate it from the usual run of text-books dealing with quantitative analysis. It is divided into sections dealing with gravimetric, volumetric and colorimetric methods of analysis and with electrolysis and gas-volumetric methods. The theoretical considerations underlying these various divisions are brought together in the first part of the book, and constitute a very clear exposition of the principles and practices of quantitative analysis, the theory of volumetric analysis, including the theory of indicators, being particularly well treated. One is struck by the many practical suggestions for simplifying and improving manipulative technique embodied in this theoretical section, which combines in a very happy way pure theory and manipulative "tips." In dealing with the determination of cations and anions, the procedure adopted is to take each metal or acid radicle and preface the account of its gravimetric determination with a list of compounds in which it is quantitatively precipitatable and the corresponding compounds in which these are weighable, with a direct reference to its volumetric, colorimetric, electrolytic or gas volumetric method of determination in the appropriate sections, where such methods are grouped together.

All methods are given very briefly, and copious references are given to the literature of the method where the author is not able to give sufficient details in the limited space he allots to each determination. The volume gives one the impression that the author was restricted to a limited number of pages, and that he has endeavoured to keep to this limit by discarding superfluous and wordy descriptions whilst retaining all essentials. In this he has been very successful, and the result is in pleasant contrast to the padded volumes usually met with. The book does not treat of the analyses of technical products. The illustrations are mostly crude in the extreme, and greatly detract from the merits of the book.

T. Callan

Flavouring Materials, Natural and Synthetic. *By* A. Clarke. *Oxford Technical Publications. Pp. xxi*+166. *London: Henry Frowde and Hodder & Stoughton,* 1922. *Price* 8*s.* 6*d.*

This little volume is intended as a guide to manufacturers of beverages and foodstuffs who have occasion to use natural and artificial flavouring materials. In a short introduction the author deals briefly with the anatomy and physiology of the nose and palate and gives an elementary account of recent theories on the connexion between the taste and smell of substances and their chemical constitution.

The main portion of the book is divided into four sections:—(1) Spices and condiments and other flavouring substances of animal and vegetable origin. (2) Essential oils. (3) Floral perfumes, fruit juices and compounded flavours for special purposes. (4) Odorous chemical products.

The first section embraces all the spices in common use and gives in each case some account of their origin, the chemical substances to which their flavour is due and the adulterations to which they are subject. It contains a useful collection of analytical constants and official standards and limits (where such exist) not only of the substances themselves but of the adulterants likely to be found in them, with, in the pages devoted to the spices, a short paragraph on the structures of diagnostic value visible under the microscope. The illustrations of these are not very satisfactory, the more so as no indication of the degree of magnification is given.

Section II, on essential oils, gives a good and comprehensive account of a wide range of these oils, their origin and chemical and physical characters, and also briefly describes the chief processes by which they are obtained and the methods adopted for their analysis.

The next section (Floral perfumes, fruit juices, etc.), is not quite so satisfactory. The methods of production are hardly described in sufficient detail and although there may not be many published figures relative to the composition of fruit juices, that hardly justifies their total omission. The chapter on compounded flavours contains a number of recipes which will no doubt be useful to those for whom the book is mainly intended.

The final section deals with numerous odorous bodies, many of them of synthetic origin, the information given being sometimes limited to the name of the substance and the odour it bears, whilst in others there is an account of the origin, preparation, physical constants and mode of assaying.

As will be gathered the work is somewhat unequal and has the defects attendant on extreme condensation. In the description of analytical processes the details are hardly sufficient for those without some acquaintance with this sort of work, but this defect is obviated to some extent by numerous references to current literature. In the chapter on the spices the calcium-carbide method for the determination of water might well have been mentioned, and it is a pity that the diastase and acid conversion methods for starch estimation should have been referred to as if they were of the same value.

There are very few printer's errors, but an unfortunate one on p. 28 causes the ash *soluble* in hydrochloric acid to be described as " sand." As a whole the book is clear, accurate and, for its size, remarkably comprehensive and with such full chapter headings and the index it is extremely handy to refer to. The clear type and excellent paper make it a credit to author and publisher alike.

CECIL H. CRIBB

INSTITUTE OF CHEMISTRY

We are asked to announce that the Council of the Institute of Chemistry of Great Britain and Ireland advises any Fellow or Associate of the Institute who may contemplate accepting appointment as Public Analyst for the County of Gloucester or for the City of Gloucester on the terms recently advertised to communicate at once with the Registrar.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Whitsuntide holidays have naturally affected trading adversely during the last fortnight. Apart from the expected reduction of business from this cause, however, there has also been a tone of depression for which it is a little difficult to account. Political unsteadiness both at home and on the Continent reacts so quickly on trade that this may be the cause, and if so an early revival of confidence may be expected. The competition of Continental imports is not of very much consequence in most directions to-day as the prices of such are on similar lines to home produced products.

Acetic Acid, 40% tech.	£24-£25 per ton. Still very firm with little available supplies.
Acid Hydrochloric ..	4s.-5s. per carboy d/d.
Acid Nitric 80° Tw. ..	£24 10s. per ton. Quiet.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d.-£8 per ton.
Arsenic (White) ..	£70-£72 per ton. Not much business passing.
Bleaching Powder ..	Spot £11 7s. 6d. d/d. ; Contract £10 7s. 6d. d/d. Keen competition for orders, especially export.
Bisulphite of Lime ..	£7 per ton, packages extra.
Calcium Chloride ..	£5 17s. 6d. per ton d/d. Very quiet.
Copper Sulphate ..	£27 per ton.
Potash Caustic	£34-£35 per ton. Slightly easier.
Potass. Bichromate ..	5¾d.-6d. per lb. d/d.
Potass. Chlorate ..	3d. per lb. Somewhat firmer but very quiet.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d. ; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76% ..	£20-£21 per ton. Quieter.
Soda Crystals	£5 10s. per ton carr. paid stations ; £5 at certain ports—Home trade.
Sod. Acetate 97/98% ..	£26 per ton.
Sod. Bicarbonate ..	£10 10s. per ton.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	2⅞d.-3d. per lb. Small demand.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, conc. ..	£16 per ton carr. paid. Little doing. Keen competition for export orders.

Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£26-£28 per ton according to quantity.
Carbon Black	1s. 5½d. per lb. ex wharf. Still very scarce.
Chromium Oxide	1s. 5d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb. Firmer on advance in price of Rape Seed Oil.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood-distillation products. Brown sugar of lead has still further advanced.

Acetate of Lime—		
Brown	£10 15s. per ton d/d.	
Grey	£22 per ton d/d.	
Liquor	9d. per gall.	32° Tw.
Charcoal	£9 10s.-£10 10s. per ton.	
Iron Liquor	1s. 6d. per gall.	32° Tw.
	1s. 2d. „ „	24° Tw.
Red Liquor	1s. 3d. „ „	14/15° Tw.
Wood Creosote	2s. 7d. „ „	Unrefined.
Wood Naphtha—		
Miscible	6s. 9d. „ „	60% O.P.
Solvent	5s. „ „	40% O.P.
Wood Tar	£6 per ton d/d.	
Brown Sugar of Lead	£45 per ton d/d.	

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 5d. per lb. Little movement in the market.
Crude 60's	3s. 6d.-3s. 9d. per gall. Market weaker.
Acid Cresylic—97/99	2s. 2d.-2s. 5d. per gall. Market quiet.
Pale 95%	2s.-2s. 4d. per gall. Not much demand.
Dark	1s. 10d.-2s. 1d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	9d.-11d. per gall. Not much demand.
Unstrained	8¾d.-9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8½d. per gall. Business slack, abundant supplies.
Pure	2s. 2d.-2s. 3d. per gall.
Toluole—90%	1s. 9d.-2s. per gall.
Pure	2s.-2s. 6d. per gall. Not much inquiry.
Xylol	3s.-4s. per gall. according to quality. Good demand.
Creosote—	
Cresylic 20/24%	11¼d.-1s. per gall. Not much business.
Middle Oil Heavy Standard Specification	8½d.-9½d. per gall. Market steady.
Naphtha—	
Crude	9d.-9¼d. per gall.
Solvent 90/160	1s. 7d.-1s. 9d. per gall. Fewer inquiries.
Solvent 90/190	1s. 5d.-1s. 8d. per gall. Market steady.
Naphthalene Crude—	
Drained Creosote Salts	£8-£8 15s. per ton.
Whizzed or hot pressed	£11 10s.-£14 per ton. Plenty of inquiries.
Naphthalene—	
Crystals	£18 per ton.
Flaked	£16 10s. per ton.
Pitch, medium soft	No business for this season. Prices for Autumn delivery 130s.-145s. per ton.
Pyridine—90/140	11s.-12s. per gall. More inquiry.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

A slight falling off of business in dyestuffs is fully accounted for by the Whitsun holidays. Orders for forward delivery have been coming in fairly well and still further improvement is anticipated. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 9d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.

m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works. Good demand.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Business has been fairly good during the week and improvement is expected in the near future as stocks become depleted. Very little in the way of fresh supplies can be expected from the Continent at present.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. 3d.-3s. 4d. per lb. Steady demand.
Acid, Benzoic	2s.-2s. 9d. per lb. Still very scarce.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton. Prices reduced by £5 per ton.
Acid, Citric	1s. 9d. per lb., less 5%. Less demand.
Acid, Gallic	3s. per lb. Steady demand.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb.
Acid, Salicylic	2s. 3d. per lb. Firmer.
Acid, Tannic	3s. 6d. per lb. Slightly dearer.
Acid, Tartaric	1s. 4d.-1s. 4½d. Demand good.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d. per lb.
Amidopyrin	14s. per lb. Little inquiry.
Ammon. Benzoate	3s. 6d. per lb.
Ammon. Carbonate B.P.	£32 15s. per ton. Price reduced by £4 15s. per ton.
Atropine Sulphate	12s. per oz.
Barbitone	Quoted up to 20s. per lb. Very firmly held. Higher prices quoted for forward delivery.
Benzonaphthol	4s. 6d. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Bromides	Better inquiry. Prices steady. Potass. 8d., Sod. 9d., Ammon. 10d. per lb.
Calcium Lactate	2s. 9d. per lb. for best makes.
Chloral Hydrate	4s. 3d. per lb. now wanted. Firmer tendency.
Chloroform	2s. 3d. per lb. for cwt. lots, ton lots being quoted down to 2s. per lb.
Creosote Carbonate	10s. per lb., with little inquiry.
Formaldehyde 40%	£90-£92 per ton. Very firm.
Guiacol Carbonate	8s. 6d. per lb.
Hexamine	4s. 3d. per lb.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Market good with considerable inquiry.
Magnesium Carbonate—	
Light Commercial	£37-£38 per ton net, according to quantity.
Magnesium Oxide—	
Light Commercial	£85 per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	1s. 8d.-2s. per lb. Good demand.
Menthol	35s. per lb. spot.
Methyl Salicylate	2s. 6d. per lb. for carboys. Not quite so firm.
Methyl Sulphonal	15s. per lb.
Mercurials	Unchanged. Market quiet.
Paraformaldehyde	3s. 6d. per lb. would now be accepted.
Paraldehyde	1s. 7d. per lb. Very steady. Forward prices show a higher tendency for best makes.
Phenacetin	6s. 6d. per lb. spot value. Better inquiry.
Phenazone	7s. 6d. per lb. Very firm.
Phenolphthalein	6s. per lb. now wanted by most holders.
Potass. Bitartrate—99/100% (Cream of Tartar)	98s. per cwt., less 2½%. Demand not quite so good.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. Demand still continues good.
Potass. Permanganate	10d. per lb. for large quantities. Forward market very much firmer.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	6s. per lb.
Salol	3s. per lb. now asked.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 9d. per lb. now wanted by holders. Still in short supply, fresh stocks being quickly absorbed.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality.
Sod. Hyposulphite—Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d. per cwt. Fairly good demand.
Sod. Salicylate	In good demand. Values unaltered, being 2s. 9d. per lb. for Powder, 2s. 11d. per lb. for Crystal. These prices show very little profit to the makers, and higher rates are mentioned for forward delivery.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. per ton, according to quantity for home trade, 1-cwt. packages included.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.

Thymol	.. In view of fairly large stocks being held keen competition still exists to obtain orders. The value of genuine good White Crystal remains at 17s. per lb.

PERFUMERY CHEMICALS

Acetophenone ..	.. 10s. 6d. per lb.	
Aubepine ..	.. 14s. ,, ,,	
Amyl Acetate ..	.. 3s. ,, ,,	
Amyl Butyrate ..	.. 7s. ,, ,,	
Amyl Salicylate	.. 3s. 6d. ,, ,,

Wayne County	.. 13s. ,, ,,	
Japanese ..	.. 6s. 4½d. ,, ,,	
Petitgrain Oil ..	.. 7s. 9d. ,, ,,	Lower.

TRADE NOTES

Trade Information

The Calorizing Process.—We have received an interesting booklet describing the process and varied applications of calorizing. This process consists in forming a surface alloy of aluminium on ferrous and non-ferrous metals, by subjecting them to a high temperature in an atmosphere of hydrogen in an airtight retort partly filled with a mixture of finely divided metallic aluminium suspended in aluminium oxide. The depth of alloy formed depends on the duration of the treatment and the composition of the mixture, but it is quite homogeneous. The pamphlet gives an account of the physical properties of calorized metals and discusses the application to various metals and a variety of industrial articles. Further information can be obtained from the Scarab Oil Burning Co., Ltd., Calorizing Department, Carlton House, Lower Regent Street, London, S.W. 1.

A New Electrical Generator.—The British Thomson-Houston Co., Ltd., inform us that a 40,000-h.p. generator, the largest power-generating unit in the United Kingdom, and made by the Company, was started recently at the Electricity Works of the Rotherham Corporation. The set comprises a 40,000-h.p. turbine which runs at 15,000 revs. per minute, and drives an electrical generator which develops 30,000 kw. A.C. at 6600 volts.

PUBLICATIONS RECEIVED

The Manufacture of Acids and Alkalis. *By* Prof. G. Lunge, Ph.D. *Completely revised and re-written under the editorship of* A. C. Cumming, O.B.E., D.Sc. *London: Gurney and Jackson*, 1923:—

Vol. I. Raw Materials for the Manufacture of Sulphuric Acid and Sulphur Dioxide. *By* W. Wyld. *Pp. xiii*+558. *Price* 36*s*.

Vol. V. The Manufacture of Hydrochloric Acid and Saltcake. *By* A. C. Cumming, D.Sc. *Pp. xv*+423. *Price* 31*s*. 6*d*.

Theoretical Chemistry from the Standpoint of Avogadro's Rule and Thermodynamics. *By* Prof. W. Nernst, Ph.D. *Revised in accordance with the eight-tenth German edition by* L. W. Codd, M.A. *Pp. xx*+922. *London: Macmillan and Co.*, 1923. *Price* 28*s*.

Absorption of Nitrous Gases. *By* H. W. Webb, M.Sc., F.I.C. *Pp. viii*+372. *London: E. Arnold and Co.*, 1923. *Price* 25*s*.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JUNE 8, 1923 No. 23

EDITORIAL

ONE of our correspondents has sent to us some specimens of propaganda leaflets directed against the French and sent out with German chemical journals which are controlled by the German Chemical Society. This policy seems to us to be unfortunate ; let us so far as possible keep science and politics—at any rate, foreign politics—apart. This cannot be done completely, of course, but let us do it so far as possible. The Germans have circulated a number of gruesome photographs ; we cannot complain of this, what we do complain of is that they shall be circulated by a learned Chemical Society as a piece of political propaganda. We hope that the Belgian and French Chemical Societies will not retaliate by circulating some equally unpleasant photographs taken a few years ago at Termonde, Dinant, Louvain and some other places. There is every reason why a chemist should be patriotic. Pasteur was a great patriot as well as a great chemist, but then he was a great man. But let learned societies in their publications try so far as possible to keep to the subject with which they are identified ; some political references are occasionally necessary, as affecting problems of chemical manufacture or as items of news which may specially appeal to a small and select body of readers. Surely the issue of such propaganda by the German Chemical Society does that Society no good and does Germany no good. In the interests of that civilisation which chemistry does so much to promote we appeal to all scientific societies in every country to do nothing which will add to the bitterness which already exists. The Germans perhaps do not realise that to make use of German chemistry for political purposes is a policy which does not find favour in most countries. We are perfectly convinced that such a policy does infinitely more harm to Germany than good. The essence of science is the zeal for truth ; truth and bias cannot be reconciled ; political propaganda is necessarily, and quite properly, biassed. That the science of a great nation may be suspected is a very grave circumstance ; and in the case we are considering the effect is quite insignificant and futile from the point of view of politics. It will be better for German politics and for German science if their respective publications are kept rigidly apart and we urge chemists of all nations to consider carefully whether it will not necessarily degrade the science from its high position if it is to be made use of as an advertising medium on political questions.

* * *

It is announced in *Nature* that Dr. Aston has developed a new method of obtaining mass-spectra of the light elements ; the results so obtained confirm the data already published by Aston and by Dempster. The difficulties of obtaining mass-spectra of many of the elements of high atomic weight are very considerable, but no doubt in time our knowledge of these will be greatly extended and when it is possible to compare the mass-spectra of all the rare earth elements a singularly interesting problem will have been solved. Mass spectra, X-ray spectra and the ordinary light spectra have all contributed to our knowledge of physical and theoretical chemistry. What new spectra shall we be able to investigate a hundred years hence ? What sort of a table of atomic weights and statistics will be published by the International Committee of the elements even fifty years hence. There is one little problem which will require its attention at no distant date in connexion with the new element hafnium. Is hafnium identical with Urbain's celtium ? If so what should it be called ? Messrs. Coster and Hevesy have made an important discovery and it has received a well-deserved measure of public interest and attention. On the other hand we do not remember that Professor Urbain has ever abandoned his claim to have discovered and named an element which should occupy the seventy-second house in the long street of chemical elements. These conflicting claims are the more delicate because both the French and the Danes will feel a just pride in their share in the achievement and neither nation will be inclined to abandon a name specially selected to honour the country of origin in favour of a name specially selected to honour some rival country. We are glad to think that it will not fall to our lot to study the minute details of this intricate piece of chemical history and summarise the evidence on both sides. But we suppose someone will have to worry out this little matter before very long.

* * *

Hardly anything in this world is so important as etiquette. We are therefore very grateful to a Cambridge correspondent who has furnished us with some kindly hints. Perhaps dress plays as important a part as behaviour in the minds of many people, and the rules as to dress vary as one travels from place to place. Our obliging correspondent informs us that one ought not to take as an example the Don who apologised for attending a College feast minus a collar, because it was in the wash. This incident belongs to some years ago, and even those who wear beards should dress remembering that our clerical friends lay stress on the reality of the unseen. We are informed that unless one is a College porter and *ex-officio* entitled to the distinction, one should not wear a silk hat in Cambridge; nor are frock coats or morning coats expected at garden parties, receptions or meetings. Visitors do not wear academic dress at Cambridge; it simply is not done. Those dining in the Hall do not wear evening dress unless the occasion is a special banquet or the dinner is to be followed by some entertainment which imperatively calls for evening dress. Visitors staying in College are expected to walk round the quadrangle in scanty raiment when seeking a bath before breakfast. In no circumstances may anyone walk on the grass in the quadrangles. The lawns here and in some of the gardens have been rolled and mown for several hundred years and are to be admired, not used for exercise. A number of minor points of difficulty have been indicated, and every visitor to Cambridge should take an early opportunity of learning the traditions. A new M.P. once asked Mr. Dillon how to learn the rules of the House of Commons. The reply was, " Break them ! " This is what Calorifer calls the heuristic method, but the rule about walking on the grass is an exception, even for experimental and heuristic purposes this feat must not be attempted.

PASTEUR CENTENARY CELEBRATIONS

By H. LLOYD HIND, B.Sc.

It was an honour for a simple member of the Society of Chemical Industry to find himself, in the picturesque French phrase, a " personnalité," guest of the French Government, and associated with the learned of the world in doing homage to France's great scientist, Pasteur. The *fêtes* were much more than the centenary of the birth of Pasteur; they were in truth a celebration of the fraternity of science in all countries. Pasteur stands for the spirit of French science in a way that no other man does, and probably in no other country is such a representative figure known. His name marks a new epoch in medicine and industry, indissolubly linked with that of his beloved country, but the benefits of his work have spread worldwide. It was fitting that the French Government should take this chance of consolidating foreign friendships by the chain he forged: a chain whose links are the bonds that bind humanity in a common effort to stamp out disease and misery.

Delegates have come from East and West, from America to China, representing Governments, universities and scientific societies, united in their sympathy with France and their desire to honour her famous son whose guiding stars were patriotism and humanity. The celebrations have taken many forms, solemn ceremonies and entertainments. Received in the gorgeous rooms of the Elysée Palace by the President of the Republic and his gracious wife, the delegates were at once set at their ease and made at home. There was no sign of the coincident Cabinet crisis as M. Millerand turned from the heavy duties of his office to welcome the guests in the name of France. There old friendships were renewed as visitors from one continent met those from others, as they settled down to enjoy the entertainment provided in the brilliantly-lit Grand Salon. It is perhaps to be feared that the words of the scene from Molière were lost in the babel of whispered conversation, but the dances by members of the ballet from the opera were understood and appreciated by all.

The following two days were given up to solemn and moving commemorative ceremonial. Meeting at the Institut Pasteur, the monument the master lived to see raised to crown his work, and where he lies buried with the simple statement of achievements as his noble epitaph, the delegates visited the scenes of his later work, saw his apparatus and stood before his tomb adorned with wreaths and flowers among which one bore the inscription :—

> From His Britannic Majesty's Government with deepest admiration and profound gratitude to a great savant to whom mankind owes so lasting a debt of beneficence.

The afternoon saw the climax of the Paris celebrations; the meeting in the great theatre of the Sorbonne presided over by the President of the Republic, when orations in honour of Pasteur were delivered by the Rector of the Academy of Paris and by the Ministers of Education and Hygiene, and addresses were presented by the representatives of Governments and universities, including Sir Charles Sherrington and Sir Anthony Bowlby, representing the Royal Society and the Royal College of Surgeons respectively. Amongst those present were Brigadier-General Leishman, representing the War Office; Sir W. J. Pope, K.B.E., and Prof. H. E. Armstrong, representing the Chemical Society; Mr. A. Chaston Chapman, representing the Institute of Chemistry; Professors H. B. Baker, A. Findlay, and T. M. Lowry; and Messrs. J. M. Lones and Lloyd Hind, representing the Institute of Brewing. Feeling was intensely stirred by the music of the "Marseillaise," sung by girls of the secondary schools of Paris to the band of the Republican Guard. At the Sorbonne the British delegates took a very intimate part in celebrating with France the tie that binds the two countries through the association of Lister and Pasteur. Here is the great picture showing Lister's tribute to Pasteur, and here in the presence of the British Ambassador and delegates in their academical robes, was unveiled the marble tablet erected by the University of Paris to commemorate the fraternal embrace of the two scientists, symbolic of the friendships of the two peoples.

On the Saturday thoughts of the earlier days of Pasteur at Paris were called up by a visit to the Ecole Normale and of the fame of his later years there by a reception given by the Municipality of Paris. A commemorative plaque was unveiled on the house in which he lived when a student at the Ecole Normale, and in the little room in the college which later served as his modest laboratory, now decorated with a fresco portraying him at work, one seemed to sense the enthusiasm with which the young experimenter carried on his epoch-making work on the tartrates and the excitement when he found his views on optical activity and crystalline form confirmed by the polariscope. In this work was the germ of all his future studies. The minuteness of experimentation was typical of the care which was the basis of his far-reaching discoveries on fermentation and disease: discoveries which made it possible to associate with the centenary of one man advances in medicine, biology and chemistry contributed to by many hands but built on the foundations he so surely laid. The splendours of the reception at the Hôtel de Ville were worthy of so great a city. Paris, in common with Strasbourg and many a smaller town visited by the President during this memorable week, rendered its tribute to the devoted work which so closely touched the well-being of their hospitals and their public health. So far as Paris was concerned, the commemoration ceremonies were now over, but the hospitality of the French Government was far from exhausted. Sunday was a day of rest for some, but not for a large number of ladies at Paris who carried the war in the streets of the city and, by selling "Laboratory Day" emblems, gained 500,000 francs for the Pasteur Institute. The day was closed by a grand gala performance at the Opéra and followed on Monday and Tuesday by a banquet to 1200 guests at Versailles and a visit to the Palace of Chantilly organised by the Institute of France. Dining in the great hall at Versailles, surrounded by the gigantic battle pictures, and wandering in the park, where the Grands Eaux delighted the eye, or among the ghosts of Marie Antoinette's Court at Trianon, one felt how out of place the modern man in black is among the golden galleries decorated for the Grand Monarque and his glittering court. Here another bust to Pasteur was unveiled, placed, perhaps rather incongruously, in the Galerie des Glaces among the glories of a departed age, but typifying the dawn of a better if more drab age of health. Chantilly was more intimate, the pleasures of the charming park being added to by the echoing calls of the French horn and completed by a visit to the Museum and Picture Gallery.

Carried by special trains to Strasbourg, the delegates assisted at what the French called the Apotheosis of Pasteur at the City and University of Strasbourg, where several years of his busy life were spent. A permanent museum built in connexion with the Institute of Bacteriology to show every phase of Pasteur's work, and an international exhibition, unfortunately still incomplete, connected with such industries as have benefited by his discoveries, were opened by the President of the Republic. The evening was made memorable by a reception at the Town Hall. The great Place de Broglie, gay with festoons of blue, white and red lamps, was thronged with people calling for speeches from Millerand and Poincaré from the balcony. The playing and singing of the "Marseillaise" and the torchlight parade of soldiers marked with enthusiasm the climax and concluding scenes of a memorable week—memorable to France politically, showing the unity of Alsace and itself and the friendship of the nations who had sent scientific delegates, and an indelible memory to the delegates who had come so far to honour France in her great chemist. They had met old friends and made many new ones, and would return impressed with a sense of the confidence of the people in a future bright with hopes of health and prosperity founded on scientific progress.

The Chair of Agricultural Chemistry and Bacteriology in the University of Göttingen has been offered to Dr. A. Kipple.

A METHOD OF MAKING NON-FINGERY COKE FROM BITUMINOUS COALS HIGH IN VOLATILE MATTER

By KOTARO SHIMOMURA

Practically all the coals in Japan are high in volatile matter, ranging from 38 to 40 per cent., and when heated in coke ovens give what the Americans call "fingery" coke. The usual method to remedy the ill effect is to mix with anthracitic coals in order to lessen the percentage of volatile matter. It has been found that by-product coke-ovens have a tendency to increase the density at the expense of augmenting the fingery condition, an effect rendered more conspicuous after stamping. For such coals, beehive ovens give better results, owing, it is supposed, partly to slower heating and partly to the tar running down and filling up the incipient cleavages. Experience showed that with such coals the by-product ovens gave a product no better than gas coke.

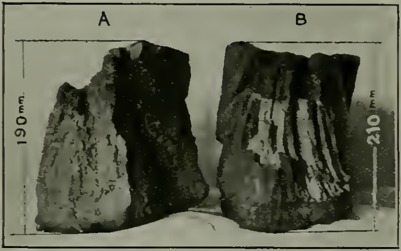

Fig. 1

In 1908 the writer was granted a patent (Jap. pat. 13,583) for his method of making metallurgical coke with bituminous coals, which being translated into English runs thus:—

Our coals having mostly a high percentage of volatile matter, the coke produced from them contains the lines of cleavage so closely situated that it easily shatters to pieces, which renders it worthless for metallurgical purposes. Generally speaking, in order to produce good coke out of such coals it is a common practice to mix them with coals of low percentage of volatile matter, especially with coals of an anthracitic nature. But the resources of such coals in our country are so limited that dependence on the anthracites makes the manufacture of coke a very precarious business.

The object of my invention is to make the coke manufacturer independent of anthracites or coals of low volatile matter, in the production of non-fingery coke. The method of attaining this object I will explain hereunder.

A coal of high volatile matter is charged into a suitable retort or oven, and distilled till it parts with a certain portion of volatile matter, when it is quenched. To accomplish this beehive ovens are unsuitable; a special apparatus heated with gas from the outside gives the best results. The proper degree of heating depends upon the nature of the coals used; but generally the temperature most suitable lies between 300° and 600° C. The object in view is to leave in the coal an amount of volatile matter ranging from 15 to 25 per cent., depending on the nature of coal. The amount of volatile matter to be left is to be decided by actual experiments with the particular coals employed. The product thus obtained is quenched in water, and if necessary, ground and washed free from foreign matter. It is then mixed with the bituminous coals in the proportion of 20 to 35 per cent. of the former, and 80 to 65 per cent. of the latter. With good caking coals it is possible to mix the product to the amount of 35 per cent. The mixture is then charged into coke ovens and heated at the usual temperature, ranging from 1000° C. to 1400° C. If it is desired to obtain coke of high density, it is recommended to heat it at a temperature as high as the bricks of the oven permit; when it is desired to obtain coke of comparatively porous character, a temperature of about 1000° C. is most suitable.

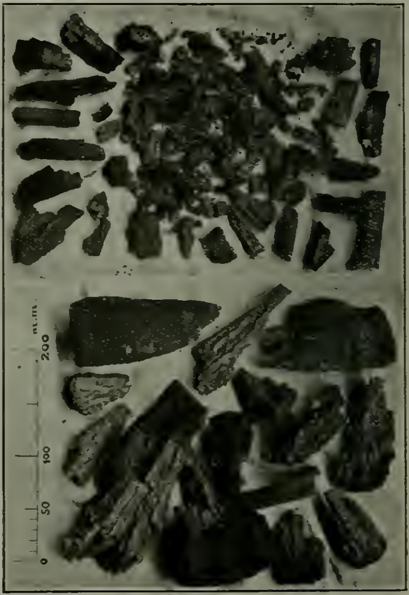

Fig. 2

The sphere of my invention for which I claim the right of patent is stated as follows:—

(1) The method of making non-fingery coke out of a bituminous coal, without using natural coals of low volatile matter; according to which a certain coal is heated at a temperature between about 300° C. and about 600° C., so as to leave from 15 to 25 per cent. of volatile matter in the coal; this coal is mixed with the unheated coal in the proportion of 20 to 35 per cent. of the heated coal, and 80 to 65 per cent. of the unheated coal, and the mixture is heated at a temperature between 1000° C. and 1400° C. (2) The method of making non-fingery coke out of bituminous coals without using natural coals low in volatile matter; according to which a coal or a mixture of coals is heated as described under (1), and this coal or the mixture of coals thus heated is mixed with the unheated coal or the mixture of unheated coals in the proportion given in the method (1), and heated in the same way.

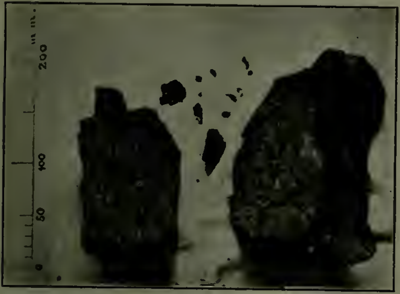

Fig. 3

(3) The method of making non-fingery coke by using coals which had been heated at a suitable temperature to supply the deficiency of the natural coals of low volatile matter; according to which, when the natural coal of low volatile matter is insufficient, that is, when, say, 20 to 35 per cent. is wanting, the balance required is supplied by coal or coals whose volatile matter had been artificially expelled, as described in (1) and (2).

The Japanese Government, after thorough investigation of the patented process, and of the actual working of the plant at Osaka, in view of the paramount importance of the process, has recently granted another term of protection from 1923 to 1930. Fifteen years ago the fuel question had not assumed the importance it has taken to-day. Connected with the recovery of low-temperature carbonisation oils the method of utilising the residue for such a purpose as the manufacture of metallurgical coke is considered by some to be entitled to sympathetic encouragement.

Certain characters of the semi-coal are essential for the successful attainment of the object, among which the amount of volatile matter left is one of great importance. When the semi-coal contains less than 15 per cent. volatile matter, the coke produced will be found to be inferior in quality. When common coke breeze is used, although the fingery condition disappears, the mass obtained is not compact, the particles being loosely cemented together. Another essential qualification is that the particles of semi-coal must have very nearly the same amount of volatile matter. Hence for the practical working on a large scale, the difficulties encountered were found to be somewhat serious. In carrying out the process, an apparatus was designed, bearing in mind the following points:—

(1) Brisk agitation is necessary to prevent the coal from caking in large pieces.

(2) The apparatus is to be provided with the fewest projections or appendages possible, consistent with its proper working, in order to prevent semi-coal from hanging on and accumulating.

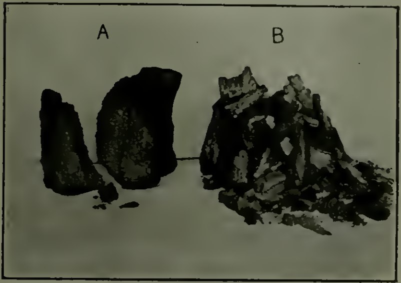

Fig. 4

(3) For evident economic purposes, the operations of feeding and of discharging must be continuous, for which object the agitating and conveying must go together.

(4) Easy access to all the parts of the inside of the retort throughout its entire length without stopping the working is necessary for inspecting and cleaning when needed.

(5) The possibility of easy regulation to suit different kinds of coal. The apparatus, designed so as to meet all the above requirements, was found to work quite smoothly, and the writer is satisfied with the successful practical working on a large scale.

It is quite surprising what a great difference it makes when this semi-coal is used for mixing. It was found that as the quantity of volatile matter decreases below 15 per cent., the compactness of coke decreases, though the cleavages are absent. The photographs in the text illustrate the great difference between the coke made from the mixture, and that from the straight coal.

The coal used for the specimens in the photographs is "Koyaké," one of the two best caking coals found in Japan. It contains 6–7 per cent. of ash, 0·8 per cent. of sulphur and 38–39 per cent. of volatile matter. If heated in beehive ovens, it gives a tolerably good coke, but in by-product ovens its fingery characteristics are quite conspicuous. Fig. 1 is a photograph of the two samples of coke; A is the coke made from the coal mixed with the semi-coal, containing 15–17 per cent. of volatile matter, and B that from the coal unmixed. These are fair samples obtained by coking in Semet-Solvay ovens under equal conditions of heat and duration. The same pieces after being photographed were dropped from a height of 12 feet upon a concrete pavement, and their condition after falling is shown in Fig. 2 and Fig. 3, the photographs being taken from above. Fig. 2 represents the broken pieces of B arranged by size, and Fig. 3, those of A. Fig. 4 is the photograph of the broken pieces of the respective samples, the shattered pieces of B being here shown piled one upon another, and the divided pieces of A standing up. This striking difference is noticed to almost the same extent when the finished products pushed out from the ovens fall on the coke side pavement. In point of hardness, compactness and size of pieces, the coke made from the mixture is found to be equal to the best grade of European coke.

MEXICAN PETROLEUM OUTPUT IN 1922

The petroleum industry in Mexico faced a most critical period in 1922, and the low demand left stocks estimated to be sufficient to supply the world for about six months of 1923. Production started in 1922 with the highest figures yet registered for one month, the output in January reaching 20,641,862 barrels. Afterwards there was a slight decline, but production was maintained almost constant until June, when the output was not less than 179,265,000 barrels, which, although lower than the figure for 1921 (193,397,587 barrels), is still very high. Mexico thus continues to occupy the second place among the petroleum-producing countries, the United States coming first. Up to September, 1922, the latter country had under exploitation 275,000 oil wells, which yielded 1,503,000 barrels daily, an average production of 5·5 barrels per well daily. In Mexico, during the same period, there were in exploitation only 274 wells, which gave an average daily output of 1358 barrels each. This shows that even though some of the large Mexican deposits are rapidly declining, the output was nearly 300 times larger than that of the United States—a fact which not only shows the great importance of Mexico's contribution to the world's oil supply at present, but may also prove of greater significance in the future.

FORTHCOMING EVENTS

June 12. University of London, St. Bartholomew's Hospital Medical College, West Smithfield, E.C. 1, at 5 p.m. "Tropical Hygiene," by Dr. A. Balfour, C.B. Also on June 14, 19 and 21.

June 12 to 14. Institution of Mining Engineers. General Meeting, Royal Technical College, George Street, Glasgow.

June 14. Chemical Society, Burlington House, Piccadilly, W. 1, at 8.30 p.m. "Les Gazes Rares des Sources Thermales, des Grisous et Autres Gazes Naturels," by Prof. Moureu.

June 15. The Royal Institution of Great Britain, 21, Albemarle Street, Piccadilly, W. 1, at 9 p.m. "Life History of an Alpha Particle from Radium," by Sir E. Rutherford, LL.D., D.Sc., F.R.S.

June 16. The Royal Institution of Great Britain, at 3 p.m. "Atomic Projectiles and their Properties," by Sir E. Rutherford.

June 16. Society of Chemical Industry, *Edinburgh and East of Scotland Section.* Excursion to Melrose and Abbotsford, leaving Edinburgh at 1.30 p.m.

June 16 to 20. Meeting of the Union Internationale de la Chimie Pure et Appliquée at Cambridge.

June 20 to 23. Society of Chemical Industry. Annual meeting at Cambridge.

June 28. The Institution of Electrical Engineers. The annual conversazione will be held at the Natural History Museum, South Kensington, S.W., at 8.30 p.m.

SULPHUR INDUSTRY IN CHILE

Chile possesses important sulphur deposits scattered along the chain of the Andes close to the numerous volcanoes of that region. Some deposits, however, are situated at such a high altitude that work is impossible except during summer; others cannot be easily worked because they are in volcanic regions; and a hindrance to the general development is the absence of roads. The most important deposits which have been developed and worked are in the northern zone between the provinces of Tacna and Antofagasta. Production gradually increased up to 1920 owing to the rising demand for sulphur for making powder for the nitrate mines, to the progress in Chilean chemical industry and to increased exportation. The output, however, fell from 13,340 tons in 1920 to 9670 t. in 1921, largely owing to decreased exportation. Future development of the industry depends on progress in Chile's chemical industry and on the provision of improved methods of extraction and transport facilities.—(*U.S. Comm. Rep., May* 7, 1923.)

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

THE MINING EXHIBITION which is being held at the Agricultural Hall provides an opportunity for those who desire to see the latest developments in this industry. I spent an interesting hour looking at the exhibits which have been got together from France, Belgium, Holland, Mexico, Rumania and various other parts of the earth. The Department of Scientific and Industrial Research, the Imperial Mineral Resources Bureau, the Imperial Institute, and the Imperial College of Science and Technology seemed to have vied with each other in producing a number of most interesting exhibits to represent Great Britain's share. I think the most interesting feature is the number of Conferences which have been arranged to take place. There has always been some doubt as to the possibility of getting Conferences of this kind attended by the right people. I see that, apart from those Conferences which relate directly to Mining and Metallurgy, two lectures are to be given, one by Mr. E. I. Lewis, on "The Importance of Fine Chemicals in Industry," and the other by Mr. Edmund White, on "The Purity of Chemical Reagents." These are to be delivered on June 14th, and on the same day there will be a reception for the Société de Chimie Industrielle, and the Union Internationale de la Chimie Pure et Appliquée.

TWO INTERESTING CASES are to come before the Referee under the Safeguarding of Industries Act. It is some time since the last case was heard. The two new cases deal respectively with Formaldehyde and Rochelle Salt, and I suppose we shall witness the usual spectacle of those who desire to import the foreign chemicals bringing forward a number of witnesses who are prepared to give it as their opinion that neither of these chemicals are synthetic organic chemicals or fine chemicals, and on the other side there will be an equal number who will go into the witness chair and endeavour to prove the contrary. I rather thought, as the interval since the last case became longer and longer, that we had had the last of these somewhat dreary proceedings. Apparently it is not so, and we shall soon be back at the old game again. The Formaldehyde case will be heard in the Conference Room of the Board of Trade, on June 15, at 10 a.m.

I THOUGHT PROFESSOR HELE-SHAW'S paper on Monday was very good. He described his stream-line filter to the London Section of our Society and he did this in a manner which was equally pleasing to his audience and himself. He is really quite a highbrow man, full of weird learning of the most abstruse and terrifying kind, but he talked to us with the simplicity—well assumed—of a man with just enough skill to make a few small models and with plenty of spare time which he was not going to misuse by spending on chemical and other problems far beyond his small intellect and limited energy. His pose of handing to the chemists a little toy with which they could do their own dirty work of filtration was maintained until the end and his airy way of offering a few of these filters to chemists on the footing that they would tell him the cases in which they might be useful was a delicate piece of leg-pulling. I cannot remember a more ingenious piece of apparatus nor an explanation framed in such easy and elementary terms. Even an editor could have understood it! The filter is going to be an important instrument in the hands of most chemists and will solve a very large number of difficult problems and in spite of Dr. Hele-Shaw's kind words about sundry competing apparatus it may become an important competitor of some of these. When he next doth read a screed, may I be there to hear!

AT THIS SEASON of the year I have forgotten what the young man's fancy turns to, but the chemist of maturer age has his attention directed towards dinners. On Wednesday this week the Anglo-Batavian Society entertains Professor H. A. Lorentz to dinner in recognition of his work on the refraction of light, his calculation of the respective merits of various formulæ defining it compiled by Gladstone and Dale, Landolt, and L. V. Lorenz, and his investigation of the Zeeman effect. On the 14th the Chemical Club entertains Professor Moureu and his French colleagues to dinner; on the 15th Mr. C. S. Garland, M.P., and some of his colleagues in the House of Commons will entertain the French visitors, who will then be in London. I am told that Lord and Lady Inverforth will be present and some others who are glad to take an opportunity of showing our visitors how welcome they are. After this a number of banquets are arranged at Cambridge, at Northwich and elsewhere. Thick and fast they come at last and more and more and more. I cannot remember what poet wrote this line, but it seems quite familiar.

THE FULLERIAN PROFESSORSHIP of Chemistry at the Royal Institution has, I hear, been filled by the appointment of Sir William Bragg. Sir William has had a very wide experience, having held professorships at Adelaide, Leeds and London, and his research work, chiefly on radio-activity, has brought him recognition in the shape of numerous honorary degrees. I look forward to more of his interesting discourses in the lecture-theatre of the Royal Institution.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL MEETING

CAMBRIDGE. JUNE 20 TO 23, 1923

Addresses. The title of the President's address to be delivered on Thursday, June 21, is "Chemistry and Industry," and that of Dr. Charles Carpenter's address on the following day is "The Evolution of a Chemical Industry."

Accommodation of Members in Colleges. Accommodation will be available for men in various colleges from the afternoon of Wednesday, June 20, to the afternoon of Saturday, June 23. Members who arrive on Wednesday will be charged an inclusive fee of £3, those arriving on Thursday an inclusive fee of £2. These fees include the use of a set of rooms (bedroom and sitting-room), attendance, gratuities to college servants and the following meals: *Wednesday, June* 20.—Tea (if required) and dinner. *Thursday, June* 21.—Breakfast, lunch and dinner. *Friday, June* 22.—Breakfast, lunch and dinner (if required). *Saturday, June* 23.—Breakfast, and lunch (if required). Members will usually take their breakfasts in their rooms. Luncheon and dinner will be served in the halls of colleges. On Thursday and Friday tea will be served at the Vice-Chancellor's reception, and at the Garden Party at Sidney Sussex College respectively. Members who arrive before five o'clock on Wednesday, and who will require tea, are requested to give notice to that effect on a form to be supplied. There will be no extra charge. Members unable to attend the Annual Dinner of the Society on Friday, and desirous of dining in college that evening, may do so without extra charge by giving notice to that effect on the form above referred to. Members who do not make the trip to Ely, and who require luncheon before leaving Cambridge on Saturday, may obtain it in college on that day without extra charge.

It is important to note that alcoholic drinks are not included in the charges specified above, and members requiring such drinks with their meals must sign a chit presented by the waiter at the time of ordering. Payment for such must be made by members at the office of the Society at the Arts School, Bene't Street, on Saturday, before departure. It is the wish of the college authorities that no money shall change hands at table, and it is hoped that members will kindly co-operate in order that this scheme of payment may be a success.

To the list of colleges offering accommodation given on page 491 of *Chemistry and Industry* of 18th May, Corpus Christi is to be added. As previously stated, men requiring accommodation should communicate with Mr. J. E. G. Harris, the University Chemical Laboratory, Downing Street, Cambridge, who will supply any further information and forward a form to be filled up by the member.

Hotel Accommodation. There are still rooms available at The Bull and at The Blue Boar, but the other hotels are more or less full. There is good accommodation to be obtained in boarding houses (college rooms) should the supply of hotel rooms be exhausted.

The Smoking Concert on June 20 will be held in the dining room of the University Arms Hotel.

Group Photograph. A photograph of the members will be taken at the close of the Annual General Meeting on Thursday, June 21.

Tickets. Tickets for the Smoking Concert, the Reception and Dance, the Annual Dinner, and the excursion to Ely with lunch will be handed to members who have paid the inclusive fee when they register at the office in the Arts School, Bene't Street, Cambridge.

Guide to Cambridge. A copy of the illustrated Guide to Cambridge has been forwarded to each member who has purchased his tickets.

News. Further information will be published from week to week in *Chemistry and Industry.*

Members intending to be present at the meetings are asked to send in their forms with the appropriate remittance as soon as possible, if they have not already done so, in order that adequate arrangements may be made for them.

Nominations to Council.—The following have been nominated under By-law 24 to fill four vacancies among the ordinary members of Council: Professor P. Phillips Bedson, Dr. R. T. Colgate, Mr. William Cullen, Professor A. R. Ling, Dr. Joseph Reilly, and Dr. E. W. Smith.

A ballot list has been posted to every member entitled to vote.

J. P. Longstaff,
General Secretary

ADVANCE PROOFS OF PAPERS

Authors of papers which are to be read before local sections or groups, may in some cases desire to have a few advance proofs for distribution among those likely to make useful contributions to the discussion. Any author who requires such advance proofs is requested to hand the manuscript of his paper to the Local Secretary so that it may reach the Editor at least *one month* before the date of the meeting at which it is to be read, in order to allow sufficient time for it to be considered by the Publications Committee and, if approved, set up in type.

PHOTOGRAVURE OF THE PRESIDENT

A photogravure of the President of the Society of Chemical Industry, E. Frankland Armstrong, D.Sc., Ph.D., F.R.S., is sent out with the issue of the Society's *Journal* for June 8 curt.

NEWS FROM THE SECTIONS

LONDON SECTION

On June 4 a meeting was held in the Rooms of the Chemical Society, Burlington House, to hear a paper on "The Stream-Line Filter," by Dr. Hele-Shaw, F.R.S. Mr. E. V. Evans presided.

In presenting his paper, the author said that he had found in the course of experiments with thin films, that it was possible not only to separate the very finest matter in suspension from the fluid, but apparently even to separate two fluids of different densities if the film were sufficiently attenuated. To do this a fibrous or textile material was used that was impervious to the action of the fluid. A form of laboratory filter was demonstrated in which waterproof paper was used; he had found this paper superior to any other kind of paper tested, as it was impervious, not only to water, but even to boiling water, paraffin, oil, petrol, etc. A filter capable of dealing with water at the rate of 150 gallons per hour and a few laboratory filters were demonstrated. The filters were working on coloured water, paraffin, and oil. The coloured water was deprived of its colour in the filter, as would be the case with peat water, an operation which ordinary filter paper could not effect. Paraffin used for cleaning machinery and which was full of suspended dirt was made clear and transparent and of a light straw colour very similar to that of the original material, whereas on passing through ordinary filter paper it was a reddish colour. The filter was not merely experimental, but designed for commercial use as it was able to treat large quantities of fluid within a very moderate bulk and at a moderate cost and weight. Very severe filtration could be effected, involving very attenuated films and therefore high pressure. The process of filtration was continuous and the residue could be removed without opening the filter, whilst the material used did not seem to deteriorate and so far had not required replacing after severe usage. The capacity of the filter depended, *inter alia*, on the viscosity of the fluid, the dimensions of the apertures through which filtration took place, the area of filtering surface, and the amount of hydraulic pressure which could safely be applied to effect the operation.

The essential points of the stream-line filter were the use of one or more packs of impervious material, preferably paper on account of its lightness and cheapness, each pack being held between two ends called "press heads," which enabled the pressure to be controlled according to the filtration required. With a view to economy, the sheets in the pack were rectangular in form, and to obtain as large a filter surface as possible for what could be called *edge* filtration as opposed to *surface* filtration, each sheet was perforated with an identical number of holes in such a way that the holes lay in alternate rows of large and small holes. When the sheets were put together in a pack (the filter shown contained 4000—5000 sheets), the holes formed tubes. If into one row of tubes the liquid to be filtered was forced under pressure, and the opposite ends of the tubes were closed, the liquid could only escape through the interstices of the sheets, leaving behind the suspended matter in the "inlet" tubes, and passing down the smaller or outlet tubes.

It was obvious that the area of filtration was represented by the area of the inner surface of the larger cylindrical tubes and that was why these tubes were made larger. The smaller tubes were quite sufficient to discharge the filtrate. After a time the larger tubes became more or less filled with residue, and could be washed out after opening the filter. If necessary, the process could be reversed, the smaller tubes becoming the pressure tubes and the filtered material then being washed away. As the operation of washing out the residue from the inlet tubes required at most a few seconds, it was possible to have a large number of packs in which a small percentage, probably not more than 1 per cent., was put out of action at a time. Filtration could thus be made continuous, if to the necessary dimensions required for full filtration a very small addition was made, even a fraction of 1 per cent. of the required capacity of the filter, the same mechanism which operated the pump opening and closing alternately the discharge taps for the residue.

Assuming that there were 50 pairs of holes in a sheet and 5000 sheets in the filter, there would be a quarter of a million large inlet and small outlet holes in a pack, the one shown being 2 ft. 6 in. high by 1 ft. square. By putting, say, six packs in four rows one above the other, the whole occupying less than 100 cb. ft., there would be 6 million units. The filter demonstrated discharged at the rate of 150 gallons per hour, so that 100 cb. ft. represented the volume of a filter filtering 3600 gallons per hour.

The pressure required depended entirely on the fineness of filtration and the viscosity of the fluid. If the liquid were water from which colouring matter and possibly even bacteria had to be removed, 100 lb. would be reasonable pressure and less than 4 h.p. would be required for pumping, etc.

In the ensuing discussion, Prof. J. W. Hinchley observed that although the stream-line filter would not replace entirely any existing filters, it would probably prove a most valuable adjunct and would find a great variety of new uses. Mr. J. A. Reavell also pointed out the wide ranges of uses that would be suggested for the new filter, uses that were discussed more in detail by Dr. W. R. Ormandy, Mr. F. H. Carr, Mr. Julian Baker, Mr. W. McNab and others.

MEETINGS OF OTHER SOCIETIES

THE FARADAY SOCIETY

The long postponed symposium on "The Physical Chemistry of the Photographic Process" was held at the Institute of Electrical Engineers on May 28 with Sir R. Robertson in the chair. Amongst the numerous visitors, many of whom had travelled far to be present, were Prof. W. D. Bancroft, of Cornell University, Profs. Luther and Goldberg, of Dresden, Monsieur Clerc, of Paris, and Dr. Errera, of Brussels.

Prof. Bancroft in his opening brief introductory address, divided his remarks into three sub-divisions: The Emulsion, the Latent Image, and Development. A theory of emulsion making, he said, is lacking, and must remain so until the actual makers of the emulsions are prepared to divulge some of their jealously-guarded secrets, and give outside scientific investigators sufficient data to form a working hypothesis and so in this way open up a new point of view. Passing on to plate sensitivity, he showed by eliminating in turn all other possibilities that he was driven to conclude that the sensitivity of a ripened emulsion was due to a complex of silver halide, gelatin, and water. He suggested that the experimental manufacture of an emulsion by dispersing pure silver halide in gelatin would probably give us information as to whether in the complex the gelatin was actually entangled in the crystal lattice. Why gelatin still remained the best sensitising agent for silver halide was still an open question, and little seemed known on this point. Considering grain sensitivity, he dealt with the two main hypotheses put forward to explain it. He disposed of Silberstein's "light dart" theory by quoting W. Clark's work carried out at the British Photographic Research Association Laboratories on the action of sodium arsenite on a photographic plate, in which Clark showed that this action duplicates that of light. He was, therefore, driven to accept the hypothesis that the grains upon a photographic plate made with a ripened emulsion exhibited a range of sensitivity. He considered the question of the formation of the latent image quite settled. The latent image consisted of silver adsorbed by the silver halide, the explanation put forward by Carey Lea many years ago, and afterwards confirmed by the voluminous work of Lüppo-Cramer. The possibility of the formation of a subhalide was dismissed, since no subhalides could be isolated, and the latent image behaved as a phase of continuous varying composition.

In discussing the theory of development, Prof. Bancroft said that no present-day theory faced all the facts. A developer was necessarily a reducing agent, yet all reducing agents were not developers. Reducing agents could be divided into three classes respecting their action upon the photographic plate; the first class, exemplified by formaldehyde, reduced the whole of the silver halide, *i.e.*, both the exposed and unexposed portions of the plate; the second class comprised the ordinary developers, which produced negatives in the usual way, and the third class those substances that produced positives even with short exposures of the plate. It is, therefore, a question of reaction velocity; if the latent image was more rapidly reduced than the unexposed silver halide, a negative was produced; if the latent image, and the unexposed bromide were reduced with equal velocities, we had the conditions of the action of the first class of reducing agents, and finally, if the unexposed halide were more rapidly reduced than the exposed halide, a positive resulted. He postulated, therefore, the existence of selective adsorption of the reducing agent by the exposed and unexposed silver halide. If this adsorption was greater for the exposed than for the unexposed silver bromide, the former would develop more rapidly than the latter, and a negative be produced. The other cases could be explained similarly.

If this explanation was true, selective peptisation should take place, and it should be possible to remove the latent image by washing a plate in a solution of a developer *without alkali*. Preliminary experiments made in the Cornell laboratories had indicated that this was possible: an exposed Seed 23 plate had the whole of the latent image removed by washing with a non-alkaline metol solution.

The subject was now divided into four sections.

Dr. Slater Price, of the British Photographic Research Association, opened Section I with a paper on "Gelatin and Collodion." He pointed out that nothing was known about the sensitising action of gelatin on silver halide, but that many of the physical properties of gelatin had been correlated with the practice of photography.

Dr. Chr. Winther's (Copenhagen) paper, showing no change in the solubility of silver bromide in the presence of gelatin and ammonium bromide, was communicated by Sir R. Robertson. This paper was supplemented by Prof. J. W. McBain, who gave similar details of the solubility of silver chloride, but also added that freshly precipitated silver chloride in the presence of a colloid was approximately 20 per cent. more soluble than when, after a few hours, it had reached a stable state.

Dr. F. C. Toy, of the British Photographic Research Association, opened Section II, and chiefly devoted his attention to the inadequacies of Silberstein's quanta theory of photographic action. He showed from the results of his own investigations that this theory would not in its present form explain the experimental facts; he himself had been forced to assume the presence of some foreign matter on the surface, or inside the grain, to account for the grain sensitivity, the production of which probably took place during the manufacture of the emulsion. This foreign matter after exposure produced development centres on the grains, and the experimental relation between the number of centres, and the wave length of the light used, though contradictory to Silberstein's theory, was that which one would expect when allowance was made for the light absorption of the grains.

Mr. W. Clark, of the British Photographic Research Association, again emphasised the heterogeneity of the grain in the photographic emulsion. He showed that by treatment with dilute chromic acid, the speed of a previously exposed plate was reduced to a low minimum. He claimed to have removed the specially sensitive spots from the halide grain by the chromic acid treatment; moreover, the accompanying increase in the gamma of the treated plate suggested that this treatment had made the sensitivities of the grains more uniform by the removal of the most sensitive points.

Dr. Errera, Brussels, contributed a paper on the sensitivity of asphalt, and Mr. Crowther, of the Kodak Co., gave a brief summary of a paper by E. P. Sheppard, F. A. Elliot, and S. S. Sweet, of the Kodak Research Laboratory, on the photographic chemistry of gelatin.

After the tea interval, it was made clear that the majority of the speakers were antagonistic to Silberstein's quanta theory in its present form. The subject was perhaps best summed up by Prof. Porter, who said that the light-dart theory as it stands was quite impossible, because it had been proved that spatially discrete quanta in the free ether did not exist. It was necessary though to utter a word of warning. If the developability of the grain depended upon electron emission, then some form of the quanta theory would be necessary, but not as regards the *incident* light.

Mr. Bloch, Ilford, opened Section III with a discussion of the methods of plate sensitometry. He pointed out the complete inadequacies of present-day methods of expressing sensitometric properties of plates, and showed that if the object for which a plate was to be used were specified a knowledge of the characteristic curve gave considerable help, otherwise no satisfactory method had been devised for expressing the sensitometric properties of a plate.

Mr. T. Thorne Baker, Imperial Plate Co., considered the characteristic curves produced with filtered X-ray radiation, and showed that they closely resembled the ordinary characteristic curve, but the curve produced with unfiltered heterogeneous X-ray radiations practically consisted of only a long "foot," no straight line portion being apparent.

The meeting then adjourned to dinner, which was held at the Hotel Cecil. After dinner, Prof. Luther continued Section III with a paper on the characteristic curve. He has been able to obtain an equation for the foot of the characteristic curve, after the examination of over 700 typical characteristic curves, and hence to give an explanation of the Watkins system of factorial development.

Prof. Goldberg, of Dresden, gave a summary of the uses of his wedge in photographic investigations, and also a short demonstration of the manufacture of such a wedge. He also showed a new method of measuring halation.

Mr. Pledge, Kodak Co., read a paper by L. A. Jones, of the Kodak Research Laboratory, on some new instruments used in photographic sensitometry. The paper clearly gave a short description of some of the ingenious methods used by the Kodak research workers.

With the time limit drawing near, the meeting concluded with M. Clerc, Paris, reading Lumière and Seyewetz's paper on toning of sulphide prints, in which it was shown that the toned image of a red gold-toned sulphide print probably contained a double sulphide of silver and gold.

It was, perhaps, unfortunate that such a large number of papers had to be dealt with in such a short time. The limited period both for reading of papers and the discussions left a feeling of incompleteness and rush, which would have certainly been emphasised but for the admirable chairmanship of Sir Robert Robertson. It is noteworthy that, although fundamental investigations on this subject were commenced only a few years ago in this country, numerous references were made to this comparatively recent work.

PERSONALIA

On the occasion of the meeting of the International Union for Pure and Applied Chemistry at Cambridge the degree of D.Sc., *honoris causa*, will be conferred upon Prof. W. D. Bancroft, of Cornell University; Prof. E. J. Cohen, of the University of Utrecht; Monsieur A. Haller, President of the Académie des Sciences; Prof. C. Moureu, of the Collège de France; Prof. R. Nasini, of the University of Pisa; Prof. A. Pictet, of the University of Geneva; and Prof. F. Swarts, of the University of Ghent.

Sir William Bragg has been elected Fullerian Professor of Chemistry in the Royal Institution, Director of the Laboratory, Superintendent of the House and Director of the Davy-Faraday Research Laboratory, in succession to the late Sir James Dewar.

* * *

The deaths are announced from Germany of Prof. H. Goldschmidt, a well-known German chemist and the discoverer of thermite; of Prof. W. Roser, director of Meister, Lucius, und Bruning; and of Prof. M. Gary, an authority on the testing of building materials.

CORRESPONDENCE

THE EXISTENCE OF AMMONIUM IN SOLUTION

Sir,—Prof. R. M. Caven, in support of his point of view, quotes from Holleman's Text Book (*Chemistry and Industry*, 1923, p. 449). In this quotation occurs the statement: "We should expect ammonium hydroxide, so far as it is formed, to be extensively ionised, like strong bases, inasmuch as the ammonium salts of strong acids such as the chloride and nitrate react neutral."

Now for N/100 ammonium chloride solution C_H is about $0{\cdot}2 \times 10^{-5}$, which is acid to phenolphthalein and even to litmus. Moreover, it shows that hydrolysis has taken place, a point which is quite obscured by the phrase "reacts neutral." Is it not time the ambiguous use of the word "neutral" was abandoned, unless the indicator used is specified? And is it fair to draw conclusions such as the above, when a solution of ammonium chloride is acid to an indicator with which sodium chloride gives a neutral reaction?

Prof. Caven is, I take it, only using the reference (of which I have only quoted a portion), to show that the order of increasing alkalinity, chloride, carbonate, cyanide, is the same both for salts of ammonium and the alkali metals, and, of course, this is true whatever indicator is used—even for one to which ammonium chloride "reacts neutral"!—I am, Sir, etc.,

"LUCIFER" ON "CALORIFER"

Sir,—Calorifer's oracular "surface criticism" of me and my proceedings, in your issue of May 25 last, leaves my withers unwrung. I suppose it is merely his way of brightening cricket, and we will accept it as such. But surely it is a case of Satan denouncing sin when, immediately after reproving my use of the word "activated," he proceeded to call steam by what I can only describe as "that horrid and un-English word" *hydrone*, which he seems to have invented for it. For such a glaring inconsistency he deserves to be spitted between two of my radiophragms at their fullest incandescence.

I am sorry that apparently he did not enjoy my Royal Institution discourse; but it is impossible to satisfy everybody, and he who tries to do so usually gets nowhere, and often ends by being called a fool for his pains. Perhaps he would have been better pleased had I made out a case for the notion that carbon monoxide never burns except in the presence of dirty hydrone; but I did not. So he laments, in words which somehow have a familiar ring about them, that "it seems impossible for chemists to arrive at any rational conception of chemical change, or to view the phenomena in any consistent comprehensive manner." It seems as though he were croaking from his corner:—

> There ain't no logic, no bloomin' logic in the land,
> Things they 'appen as we cannot understand;
> 'Tis the truth, wot we're gradually arrivin' at,
> 'Arf the time, we dunno wot we're drivin' at,
> For there ain't no logic, no blooming logic in the land.
>
> (*With apologies to Barry Pain for the slight alteration.*)

The only point calling for remark in his rather hasty criticism of our suggestions as to the possible explanation of our discovery of the specific influence of nitrogen in retarding the combustion of carbonic oxide at high pressures is the proof furnished by paragraphs 8 and 9 of his article that he has entirely missed what is surely the cardinal point of our argument. He objects to the view that nitrogen was "activated" in our experiments on the ground that "each of the three kinds of change postulated or possible in the nitrogen molecule, being the effect of heat, should be equally promoted in the isothermic process of combustion with hydrogen."

I thought it had been made perfectly clear, both in our Royal Society paper and in my Royal Institution discourse, that, inasmuch as the experimental results have shown that in hydrogen-air explosions under high initial pressures nitrogen does not play the specific energy-absorbing *rôle* which it undoubtedly does in the corresponding carbon monoxide-air explosions, in the latter it cannot be regarded merely as "an effect of heat," but must be ascribed to some peculiarity of the vibrational energy acquired and manifested by the carbon monoxide during combustion under such conditions.

As a matter of fact, the idea that the observed lag in our experiments may be accounted for by assuming the reversible formation of nitric oxide was considered by us long ago, but discarded in favour of our present views for cogent reasons. Doubtless a part of the "activated" nitrogen primarily formed in our CO-air explosions at high pressures was oxidised in some experiments to nitric oxide, especially when more oxygen was present than sufficed to burn all the carbon monoxide. But an analysis of the actual pressure curves has shown that any such nitric oxide formation was a secondary effect, and that the results as a whole cannot be explained except on the supposition that the lag was primarily due to the "activation" of nitrogen itself. Besides which, even were the "nitric oxide" supposition to be preferable to that of "nitrogen activation" (which it is not), it would still be necessary to explain (*a*) why the said lag was never observed in our hydrogen-air explosions, and (*b*) in the case of our CO-air explosions, why the replacement of a small part only of the carbon-monoxide by its equivalent of hydrogen removed it. To aver (as does Calorifer) that "in hydrogen such action would occur, if at all, to so slight an extent or would be so rapidly reversible that the effect would not be obvious" is surely a mere begging of the question, and no explanation at all. It would seem as though even our critic's logic is not altogether above suspicion.

Our experimental inquiry is still proceeding, and if our critic will possess his soul in patience until some further results of it are published, perhaps I may yet be his Lucifer. For, however hard it may be to illumine the darkness of an old heathen who worships Hydrones, we will not despair of him, but pray that soon he may:

> Accept the blessed Truth, and cast
> His idols all away.

Meanwhile, to those with open minds who wish to judge the evidence for themselves, we would commend a careful study of the results already published in our recent Royal Society memoir. The original photographic pressure records of our experiments, which eloquently speak of nitrogen "activation" by radiation, can be seen by arrangement at South Kensington. Indeed, without a close examination of the actual records, it is hardly possible to appreciate the full weight of the evidence. The subject of gaseous combustion is of such complexity that perhaps only those who are daily in contact with it can realise how dangerous it is to dogmatise, however much they may wish to view it in Calorifer's "consistent comprehensive manner." But if in its pursuit we remain faithful to the scientific method, and employ our theories as tools rather than exalt them into creeds, we may hope in time to get nearer to the truth of things.—I am, Sir, etc.,

William A. Bone

London. June 1, 1923

Note.—With reference to Professor A. J. Allmand's letter of May 25, he is wrong in supposing me to be unaware of Haber's results.

W. A. B.

GASEOUS COMBUSTION

Sir,—With reference to Professor Allmand's and Calorifer's letters on Gaseous Combustion, I should like to inform you that, through Professor Bone's kindness, I have had the opportunity of scrutinising and closely analysing independently the actual pressure-time curves obtained by him and his co-workers (the late Mr. Haward and Messrs. Townend and Newitt), and have come to the conclusions that :—

(*a*) The slowed rate of cooling after attainment of maximum pressure in CO. O_2 and N_2 mixtures at an initial pressure of 50 atmospheres, can in no wise be accounted for on the assumption that it is due to energy released through decomposition of NO formed during combustion.

(*b*) In the combustion of such gaseous mixtures, when exploded at 50 atmospheres, the nitrogen does, in some manner, absorb a considerable part of the energy released by the oxidation of CO to CO_2.

(*c*) Though in all the experiments with such mixtures NO was probably formed in varying small proportions, yet such NO formation was entirely subsidiary to, and occurred only subsequently to, the said peculiar absorption of energy by nitrogen.

(*d*) The delayed rate of cooling after complete combustion, though probably partly due to decomposition of NO, is for much the greater part a result of the energy absorbed by nitrogen during combustion being released.

I have been convinced from my examination of these curves that the interpretation put forward by Professor Bone and his co-workers is entirely warranted by the facts disclosed by the research.

I should like to add that, in my opinion, a detailed examination of the time-pressure curves obtained by Professor Bone and his co-workers is a necessary preliminary to any real criticism or understanding of the results. Reproductions, other than full-scale photographs, do not do justice to the curves, and may, indeed, be actually misleading. I see no reason why nitrogen in the peculiar state where it has absorbed energy as in such explosions should not, for want of a better term, be called "active nitrogen."—I am, Sir, etc.,

RAPID FILTRATION

Sir,—As makers of filter papers we are constantly testing papers for rapidity of filtering. This is done by passing 10 c.c. of barium sulphate precipitate, made under standard conditions, into a paper fitted into an accurately turned funnel, and observing the time taken to pass 5 c.c. of clear liquid. Generally a particular batch gives fairly constant results, say 45 seconds. After long experience we found that one of our chemists got far more constant results with a considerably shorter period than anyone else. For a considerable time we could not account for this, but have recently discovered that it is due to the amount of pressure exerted on the folds necessary to fit the paper into the funnel. If this is done lightly by a series of small pressures between the forefinger and thumb the results are constant and fast. If, however, the fold is drawn between the finger and thumb, using greater pressure, the results are nothing like as uniform, and not nearly as fast. In some cases the time taken is quite double that of the other method.

We should be very interested to know if any of your readers have experienced this. Is it possibly due to the surface tension of the fibres being altered due to excessive handling ?—We are, Sir, etc.

NEWS AND NOTES

UNITED STATES

Bibliography of Colloid Chemistry

The National Research Council has recently issued a bibliography of colloid chemistry in mimeographed form (pp. 135, price $1·00). The author, Dr. H. N. Holmes, of Oberlin College, chairman of the National Research Council Committee on the Chemistry of Colloids, intends this edition to be preliminary to a more comprehensive one. All the 1800 references on 106 topics are classified and many are accompanied by brief comment as an aid in deciding on their relative importance. Among the classified groups are Adsorption, Asphalt, Baking, Biocolloids, Capillary Analysis, Casein, Cellulose and Cellulose Esters, Cements, Clays and Soils, Cleansing, Coagulation, Dialysis, Emulsions, Filtration, Flotation, Foam, Flour, Fogs, Gels, Gelatin, Glass, Glues, Gold, Gums, Hydration, Indicators, Jellies, Lubricants, Milk, Paints, Rubber, Sewage, Silver, Soap, Sulphides, Surface Tension, Tanning, Ultramicroscopy, Viscosity, and Water Proofing.

Potash in 1921

During 1921 only 25,485 short tons of crude potash (166,834 t. in 1920), containing an average of 39·9 per cent. of K_2O, was produced in the United States by 18 companies operating 20 plants. Of this production, 11,907 t. was from natural brine, 3366 t. from cement mills, 1257 t. from blast furnaces and 8955 t. from molasses distilleries, beet-sugar refineries and wood ashes. No production was reported to the U.S. Geological Survey from alunite, silicate rock, kelp or wool washings. During the year, large quantities of German and French potash were purchased at low prices, and this, coupled with the general trade depression, the disorganisation of the fertiliser business and high freight rates, was the cause of the large reduction in production. The Experiment Station of the Bureau of Mines continued its investigation of the extraction of potash from low-grade alunite, but the experimental kelp potash plant of the Bureau of Soils was sold in March, 1922. Imports of kainite, manure salts, muriate and sulphate totalled 212.752 t. and of other potash salts 37,493 t., making a total of 250,245 t. containing 81,017 t. of K_2O.

BRITISH INDIA

Final Forecast of the Sesamum Crop, 1922-23

The final estimates of the sesamum crop in Burma, Madras and Hyderabad are as follows: Burma area 865,000 acres, yield 50,000 tons; Madras area 735,000 acres, yield 97,000 t. (92.000 t. in 1921-22); Hyderabad area 530,000 acres, yield 36,000 t. (37.000 t. in 1921-22). In Madras the average out-turn for the province is 98 per cent. of the normal as against 89 per cent. in 1921. The prospects of the late-sown crop are very fair.—(*Ind. Tr. J., Apr.* 26, 1923).

SOUTH AFRICA

Mineral Output in 1922

Figures are appended showing the production of minerals in South Africa during 1922:—

		Output	Value £
Gold	Fine oz.	7,009.858	32,189,587
Silver	,, ,,	1,117,649	171,324
Diamonds ..	Carats	652,248	2,266,631
Coal	Tons (sold)	9,725,479	3,467,412
Copper ore and concentrates ..	Tons	705	37.036
Metallic tin and tin concentrates	,,	612	59,393
Other base minerals ..	—	—	202.993

The total value of the output was £38,394,376, a decline of £12,871,125 compared with the previous year. Production declined generally, an increase being shown only by silver and corundum. The chief event during the year was the virtual cessation of production on the Witwatersrand gold mines during the first quarter. World-wide depression, strikes in the collieries and the decline of prices of gold were adverse factors. It is hoped that in 1923 costs will fall and that this and the increasing domestic consumption will provide some compensation for the loss of the gold premium.—(*U.S. Comm. Rep., April* 23, 1923.)

GERMANY

Reported Discovery of Potash

It is announced in *The Times* that extensive deposits of potash have been discovered at Klein Kuhren, on the Elb near Dannenburg in Hanover, during test borings for petroleum. Below the potash deposits oil has also been found, but not in appreciable quantity. The boring operations are being continued.

Building Materials

A second, enlarged edition of Prof. B. Haberstroh's "Science of Building Materials" (Baustoffkunde) has appeared in the *Sammlung Göschen*. To cover all the progress which has been made in this field during the last twenty years the work has been divided into three parts. The first deals with natural stones, some woods, and iron, the second with the remaining woods and metals, and the third with earthworks, railways, bridges, etc. The last contains an appendix dealing with recent Ministerial Regulations concerning iron buildings. The most important repairing materials are dealt with and some attention is given to materials used in dwelling-houses, from the point of view of conduction of heat.

GENERAL

Standard Cast-Iron Steam-Jacketed Pans

The British Engineering Standards Association has recently issued a Specification, No. 186, 1923 (pp. 15, price 1s.) for cast-iron and enamelled cast-iron steam-jacketed pans. The designs for these pans were prepared by a joint committee of the Association of British Chemical

Manufacturers and the British Chemical Plant Manufacturers' Association. The Specification opens with general requirements as to dimensions, enamelling, working pressures, tests, etc., and dimensions are given in tabular form for pans of both shallow and deep type, the capacity of the former ranging from 26 to 100 gallons and of the latter from 10 to 200 galls., the equivalent capacity in litres being also given. Complete key diagrams provided with dimensions are also included. Copies of the specification may be obtained from the British Engineering Standards Association, 28, Victoria Street, London, S.W. 1.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for May* 31)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Brass and copper tubes and sheets	684
Belgium ..	Paint, varnish, enamel	692
British India	Copper wire (tender)..	*
Bulgaria ..	Linseed oil (tender) ..	10754/F.E./C.C./2
,, ..	Lead ingots, sheets and pipes (tender)..	10753/F.E./E.C./2
Canada ..	Litharge	686
,, ..	Steel, copper and brass tubes	688
,, ..	Steel sheets, tinplate ..	689
Denmark ..	Sugar	693
,, ..	Blue vitriol, copperas	694
Egypt ..	Paper (tender) ..	10833/F.E./M.P.
Greece ..	Iron and steel, tinplate, bar tin ..	696
New Zealand	Paper (tender) ..	11404/E.D./M.P.
Rumania ..	Tinplate, galvanised sheets	701
South Africa	Medicinal preparations	690
Spain ..	Paint, tinplate ..	702
Switzerland..	Pig iron, tinplate, steel	706
United States	Steel scrap, pig iron ..	708
,,	Ores, paint, chemicals	709

* Director-General, India Store Department, Branch No. 10, Belvedere Road, London, S.E. 1.

TARIFF CUSTOMS EXCISE

Canada.—Details of the Budget resolution are given in the issue of May 31, together with a list of duties on various goods, including sugar, metals, iron and steel, chemicals, and oils.

Costa Rica.—The list of goods to which no other tax than a wharfage due is applied, now includes pharmaceutical preparations.

France.—The May 31 issue contains information as to the tariff classification of certain goods, among which are included glass, sodium bicarbonate, iron, oil, coal-tar dyes, steel, cadmium, cement, paper, and sulphur.

Germany.—A general export licence has been applied to dyeing materials, mineral oils, soap, cement, artificial silk, leather, rubber, paper, asbestos wares, and electric cables.

Iraq.—Increased import duties are payable on opium, perfumery, artificial silk, and petrol.

South Africa.—It is proposed to reduce the import duty on calf skins and fine leathers. An Act has also been passed prohibiting the sale and manufacture of adulterated leather.

Sweden.—The import duties on iron and steel have been modified.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Reparation Dyes

In reply to various questions, Sir P. Lloyd-Greame said that the Government had taken measures to avoid interruption of delivery of reparation dyes owing to the seizure of dye factories in occupied German territory by the French. A representative of this country visited the factory and the French provided every facility to identify parcels of dyes destined to this country.—(May 29.)

Imports of Dyestuffs

Replying to Mr. Hannon, Sir P. Lloyd-Greame said that imports of coal-tar dyes in 1913 were 18,894·2 tons (£1,892,055), in 1914 10,676·1 t. (£1,291,430), and in 1922 2929·5 t. (£1,326,174). Precise data of the production of coal-tar dyestuffs in the United Kingdom prior to the war were not available, but it was estimated that the output in 1913 did not exceed about 2500 t., largely from imported intermediates, and was valued at less than £200,000. In 1922 the total output, which owing to trade depression was much below capacity, amounted to 9000 t., entirely from home-produced intermediates, and was valued at £3,000,000. These statistics did not include natural indigo or natural dyestuffs.—(May 29.)

World's Output of Cane and Beet Sugar

Sir P. Lloyd-Greame, in answer to Mr. Hannon, said that the world production of cane and beet sugar was as follows :—

	Cane sugar Tons	Beet sugar Tons
1909-1913 (average) ..	9,971,000	8,432,000
1914	11,293,000	8,331,000
1922, latest estimates ..	14,735,000	5,707,000

—(May 29.)

REVIEW

THE CHEMIST'S YEAR BOOK. *Edited by* F. W. ATACK, *M.Sc., D.Sc.*, and L. WHINYATES, *A.M.C.T., A.I.C. Vol. I., pp.* 422; *Vol. II., pp. vii*+684. *Manchester: Sherratt and Hughes*, 1923. *Price* 21*s*.

To review a book so full of minute detail as this is a very difficult task, as only in detail can it be truly criticised, and the space at command does not allow of much detail.

The volumes evidently make two professions: to be a storehouse of numerical data and tables of physical and chemical constants; and to serve as a sort of condensed textbook of analytical chemistry, pure and applied. The first object appeals strongly to the present reviewer. In regard to the second, it seems to him that the parts of the work dealing with the analytical requirements of special industries will be each one superfluous to the specialist in that industry, and likely to be insufficient for those who are only making an acquaintance with it. The continued development of this part of the work, however, seems to indicate that it meets a general want; but the reviewer would like to ask whether the book could not be so arranged that all the mathematical and other tables, and lists of numerical constants and data, should be grouped in one volume, all the analytical work in the other, and the volumes sold separately. The high price of the book is a serious hindrance to one who knows beforehand that half of it, more or less, will be of no use to him. If at the same time additional tables were inserted—specific and latent heats, heat conductivities, thermochemical, electrical and electrochemical data—the usefulness of the book would be further increased.

Accepting the dual object of the book, it is clear that for full usefulness the analytical directions should be full, clear and unambiguous, however concise they may be; and that the tables and data should be accurate, systematic, and in orderly arrangement for quick and easy reference. It is obviously impossible, in any reasonable time, to test the whole book in these respects: all that can be done is to take parts at random and assume that they are typical; and the reviewer has examined parts that happen to be familiar to him.

In the section on Fuel, for example, the directions for sampling coal are altogether insufficient; they could be followed carefully and literally, and yet a sample be obtained not in the least representative of the parcel sampled. If space does not permit of full and detailed directions for such an operation being given, in language which leaves nothing to the imagination of the (as yet) ignorant operator, they should not be given at all. On the same page the statements that coal at 105° C. may increase in weight through absorption of *air*, that to determine ash coal is *carefully heated* in a crucible, and that sulphides are to be oxidised by *a trace* of bromine water: on the next page the use of two differing methods, with differently specified conditions (and different unspecified conditions) for determining the volatile and the non-volatile portions of a coal; and the suggestion on p. 707 that *petroleum ether* could be used to determine the water in a fuel oil: all these are indications of the lack of that precision which is so necessary in such descriptions—a lack which is not made up for by the vague statement that such experiments should be performed "in a standard manner."

In the cement section, the direction, after adding nitric acid to the concentrated filtrate from the lime determination, to *warm gently* to expel ammonium salts, and the omission from the British Standard Specification of the requirements for tensile strength, setting time, and soundness (though those for specific gravity and fineness are given) are similar instances.

Some of the tables exhibit the same features. Looking at the solubilities of gases, for example, in the table of General Properties, we find, in a column headed "Solubility in 100 parts of water at 15° C.":

Ammonia	597 volumes
Chlorine	1:2·6 volumes
Chlorine dioxide ..	20 volumes : 1
Hydrochloric acid ..	82·5/0°C.
Hydrogen	1·93 volumes
Hydrogen sulphide ..	1:3·23 volumes at 15° C.
Sulphur dioxide ..	688

Of all these, the solubility of hydrogen only corresponds with the heading. The ammonia figure is the amount dissolved by 1 volume, not by 100 volumes, of water; the hydrochloric acid figure is given by weight, whilst all the others are by volume; the figures for chlorine, chlorine dioxide, and hydrogen sulphide, do not show whether 1 volume of water dissolves, for instance, 2·6 volumes of chlorine, or 2·6 volumes of water dissolve 1 volume of chlorine; and what the figure for sulphur dioxide means the reviewer has not been able to discover. Could not all these and similar data be put on one basis, or, if treated separately, be so expressed in each case as to be placed beyond ambiguity?

Some of the tables are indeed misleading. On p. 699, for example, "Miscellaneous data concerning fuels," we have coals described as bituminous, anthracite, and *dry*; and the dry coal contains 15 per cent. of oxygen: is this typical of anything? Further, whilst the bituminous coal (presumably typical) contains 4% of ash, the coke below contains 12%. Further still, whilst this coke, with 88% of carbon and 12% of ash, has a calorific value of 8080, the wood charcoal preceding it, containing 5% more carbon and 5% less ash, has a calorific value of only 7500. At the foot of the table we are told that *L* is the "Theoretical quantity of air required in kilos"—for what is not stated, but examination of the figure in the case of coke shows that it is for the complete combustion of

1 kilo. We also learn that G is the "Weight of the products of combustion in kilos"; but how 1 kilo of coke and 10·6 kilos of air manage to form 22 kilos of "Products of combustion" is not easy to see. It is further mystifying that whilst i is said to be the "Coefficient of radiation," there is no i to be found in the table; and the significance of V, the "Increase in volume in c.c.s" is, from the reviewer at least, entirely hidden.

The mischief of this kind of thing is that it destroys confidence in the other parts of the book; and the reviewer earnestly hopes that in future issues there may be careful revision in this respect, and also in respect of arrangement, both in individual tables (see p. 695, where peat and peat derivatives are scattered over the table in three different places, and sawdust briquettes are separated from woods by the whole range of coals, cokes, lignites and peat) and in series of tables, as on p. 716, where a table dealing with liquid fuels is separated from what should be its neighbours, and intercalated between two tables dealing with gases, or as in the early part of the second volume, where "Cryoscopic constants" and "Ebullioscopic constants" are separated from latent heats, and inserted, along with refractive indices, between viscosity and specific gravity.

The reviewer bears willing testimony to the patient labour that has gone to the collection and compilation of such a mass of detail; and in calling attention to what seem to him shortcomings or weaknesses rather than pointing out the excellences of the book, does so in no spirit of fault finding, but with a sincere desire to see the book improved. It challenges comparison, of course, with the "Chemiker Kalender." That is obtainable for 7s. 6d., against the 21s. charged for this. It surpasses this in clearness of type and opacity of paper; and unless the English book can surpass the German one in the accuracy and arrangement of its contents, so as to prove itself superior in ease and convenience of actual use, the patriotism of would-be users will be hard put to it to bear the strain.

J. T. Dunn

NIGERIAN OUTPUT OF TIN

The Mines Department of Nigeria reports that in 1921, 7225 tons of tin ore was won (158 t. less than in 1920), and 7181 t. of tin ore valued at £914,789 was exported. The low price of tin depressed the industry during the year, but total costs have been reduced from £150 to £116 per ton, and some of the companies have amalgamated to reduce overhead charges. The mining industry has been assisted by the grant of special concessions such as a new scale of royalties, reduction of rates, etc., and these have undoubtedly saved many companies from going into liquidation.—(*Ch. Comm. J.*, *May* 4, 1923.)

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The chemical market shows little signs of improvement. The last few weeks have been clouded over by distinct depression in most directions, and as proof of the abnormal conditions of trading may be taken the fact that prices as a consequence of the depression have in very few cases indeed shown any tendency to become easier. Chemicals are evidently being sold at reasonable prices comparable with costs; production or powers of production are sufficient to meet demand, and prices of home-made compounds do not depend as yet on the control of market speculation. Very little forward buying is taking place and as a consequence business is of a hand-to-mouth nature and small in volume.

Acetic Acid, 40% tech...	£24 per ton. Still firm, but rather less inquiry.
Acid Hydrochloric ..	3s. 9d.-5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw. ..	£24 10s. per ton. Quiet.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d.-£8 per ton.
Arsenic (White) ..	£70-£72 per ton. Not much business passing.
Bleaching Powder ..	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Keen competition for orders, especially export.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d. Very quiet.
Copper Sulphate ..	£27 per ton.
Potash Caustic	£32-£34 per ton. Slightly easier, but stocks still light.
Potass. Bichromate ..	5$\frac{3}{4}$d.-6d. per lb. d/d.
Potass. Chlorate ..	3d. per lb. Somewhat firmer but very quiet.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76% ..	£20-£21 per ton. Quieter.
Soda Crystals	£5 10s. per ton carr. paid stations; £5 5s. at certain ports—Home trade.
Sod. Acetate 97/98% ..	£26 per ton.
Sod. Bicarbonate ..	£10 10s. per ton.

Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	2⅞d.-3d. per lb. Small demand.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, conc.	£16 per ton carr. paid. Little doing. Keen competition for export orders.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£26-£28 per ton according to quantity.
Carbon Black	1s. 5½d. per lb. ex wharf. Still very scarce.
Chromium Oxide	1s. 5d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb. Firmer on advance in price of Rape Seed Oil.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood-distillation products.

Acetate of Lime—	
Brown	£10 15s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 10s. per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 9d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£6 per ton d/d.
Brown Sugar of Lead	£45 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 5d. per lb. Little movement in the market.
Crude 60's	3s. 4d.-3s. 6d. per gall. Not much business.
Acid Cresylic—97/99	2s. 1d.-2s. 5d. per gall. Demand fairly good.
Pale 95%	1s. 10d.-2s. 4d. per gall.
Dark	1s. 10d.-2s. 1d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	9d.-9½d. per gall. Not much demand.
Unstrained	8¾d.-9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8½d. per gall. Business slack, abundant supplies.
Pure	2s.-2s. 2d. per gall.
Toluole—90%	1s. 9d.-2s. per gall. Quiet.
Pure	2s.-2s. 6d. per gall. Not much inquiry.
Xylol	3s.-4s. per gall. according to quality. Good demand.
Creosote—	
Cresylic 20/24%	11¼d.-1s. per gall. Not much business.
Middle Oil	8d.-9½d. per gall. Market steady. Fair demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d. per gall.
Solvent 90/160	1s. 7d.-1s. 9d. per gall. Fewer inquiries.
Solvent 90/190	1s. 5d.-1s. 8d. per gall. Market more active.
Naphthalene Crude—	
Drained Creosote Salts	£7-£10 per ton.
Whizzed or hot pressed	£11 10s.-£14 per ton. Plenty of inquiries.
Naphthalene—	
Crystals	£18 per ton.
Flaked	£16 10s. per ton.
Pitch, medium soft	No business for this season. Prices for Autumn delivery 120s.-135s. per ton.
Pyridine—90/140	12s. 6d.-13s. 6d. per gall. Dearer. More inquiry.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Since the beginning of June there has been a decided improvement in business in aniline dyestuffs. There is considerably more inquiry about and orders have improved both in number and weight. There is every likelihood of still further improvement in the near future.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.

Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 9d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works. Good demand.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market has been quiet, and prices weaker in consequence of lack of business.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. 3d.-3s. 4d. per lb. Steady demand. Price well maintained.
Acid, Benzoic	2s.-2s. 9d. per lb. Still very scarce.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8¾d. per lb., less 5%. Less demand owing to cold weather.
Acid, Gallic	3s. per lb. Steady demand.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb.
Acid, Salicylic	2s. 3d. per lb., but 2s. 1d. lb. would buy large quantities.
Acid, Tannic	3s. 3d. per lb. Slightly cheaper.
Acid, Tartaric	1s. 3¾d.-1s. 4d. Demand poor owing to cold weather
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d. per lb. Slow of sale.
Amidopyrin	14s. per lb. Firm.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quality.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. per oz. No inquiry.
Barbitone	20s. per lb. Certain holders are willing to sell at slightly lower figures.
Benzonaphthol	4s. 6d. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Better inquiry. Prices steady. Potass. 8d., Sod. 9d., Ammon. 10d. per lb.
Calcium Lactate	2s. 9d. per lb. for best makes.
Chloral Hydrate	4s. 3d. per lb. Some holders would accept 4s. to clear stocks.
Chloroform	2s. 2d. per lb. for cwt. lots. Slightly weaker.
Creosote Carbonate	10s. per lb.
Formaldehyde 40%	£90-£92 per ton. Very firm.
Guiacol Carbonate	8s. 6d. per lb.
Hexamine	4s. per lb. would now be accepted by most holders.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Market good with considerable inquiry.
Magnesium Carbonate—	
Light Commercial	£37-£38 per ton net, according to quantity.
Magnesium Oxide—	
Light Commercial	£85 per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	1s. 9d.-2s. per lb. Good demand.
Menthol	35s. per lb. spot.
Methyl Salicylate	2s. 6d. per lb. for carboys. No considerable demand.
Methyl Sulphonal	15s. per lb. Still neglected.
Mercurials	Unchanged. Market rather firmer.
Paraformaldehyde	3s. 6d. per lb. Weak.
Paraldehyde	1s. 7d. per lb. A lower rate wanted for forward delivery.
Phenacetin	6s. 6d. per lb. spot value. Very steady.
Phenazone	7s. 6d. per lb. Very firm.
Phenolphthalein	6s. per lb. now wanted by most holders.
Potass. Bitartrate—99/100% (Cream of Tartar)	96s.-98s. per cwt., less 2½%.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. Demand still continues good.
Potass. Permanganate	10d. per lb. for large quantities. Forward market very much firmer.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	6s. per lb. still quoted on a weak market.
Salol	2s. 9d. per lb. Not quite so firm.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 9d. per lb. now wanted by holders. Still in short supply, fresh stocks being quickly absorbed.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality.
Sod. Hyposulphite—Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	80s.-82s. per cwt. net.
Sod. Salicylate	Demand not so good. Powder is slightly weaker at 2s. 8d. per lb., with crystal at 2s. 10d. per lb.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. per ton, according to quantity for home trade, 1-cwt. packages included.

Sulphonal	15s. per lb.	
Tartar Emetic	1s. 2d.-1s. 4d. per lb.	
Thymol	17s. per lb.	for genuine white.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.	
Aubepine	14s. ,, ,,	
Amyl Acetate	3s. ,, ,,	
Amyl Butyrate	7s. ,, ,,	
Amyl Salicylate	3s. 6d. ,, ,,	
Anethol (M.P. 21/22° C.)	4s. 3d. ,, ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,	
Benzyl Alcohol free from Chlorine	3s. ,, ,,	
Benzaldehyde free from Chlorine	2s. 9d. ,, ,,	
Benzyl Benzoate	3s. 3d. ,, ,,	
Cinnamic Aldehyde	14s. 9d. ,, ,,	
Coumarin	18s. 6d. ,, ,,	Considerably dearer.
Citronellol	19s. 6d. ,, ,,	
Citral	9s. 6d. ,, ,,	
Ethyl Cinnamate	15s. ,, ,,	
Ethyl Phthalate	4s. 3d. ,, ,,	
Eugenol	11s. 6d. ,, ,,	
Geraniol (Palmarosa)	30s. ,, ,,	
Geraniol	5s. 6d.-12s. 6d. per lb.	
Heliotropine	8s. per lb.	
Iso Eugenol	16s. 6d. per lb.	
Linalol ex Bois de Rose	21s. ,, ,,	
Linalyl Acetate	25s. 6d. ,, ,,	
Methyl Anthranilate	6s. ,, ,,	
Methyl Benzoate	8s. 6d. ,, ,,	
Musk Xylol	9s. 6d. ,, ,,	
Phenyl Ethyl Acetate	10s. ,, ,,	
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,	
Rhodinol	45s. ,, ,,	
Safrol	2s. 3d. ,, ,,	
Terpineol	3s. 1d. ,, ,,	
Vanillin	23s.-24s. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.	
Anise Oil	2s. ,, ,,	
Bergamot Oil	12s. 6d. ,, ,,	spot.
Bourbon Geranium Oil	31s. 6d. ,, ,,	
Cananga Oil, Java	9s. ,, ,,	
Cinnamon Oil, Leaf	4½d. per oz.	
Cassia Oil 80/85%	8s. 6d. per lb.	
Citronella Oil—		
Java 85/90%	4s. 2d. ,, ,,	
Ceylon	3s. 4d. ,, ,,	
Clove Oil	8s.-8s. 6d. per lb.	
Eucalyptus Oil 70/75%	1s. 9d. per lb.	
Lavender Oil, Mont Blanc 38/40%	13s. ,, ,,	
Lemon Oil	3s. 1d. ,, ,,	
Lemongrass Oil	2¾d. per oz.	
Orange Oil, Sweet	12s. 6d. per lb.	Advanced.
Otto of Rose Oil—		
Anatolian	24s. per oz.	
Bulgarian	30s. per oz.	
Palma Rosa Oil	17s. 6d. per lb.	
Peppermint Oil—		
English	80s. ,, ,,	
Wayne County	13s. ,, ,,	
Japanese	6s. 4½d. ,, ,,	
Petitgrain Oil	7s. 9d. ,, ,,	Lower.

TRADE NOTE

Imports of Chemicals into the United States

The statistics of the imports of chemicals in 1922 show that $63,126,200 of duty free, and $37,477,500 of dutiable chemicals were imported, the aggregate gain being 24 per cent., whereas the export trade increased only by 1·4 per cent. Amongst particular groups, imports of explosives increased by 11 per cent., paint, pigments and varnish by 55 per cent., and fertilisers by 47 per cent. An increase of 28 per cent. was shown by perfumery, etc. and of 23 per cent. by medicinal and pharmaceutical preparations. Imports of coal-tar products were valued at $11,012,800, a decline of 3 per cent., decreases occurring particularly in naphthalene, creosote oil and benzene. Imports of coal-tar intermediates, however, increased from 867,300 lb. in 1921 to 2,136,670 lb. in 1922; the smaller imports of indigo and coal-tar medicinal chemicals were compensated for by increases in the alizarin and coal-tar dyes imported. Amongst general heavy chemicals, imports of the following showed gains as compared with the previous year: oxalic acid (3 per cent.), arsenic compounds, glycerin (30 per cent.), citrate of lime (1000 per cent.), sodium compounds (90 per cent.), varnish (55 per cent.).—(*U.S. Com. Rep., Apr.* 23, 1923.)

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JUNE 15, 1923 No. 24

EDITORIAL

THE perusal of certain remarks, which appear in another part of this number, on electric accumulators and a faint recollection of some recent articles on co-ordination, tautomerism and kindred topics suggested that the modern ideas as to chemical combination might be suitable for editorial comment. An article is sometimes instructive to the reader, but unless the writer is well acquainted with the subject he gets far more instruction than do the readers. It always affords us amusement in our editorial sanctum to find—by writing—how little of exact and elementary knowledge on most subjects is readily accessible in the text-books at hand. Rough approximations suffice for a while in science, but as knowledge becomes more precise these become inadequate and the complex idea takes its place, yielding in due course to a further scheme of a further order of complexity. The simple action of sulphuric acid on a mass of lead oxide seems to involve a whole set of mutually interacting forces as complicated as the various forces which keep the solar system smooth and comfortable. Formerly the good old rule, the simple plan, sufficed, that hydrogen, carbon and nitrogen combined to make prussic acid, one atom of each element being required. Then some dissatisfied chemist, some Paul Pry, hoping he or she does not intrude, wants to know how the three atoms fit into each other. Is the hydrogen atom attached to the carbon or the nitrogen or both ? Or does it like Captain Macheath, sip each flower and change every hour ? We gather that Miss Usherwood is of opinion that it does. In what we used to call prussic acid the hydrogen is sometimes attached —not very firmly—to the carbon, in which case the real name of the compound is formonitrile; sometimes the hydrogen has a liaison with the nitrogen and in this case the compound is carbylamine. But one of these substances readily changes into the other and while you are measuring some specific property which enables you to identify the exact position of the little wanderer it has changed its quarters and incidentally the chemical properties of the substance. *Dum loquimur fugerit invida.*

* * *

It seems that most of the discussions at Cambridge next week will involve a consideration of those minute particles and minute forces which build up atoms or molecules. The study of soap solutions involves knowledge of colloids, a study of infinitesimals ; the discussion on catalysis requires a phraseology founded on the theory that a surface of some metal may collect and incorporate in it some few molecules or atoms of another substance. We need not be surprised that modern pure chemistry is mainly concerned with particles, which lie on the very border line of visibility, ponderability and credibility. We have outlived the period when a successful chemical experiment was recognised by a flash, a bang, a stink. We gather from Mr. Holmyard's article that the chemist in olden days was not merely organic, but sometimes even aromatic. This is really off the main line of the argument. We began with prussic acid, a compound known to every novelist and to some poets. She drank prussic acid without any water and died like a Duke or a Duchess's daughter, so we were told in our youth. But what we have not yet been told is whether prussic acid without any water is an active compound, even is it an acid and is it the formo-nitrile or the carbylamine which has acidic properties ? We fancy while the full dress discussions are taking place some of us may argue in a timid and private manner some of these simpler topics, but if Calorifer and Lucifer are to have a bout there may be some pretty sword play and we will come and watch. Lucifer—we mean the first bearer of the name—was the morning star ; by what species of degradation did the name become attached to the prince of darkness ? Perhaps some reader can give us this little history of a change of meaning. Has the photographer who has not yet taken Holy Orders reached this stage in his study of divinity? We hesitate to appeal to our clerical contributor himself, as he complains of advancing years and even this slight trouble, this grasshopper, may become a a burden to him.

* * *

The Anglo-Batavian Society entertained Prof. H. A. Lorentz, F.R.S., to dinner at the Langham Hotel, London, on Wednesday, June 6, as a mark of the distinguished services which he has rendered to science. The chair was taken by Sir Walter Townley, who a few years ago was the British Ambassador at the Hague. Among those present were Lord Haldane, Prof. Donnan, Sir Frank Dyson and Lady Dyson, Sir Richard Glazebrook and Lady Glazebrook, Profs. Forsyth and Whitehead, Sir W. Napier Shaw and Lady Shaw, and several others well-known in the world of physics or as being interested in the promotion of cordial relations between the English and Dutch. Speeches were made by Sir Walter Townley, Prof. Lorentz, Lord Haldane, Sir Frederick Mott, Prof. G. N. Lewis, of California, and Sir William Bragg, and it was evident that those present were delighted to meet Prof. and Mrs. Lorentz and renew old friendships.

Some species of exchange of ideas between England and Holland, so far as science is concerned has been organised, and Prof. Lorentz has been in England now for some little time, and has delivered a series of lectures, and lectures by British physicists are taking place in Holland. It is very important that this sort of exchange of views should take place. In Chemistry, Monsieur Kestner a few years ago came over here to lecture before the Society of Chemical Industry. How important and valuable his visit has been! The following year Prof. Louis and Sir William Pope delivered addresses in Paris, and now the chemists from over a score of countries are meeting in friendly conclave at Cambridge. Some sciences are particularly suitable for such international co-operation, and, as Lord Haldane said, science has no frontiers and knows nothing of provincialism. There are some difficulties in cordial gatherings of chemists from all countries which do not, fortunately, exist in physics and mathematics, and the Anglo-Batavian Society has been singularly fortunate in choosing so genial and accomplished a man as Prof. Lorentz to assist in these sciences. In both these he is distinguished, in mathematics he is in the front rank, and in physics he suggested a formula for the refraction of light which has been supported by a good deal of experimental evidence. As professor of physics at Leyden he has not only worked himself, but also trained up others to work at the alteration of lines in spectra when placed in a magnetic field, at long-wave radiation from hot bodies, on the Michelson-Morley experiment and its relation to the hypothesis of Einstein.

THOMAS NORTON, AN ALCHEMIST OF BRISTOL

By E. J. HOLMYARD

Head of the Science Department, Clifton College

We have been told that "*la chimie est une science française*," but we may take comfort in the thought that the honour of having introduced chemistry to Christian Europe must be given to England. On February 11, in the year 1182 of the Spanish era, that is 1144 A.D., the Englishman, Robert of Chester, finished the first translation from the Arabic of a book on chemistry, the *Book of the Composition of Alchemy*, ascribed to the Monk Morienus, teacher of Khālid ibn Yazīd. In the preface to his translation Robert says: "*quoniam quid sit Alchymia, et quae sit sua compositio, nondum vestra cognovit latinitas, in praesenti sermone elucidabo.*" This interesting passage enables us to fix the origin of European chemistry and also indicates that the word *alchemy* was used not merely, and perhaps not mainly as the name of a science, but also as the name of a *substance*, to wit the philosopher's stone.

The seed thus sown by Robert of Chester fell upon fertile ground and quickly germinated. In the next century there lived Roger Bacon, who, if he did not (as some assert) invent gunpowder, was at least the first to mention it and to describe its preparation, and who seems to have had a better conception of scientific method than any other man prior to his great namesake of the seventeenth century. The widespread interest in alchemy in England in the next hundred years, is witnessed by Chaucer's *Tale of the Chanon's Yeoman*, which shows that the art had obtained so great a hold upon the country that it could be made the subject of a popular poem. The unfortunate yeoman describes his woes as laboratory assistant to the "chanon" with a taste for research and admits that his intelligence is not sufficient to cope with the technical language:—

> "There is alsoe full many another thing
> That is to our Craft apertayning:
> Though I by ordre hem ne reherce can,
> Bycause that I am a leud man.
> Yet wol I tellen hem as they come to mynde,
> Though I ne can sette hem in her kynde,
> As bole Armonyake, Verdegreece, Boras."

As for alchemists the yeoman says that:—

> ". . . . evermore where that ever they gone
> Men may hem ken by smell of Brimstone:
> For al the world they stynken as a Gote."

Some fifteen years after Chaucer's death, was born George Ripley [1415(?)-1490], who belonged to the Abbey of St. Augustine in Bridlington, and there pursued the study of chemistry with such ardour that at last the abbot and other monks grew weary of him, upon which he joined the Carmelite fraternity at Boston. He was a remarkable man in many ways, not the least being that, according to the *Biographie Médicale*, (Paris, 1820-25), he was the uncle of Roger Bacon, who predeceased him by two hundred years!

Among Ripley's disciples in the "Divine Science" was Thomas Norton. The Nortons were one of the chief families at Bristol, and lived in a large house on the site now occupied by St. Peter's Hospital. Thomas Norton's father, or at least the Norton who was probably his father, was sheriff of Bristol in 1401 and mayor in 1413; he was also M.P. for Bristol for many years. Thomas Norton himself was a privy councillor and seems to have been a man of substance, deriving his wealth from commercial undertakings the exact nature of which is not stated. He began to study chemistry at an early age, and, according to his own account, arrived at a knowledge of the method of preparing the Elixir of Gold at the age of 28. He acquired a great reputation, and, according to Ashmole (quoting from earlier writers), he was "*Alchymista suo tempore peritissimus*, and much more curious in the studies of *Philosophy* than others, yet they passe some undecent and abusive *Censures* upon him, with reference to this *vaine and frivolous Science*, as they are pleased to tearme it. . . . Indeed, every one that is educated a *Scholler*, is not borne to affect or be happy in every *Art*, some love one, some another, but few *All*. . . . Commonly, what either a man does not *affect*, or *know*, he *despises* or *condemnes*, yet seldome with any shew of *Reason*. But it is no good *Conclusion* for *Blinde men* to affirme the *Sun* has no *light*, because they were never so happy as to see it."—(*Theat. Chem. Brit.*, pp. 437, 438.)

Norton's chemical knowledge he exposed in three works, the *Ordinall of Alkimy*, the *De transmutatione Metallorum* and the *De Lapide Philosophico*. Of these, the only one that has been published is the first, which is included in Ashmole's *Theatrum Chemicum Britannicum*, (1652), and, in Latin, in Maier's *Tripus Aureus* (1618), and Manget's *Bibliotheca Chemica Curiosa* (1702). Ashmole transcribed his versions he tells us, from a very fine manuscript. "In the search I have made after authentique manuscripts to compleate this worke, a private Gentleman lent me a very fair one of Norton's *Ordinall*, which I have chiefly followed; yet not omitting to compare it with fourteen other copies. It was written in Velame and in an auntient sett Hand, very exact and exceeding neate, the Figures . . . being also most neatly and exquisitely lym'd, and better work than that which was Henry the Seventh's own Booke, (as I am informed by those that have seene both)."

The authorship of the *Ordinall* is revealed in a curious way. "From the first word of the Proeme," says Ashmole, "and the initiall letters of six following chapters (discovered by *Acromonosyllabiques* and *Sillabique Acrostiques*) we may collect the author's Name and place of Residence: For those letters, (together with the first line of the seventh chapter) speak thus:

Tomais Norton of Briseto,
A parfet Master ye maie him call trowe.

"Such like Fancies were the results of the wisdome and humility of the Auncient Philosophers, who (when they intended not an absolute concealment of Persons, Names, Misteries, etc.), were wont to hide them by *Transpositions*, *Acrostiques*, *Isogrammatiques*, *Symphoniaques*, and the lyke, (which the searching Sons of Arte might possibly unriddle, but) with designe to continue them to others as concealed things."

The poem opens with the "Proheme," in which Norton explains his reason for writing the book, and laments the foolishness of both "clerks and laymen," in attempting to follow the enigmas and dark sayings of his predecessors. Alchemy seems to have been as popular a fashion in the fifteenth century as spiritualism is in the twentieth. Even:—

" . . . common workemen will not be out-laste,
For as well as Lords they love this noble crafte;
As Gouldsmithes whom we shulde lest repreve
For sights in their Craft moveth them to beleeve:
But wonder it is that Wevers deale with such warks,
Free Masons and Tanners with poore Parish Clerks;
Tailors and Glasiers will not thereof cease,
And eke sely Tinkers will put them in the prease
With greate presumption."

As masters of the Art, Norton mentions "Hermes, Rasis, Geber, Avicen, Merlin, Hortolan, Democrit, Morien, Bacon and Raimond," but complains that, to use his own delightful expression, "their Cloudy Clauses dulled many men." His advice to the novice is not to trust these men and their books, but to "give Credence to this booke and mee," and "to lerne well this Clause, Nothing is wrought but by his proper Cause." He also solemnly warns his readers (doubtless with tongue in cheek) never to slide into falsehood, "but stedfastly your minde must be set Fals Colloured Metall never to counterfett." He modestly describes his *Ordinall* as "a Boke of incomparable price, whose trewth shall never be defiled," and, having given a summary of the contents of the seven following chapters, closes his "Proheme" with a prayer to the Almighty.

In the first chapter Norton sets out to explain what manner of people may hope to acquire a knowledge of the secrets of alchemy, and why this science is called blessed and holy. With a naïve belief in the ancient accounts of transmutation he mingles some shrewd observations which, if it were our custom to hang texts in our laboratories, might still have a salutary effect so used:—

"Blessed is he that maketh due proofe."

"With due proofe and with discreet assaye,
Wise men may learne new things every day."

Those who do not make due proofe:—

" . . . lewdly believe every Conclusion,
Be it never so false an elusion:
If it in boke written they may finde,
Thei weene it trewe, thei be so lewde of minde."

Chapter II deals with the "nice Joyes of alchemy, with the great paine" as well. It contains some autobiographical information, from which we gather that Norton rode over a hundred miles to meet his master, and stayed with him forty days, in which time he learned all the secrets of alchemy. Having returned to Bristol, he put his newly-acquired knowledge to the test of experience and succeeded in preparing the great Elixir of Gold, only to have it stolen from him by a dishonest servant. He was so discouraged by this reverse of fortune, that he would have "noe more of Alkimy," but turned his attention to the Elixir of Life. Here again, he was unlucky, for after he had made it, it was stolen from him by a merchant's wife, who is generally said, on inadequate grounds, to have been the wife of William Canynges. Canynges rebuilt the church of St. Mary Redcliffe in Bristol, and had a master-mason whose name was Norton, but there is, as far as I am aware, no evidence that the mason was also the alchemist.

Norton's third misfortune was the theft of his *Quintessens* :—

"Which sinfull people tooke me fro,
To my greate paine and much more woe."

Whether Thomas Norton was a conscious impostor or not is hard to decide, but it seems likely that he was. His tales of his adventures with the elixirs are rather more than suspicious, and, in spite of his repeated promises to speak "in homely wise," it is quite impossible to make anything out of his tenebrous instructions. The *Ordinall* furnishes us with additional evidence of the parlous state of chemistry between the days of Roger Bacon and Paracelsus. In spite of the fact that the mineral acids had become known to the Western world about the year 1300 A.D., and chemists were, therefore, provided with the essential factors for incalculable progress, astonishingly little advance was made. In chemical theory it is not far from the truth to say there was no advance whatever. It is difficult to discover the reason for this stagnation. Probably the theory of transmutation had become an obsession and had stifled the growth of new ideas; at the same time it must have been partially discredited by intellectual men aware of the ever-recurrent failures of attempts at transmutation, and the time was not yet ripe for another generalisation of sufficient stimulus. The comatose state of chemistry at the end of the fifteenth century is shown by the ease with which Paracelsus made it the handmaid of medicine, and the utter lack of realisation that it was an independent science.

Norton's poem enables us to obtain a conspectus of chemistry as it was just before the birth of Iatrochemistry, and its sprightly style makes it easy to read; but as a serious contribution to the science it is negligible. Underneath Norton's chemical theory is the inevitable substratum of Aristotelianism. He says :—

". . . . of Alkimy the trew foundation,
Is in Composition by wise graduation
Of Heate and Cold, of Moist and of Drye,
Knowing other Qualities ingendered thereby;
As hard and soft, heavy and light,
Rough and smoothe, by ponders right,
With Number and Measure wisely sought."

The influence of the stars he admitted, and the whole system of thought is confused, illogical and puerile. Yet there are redeeming features. Norton insists upon the necessity of employing all the senses, as well as the intelligence, in the study of alchemy. Smell, for example, is not to be despised, for it may reveal facts otherwise imperceptible. And this because odours have definite causes—causes which appear humorous to us, but which Norton describes with the utmost gravity :—

"The cause of Odours to know if you delight,
Foure things thereto be requisite.
First that suttill matter be Obedient
To the working of Heate, for to present
By a fume the liknes of the same thing,
From whome that fume had his beginninge.

* * * *

Heat maketh Odours, Cold shrinketh, by reason
Dunghills in Summer stink more than in Winter
season.
Pleasant Odours ingendered be shall
Of cleane and Pure substance and fumigale,
As it appeareth in Amber, Narde, and Mirrhe,
Good for a Woman, such things pleaseth her."

The various kinds of smells arise from the action of great or lesser heat upon more or less pure material :—

"But of Pure substance with a Meane heate,
Be temperate Odours, as in the Violet;
Of a meane heate with substance impure,
Is Odours misliking, as Aloes and Sulphure:
But when Naturall heate beginneth to spill,
Then thereof ariseth heavie smell.

* * * *

Stinch is a Vapour, a resolved fumositie
Of things which of Evil Complexions be."

Taste, again, is a useful servant, but substances must be tested with caution, especially the Elixirs. For :—

"A lewde Mañ late that served this Arte,
Tasted of our *White Stone* a parte,
Trusting thereby to find releefe,
Of all sickness and of all greefe,
Whereby the Wretch was sodenly,
Smitt with a strong Paralisie;
Whom my *Master* with great Engine,
Cured with *Bezoars* of the Mine."

Moreover :—

". . . Manie things be of good Smell,
Which to Tast be found full ill:
For they maie be abhominable sower,
Over-sharpe, too bitter, or of great horrour."

Norton goes to some length in describing the apparatus necessary for the operations of alchemy. Each process has its own instruments without which it may be impossible to bring it to a successful completion. Thus :—

". . . workes of Division and Seperation
Have small Vessells for their Operation;
But Vessells broade for Humectation,
And some deale broad for Circulation;
But longe Vessells for Precipitation.

* * * *

Of Vessells, some be made of Leade,
And some of Clay both quick and deade ;
Dead clay is called such a thinge,
As hath suffered greate roastinge ;
Such medled in powder with good raw Claye,
Will Fier abide and not goe away."

The furnaces too, must be carefully made, and different forms of them are required for different operations. Norton tells us that he himself had invented several new varieties :—

" In this Boke portraied finde ye shall.
One Furnace by me is found of newe . . .
Threescore degrees divers ye maie gett,
For threescore warkes, and everie-ech of divers Heate,
Within that Furnace, to serve your desire,
And all this served with one little Fier,
Which of a Foote square onlie shalbe,
Yet everie-ech of the threescore as greate space as he."

The sixth chapter ends with a warning against geomancy, negromancy, and, within limits, astrology : " Trust not in Geomantie, that superstitous Arte ; " " Trust not, ne love not Negromancy."

The final chapter deals with the regimen of fire, which Norton declares to be of the utmost importance. Indeed, he who knows this matter strongly is to be considered a perfect master of the Art. As the ancients said, *Totum consistit in ignis regimine*, a solitary rule, through the neglect of which :—

". . . manie of *Gebar's Cookes*
Deceived were though thei be wise in Bookes."

With this discussion the book ends. What are we to think of fifteenth century chemistry if such a farrago of nonsense is typical ? In the first place it seems clear that as an intellectual science, chemistry in those days was practically non-existent. Europe had not properly appreciated her great legacy from Islam, and the philosophy of chemistry had withered. But through the dark years the life of the science had been preserved in the technical traditions in the secrets of the craftsmen, which could not fail to become more numerous and more extensive as generation succeeded generation. It is here that we must look for the real progress of chemistry in mediæval Europe. With the invention and spread of printing, and with the new mental activity of the Renaissance, conditions changed. After a century of assimilation and re-assimilation of ancient learning, a more vigorous spirit was born, and the mass of facts accumulated during preceding centuries was quickened to vigorous life.

It is, indeed, a sorry picture which Norton's *Ordinall* presents to us. When we think of the state of the natural sciences in Islam in the seventh to the twelfth centuries, we cannot fail to be depressed by the retrograde movement which occurred in Europe afterwards. Charles the Hammer's defeat of the Arabs at Tours was a defeat also for Science ; a defeat from which she did not completely recover for some six hundred years.

Nevertheless, the *Ordinall* has its amusing side, and we may with good will accede to its author's parting request :—

" All that hath pleasure in this Boke to reade,
Pray for my Soule, and for all both quick and deade."

FREE SULPHUR IN MOTOR FUELS

By E. C. CRAVEN, M.Inst.Pet.Tech., F.C.S.

The corrosion of copper, and to a very much smaller extent its alloys, by hydrocarbon spirits, is well known to tar and petroleum distillers. Most motorists also have at some time been troubled by the blackening and scaling of copper gauzes, tubing or the like.

This effect has been traced to the presence of sulphur in a free state, which occurs to a greater or less extent in all the motor spirits now on the market. Hitherto there have been qualitative methods only for the determination of this free sulphur. Usually a vessel or strip of copper is exposed to the action of the spirit under certain conditions of heating and time of contact. The amount of blackening due to copper sulphide formation gives an idea of the amount of free sulphur present in the spirit.

Some recent work[*] carried out in the laboratory of Dr. W. R. Ormandy has led to a simple quantitative method for determining the amount of free sulphur in motor fuels. A measured volume of the fuel is shaken with mercury until the whole of the sulphur is converted into mercury sulphide. This is filtered off on a wet asbestos plug, oxidised to mercuric sulphate, and the sulphur determined by barium chloride in the usual manner.

The results of the application of this method to spirits on the market have shown that amounts of free sulphur up to 6 mg. per 100 c.c. are common in petrol. Samples of benzol of English manufacture compare very favourably with imported samples. Alcohol fuels are practically free from sulphur.

The method has been compared against a copper strip test, in which a strip of electrolytic copper foil is present in the distilling flask during the carrying out of complete Engler distillation. The amounts of sulphur corresponding to the appearance of the copper strip at the finish of distillation are as follows :—

Appearance, etc., of copper strip	Free sulphur mg. per 100 c.c.
Peacock or brown tints	Up to 0·5
Black but no scaling	Up to 1·0
Black, scaling on bending	Up to 1·5
Scaling before end of distillation ..	Above 1·5

The fact that a qualitative method now exists for the determination of that sulphur which is so deleterious to copper may result in greater attention being paid to the presence of this particular impurity by producers and refiners.

THE ALKALINITY OF AMMONIA

By A. E. CLARENCE SMITH

Professor Caven (*Chem. & Ind.*, p. 449) quotes with entire agreement an argument by Holleman to the effect that ammonium hydroxide must be a strong base since ammonium chloride is inappreciably hydrolysed in solution; the feeble basicity of ammonia solutions thus being really due to the great tendency of ammonium hydroxide to split up into ammonia and water.

But surely a little consideration will serve to show that Holleman's argument is in fact misconceived: ammonium hydroxide may possibly be a strong base, but this cannot be established by considering the p_H of ammonium chloride solutions. On either view we have the successive equilibria:—

$$NH_3 + H_2O \rightleftarrows NH_4OH \rightleftarrows NH_4^+ + OH^-.$$

If we assume the concentration of uncombined ammonia to be negligible, we can easily obtain, from conductivity or otherwise, a dissociation constant for ammonium hydroxide. This has been done by Bredig and others, and it may be taken that its value, K, does not differ very very much from 2×10^{-5}, thus making the base a weak one.

If, on the other hand, the base is to be strong, we must assume the presence of a large quantity of uncombined ammonia, so that K will be merely an "apparent" dissociation constant. In this case we must consider separately the two successive equilibria shown above, assigning to them equilibrium constants k_2 and k_1 respectively. There is no reason why the "true" dissociation constant, k_1, should not be large, provided we make k_2 correspondingly small; but it is clear that there must be a close relation between these two hypothetical numbers and the value of K, which is experimental.

This relation appears at once when the equations of equilibrium are written out, and, as was first remarked by Kauffman in 1904, has the form:—

$$K = \frac{k_1 k_2}{1 + k_2}.$$

Given k_1 and k_2, we can of course calculate the hydrogen-ion concentration in any ammonium chloride solution in the usual way; and we find that k_1 and k_2 can, by means of the above equation, be eliminated from the resulting expression, K appearing instead. It follows, therefore, that the degree of acidity is determinable with reference to K alone, and will be just as great with the double equilibrium and large value for k_1 assumed by Holleman, as with the simpler state of affairs assumed in Bredig's value for K.

A verbal semi-quantitative elucidation may be given as follows:—When ammonium chloride is dissolved in water and ionised, combination will begin between its cations and the hydroxyl ions of the water. On the view that ammonium hydroxide is a weak base, this combination, and the consequent upsetting of the dissociation equilibrium of the water, will proceed to some length, causing at equilibrium an excess hydrion concentration, the magnitude of which will depend on the relation between the dissociation constants of water and ammonium hydroxide.

On Holleman's view that the base is a strong one, there will be very much less *tendency* for the ammonium and hydroxyl ions to combine; but since the ammonium hydroxide thus produced is now assumed to be almost entirely removed as ammonia and water, the combination will proceed as far as on the other view.

Why, then, is ammonium chloride solution practically neutral, as remarked by Holleman? The answer is that Holleman's apparent expectation of the degree of hydrolysis is an exaggerated one. In a chloride where the base has a dissociation constant of 2×10^{-5}, the "fraction hydrolysed," to use the customary but very objectionable term, will, in normal solution, be only about 3 parts in 100,000, producing an almost negligible degree of acidity.

It may be pointed out that Bredig's value for the dissociation constant of ammonium hydroxide is almost exactly the same as that of acetic acid, so that ammonium chloride solutions would be expected to be only as acid as sodium acetate ones are alkaline.

Furthermore, the acidity of ammonium chloride solutions, small though it is, has been measured by Denham (*Trans. Chem. Soc.*, 1908), by means of the hydrogen electrode. By this method he found the hydrolytic constant to be about 3×10^{-10}, whereas that deducible from Bredig's dissociation constant of ammonium hydroxide is about 5×10^{-10}. These figures are in quite sufficiently close agreement, especially as Denham considered that his values for this substance were not very accurate.

Denham also found, as one would expect, that the passage of plain hydrogen through the electrode continually carried off ammonia produced by the hydrolysis.

Enough has been said to show that, although it is quite possible, by assuming the presence of much uncombined ammonia in ammonia solutions, to formulate a mechanism whereby the true dissociation constant of ammonium hydroxide may be increased from its apparent value of 2×10^{-5} to that of a strong base, yet the observed degree of hydrolysis of ammonium salts does not throw any light on the problem.

A reference is desirable to the intermediate position adopted by Professor Moore (*Chem. & Ind.*, p. 343), who is led by thermodynamical and other considerations to assign to k_2 and k_1 the respective values of 1·15 and $3{\cdot}41 \times 10^{-8}$ These are seen to fulfil the Kauffman relation when it is noted that the second is expressed in c.c. units, and in litre units becomes $3{\cdot}41 \times 10^{-5}$.

REFLECTIONS ON PATENTS*

By HOWARD CHEETHAM

Some year or more ago Prof. F. Soddy remarked that scientific discoverers were not observed to amass great fortunes and rarely founded families, whereas the originators of the industrial application of a discovery frequently did, and from this foundation he proceeded to erect the super-structure that consequently there was no occasion for the scientific worker to fear any adverse results from any social revolution. I do not propose to discuss the conclusion or to examine the arguments leading to it, but simply to take more or less as a fact the initial statement that scientific work is less renumerative than its industrial application. In the nature of things quite apart from legislative action this tends to be so. As soon as a discovery is made known it ceases to belong to the discoverer and becomes as much the property of any one able to appreciate its nature and bearing. The same thing is true precisely of an industrial invention so far as its inherent nature goes; the only natural hindrances to the general dissemination of industrial inventions and their adoption forthwith by everyone interested are the common reluctance to change and that the inventors may conceivably be already in the industry directly concerned and so get a start or for a time preserve some sort of secret.

The Patent law has modified the natural law as regards industrial invention, but has not so far done much towards interfering with natural conditions as they concern scientific discovery.

In this country it seems to me probable that the restriction of patent rights to "the sole working or making of any manner of new manufacture within this realm to the true and first inventor or inventors of such manufactures, which others, at the time of making such Letters Patents and grants shall not use, so as also they be not contrary to the law nor mischievous to the State by raising prices of commodities at home or restraint of trade or generally inconvenient," was due to the intense realisation of the iniquity of the capricious grant of monopolies over articles of ordinary consumption, rather than to deliberate decision that scientific discovery did not merit reward.

Although three hundred years have gone by since the Statute of Monopolies was passed, the merest suggestion that any concern is or may be a monopoly raises righteous indignation and so it is easy to imagine that those just freeing themselves from the shackles of real monopolies, when all patents were looked upon with the gravest suspicion and as grievances, were not in the best circumstances in which to frame a statute intended to promote progress.

It is obvious from the words of the statute that "any manner of new manufacture" within the realm was the thing visualised as important, and it is quite conceivable that closer attention to the question of who were the first inventors of new manufactures might have led the legislators to discover—it could be fairly called discovery—the fact that scientific discovery sooner or later resulted in new manufacture. It is probable that in 1623 the interval between a purely scientific discovery and its industrial application was much longer than it is now, although to take a comparatively recent example the interval between the fundamental discoveries on which all electrical practice and their extensive industrial application essentially rest was not much less than half of last century and so it would hardly be fair to blame our predecessors for being insufficiently impressed by the apparently idle suggestions of supposedly unpractical philosophers. It has also to be recognised that in one way and another by rule of thumb and the skill or observation of untold generations of craftsmen, industrial applications had already made advances which still command our wonder and respect even though their scientific basis had more or less yet to be discovered. It still sometimes happens that the scientific explanation is subsequent to industrial application, the ordinary steam injector being an instance. For those who do not know the story I may make a digression and mention briefly that Giffard was a rather prolific inventor and not always too keen on industrial application. He was working out a steam pump essentially involving a wheel to form the rotor of a turbine to be driven by a steam jet and being revolved to serve as a pump to feed a boiler. One day the experimental apparatus worked better than ever and Giffard found the rotor had been left out. He reported the result that steam drawn from a boiler would force water into it to a French Patent Agent, who said, "You have told us many wonderful things, but this passes belief." Giffard, however, proving his statement well founded, the patent agent paid the expense of sending him over to Messrs. Sharp, Stewart and Co. here, and the industrial application preceded sound statement of the theory.

Even if the framers of the Statute failed to see there was such a thing as discovery or need to encourage it, it may reasonably be allowed that in their circumstances the limits laid down for the grant of patents were fairly wide, if sufficient weight had been given to the full meanings and implications of "new manufacture" and "first inventor or inventors." Unfortunately, however, the hatred of the word monopoly persisting after the Statute, has continually influenced public and judicial opinion and though there has been a gradual widening of the judicial interpretation of patentable matter to include applied principles and new results with an indication that eventually products themselves might be held patentable, it has been dogged continually by atavistic reminiscences and sentiment, based partly on the ancient antipathy to monopoly, which has materially added to the essential difficulties of decision in conflicts between the interests of patentees and those of the public. To cite case after case in support of this view would be possible, but each case having been decided largely on its own merits and, therefore, with complications interfering with classification as indicating tendencies to broaden and to narrow, I prefer to state the view broadly as a matter of observation. The case of Heath *v.* Unwin, mentioned by Dr. Erhardt in his paper of January (*cf. Chem. & Ind.*, p. 314) and the earlier cases of the same name and the slightly later case of Heath *v.* Smith might be cited as a collection of conflicting opinions favourable and unfavourable to inventors or discovers, although judging from the records it might be said the patentee was responsible for some of his own troubles in so far as having said, " I do not claim this or that, but only the use of carburet of manganese in any process for the conversion of iron into steel," he proceeded to say in so many words, " I claim, fourth, the employment of carburet of manganese in preparing an improved cast steel," and then soon after filing his specification proceeded to put on the market a much cheaper substitute in the shape of coal tar and manganese dioxide (read Judge's remarks in Goodeve's Patent Cases, p. 234-238). There is here rather a variety of conflicting opinions ending in the contradictory conclusion that what did not infringe the patent because it was not an equivalent invalidated the patent because it was previously used and would serve as an equivalent. We may suppose Heath had some reason for not patenting the tar and manganese dioxide mixture, possibly the cost, but it would be interesting to know it.

---

* Read at a meeting of the Manchester Section on May 4, 1923.

The ebb and flow in judicial opinion might be expected to result in gradual realisation of the need to reward by remuneration or otherwise those to whom progress is essentially due. With recognition of this fact, and that there was eventual new manufacture, the statutory mechanism would not be difficult to evolve.

One can hardly affirm that public opinion, even when fairly well instructed, has a very wide outlook, the old prejudice against any supposed monopoly being still rampant and combined in some of us with a less worthy motion that anyone seeing an attractive thing has necessarily the right freely to participate in it, for example, unauthorised " listening-in." Other examples of the effect of this are the present statutory escape from damages provided for the supposed ignorant or innocent infringer and the possible result indicated by Dr. Erhardt in the paper mentioned above, that all patents for products and processes are in jeopardy, which is, perhaps, one way of removing Prof. Soddy's grievance, by restoring industrial inventors to the unrewarded state of scientific discoverers. In my view the desirable end is the greatest possible reward to every one to whom progress is due and concurrently the greatest possible dissemination of the advantages to the community. This principle is clearly indicated in the provisions regarding licences of right in the present Patents Act and the gist of my contention is " let us go further in that direction."

In England the ruling out of pure scientific work from protection by patents has been by judicial interpretation of the statute. In France the reverse was the case, scientific work as such being explicitly excluded, both in the commendation of the statute before its passage and also in the terms of the statute itself.

This clear statutory statement seemingly has stimulated French opinion and led to very eloquent expression of the needs and claims of scientific and inventive workers and the formulation of a scheme of statutory revision of the French law (given in an appendix) by the Union of French Inventors and the French Society of Chemical Industry and others (*La Propriété Industrielle*, 1922, p. 85), and also in the creation and organisation by decree of a National Office of Scientific and Industrial Research and of Inventions.

This paper is of a contentious rather than conclusive character, but if it should suggest any useful consideration of the matter it may not be useless.

Extract from " Proposition de Loi "

Article 1.—Toute nouvelle découverte ou invention, de quelque nature qu'elle soit, confère à son auteur, sous les conditions et pour le temps ci-après déterminé, le droit d'exiger une redevance de tous ceux qui en tirent un profit industriel.

Art. 2.—Si l'auteur de l'invention n'a pas accompli les formalités de l'article 3 de la présente loi, la redevance n'est due qu'à partir du jour de sa demande.

Art. 3.—L'auteur d'une invention ou découverte non susceptible d'être brevetée aux termes des articles 1^er^, 3 et 30 de la loi du 5 juillet, 1844, peut faire constater son droit au moyen d'un brevet de corps ou de principe, délivré dans les conditions du titre II de ladite loi. En ce cas, le droit de la redevance existe à partir du jour de la demande du brevet.

Art. 4.—Le brevet de corps ou de principe ne confère pas à son titulaire le droit exclusif d'exploiter à son profit la découverte ou l'invention, mais seulement le droit de délivrer des licences obligatoires pour l'exploitation de ladite découverte ou invention.

Art. 5.—La propriété scientifique, constatée ou non par brevet, dure pendant toute la vie de l'auteur et, après son décès, 50 ans, dans les conditions prévues par l'article 1^er^ de la loi du 14 juillet, 1866.

Art. 6.—Le taux de la redevance est déterminé par l'accord des parties et à défaut par le tribunal.

Art. 7.—A l'expiration, pour une cause quelconque, du brevet d'invention délivré conformément à la loi du 5 juillet, 1844, l'auteur de l'invention précédemment brevetée reçoit sur sa demande un brevet d'auteur qui lui confère les avantages prévus dans les articles précédents.—(*La Propriété Industrielle*, June 30, 1923, p. 87.)

PASTEUR CENTENARY CELEBRATIONS

From our Special Correspondent

In view of the known dangers of Paris life, the return of Sir William Pope and the other members of the select body of British chemical delegates to the Pasteur celebrations in Paris and Strasbourg, May 23-31, is to be chronicled with satisfaction. The strain of French hospitality has been very great, it appears ; yet such is the strength of the English constitution that it has been able to withstand the test : Paris is poorer, perhaps, by many *demis* but the *ambassade* returns home with the happiest impressions and recollections, satisfied that real service has been rendered in strengthening the rapidly growing bonds of sympathy and friendship uniting French with English chemists.

Commencing on Thursday evening with a most brilliant reception by the President of the Republic at the *Élysée*, the proceedings next day included a visit to the Pasteur Institute and the tomb of Pasteur in its crypt, followed by a crowded meeting, presided over by the President, in the great hall of the Sorbonne—which will seat 5000 persons—at which addresses were presented and much doubtful French was spoken by delegates coming from all over the world. Before this, a most graceful appeal to British sympathies had been made, by unveiling, in the presence of the British delegates, an inscription commemorating the historic meeting of Pasteur and Lister, on December 27, 1892. The British Ambassador, Lord Crewe, made suitable acknowledgment of the compliment. In remembrance of the occasion, the Association "France-Grande Bretagne" gave those present a photograph of the large picture by Rixens representing Lister advancing to embrace Pasteur as the latter arrived upon the platform of the great hall of the Sorbonne. It is worth noting that, amidst the display of academic colour at the Sorbonne cermony, the Chinese delegates were pre-eminent in magnificent most becoming gowns of gold and black.

On the Saturday, a special visit was paid to the *École Normale* and to Pasteur's laboratory there ; on this occasion, a most interesting letter was read, recently discovered in the State Archives, from Pasteur, at an early period of his career, to the Minister of Instruction, pointing out the directions in which inquiry into vital problems might be made with advantage, in striking anticipation of his own later achievements.

In the afternoon, the Municipality of Paris received delegates at the Hotel de Ville. Sunday was devoted to private inquiries, of course of a scientific nature ; but relief was afforded, in the evening, by gala performances at the Opera and the Comédie Francaise. Monday was spent in a visit to Versailles, where a luncheon was given in the great *Salle de Batailles*. On Tuesday afternoon, a visit was paid to Chantilly, not to the Races but to a garden party given by the Institut de France, to whom the Palace with its Art Treasures was bequeathed by the Duc d'Aumale. British chemists were here specially at home, as the party was received by the veteran French chemist, Mons. Haller, the President of the Academy, well known in this country as a visitor to British Association meetings. Visitors were tea'd to the tune of hunting horns in the cyclopean stables in the grounds of the Palace.

Wednesday was spent in travelling to Strasbourg. Thursday there was a full day, commencing with the unveiling of the Pasteur monument by the President of the Republic. Then came a great luncheon ; this was followed by a visit to the Palais du Rhin, to witness a striking march-past of representatives from the surrounding districts in their special costumes, many of great beauty, after which a Pasteur Museum and a Hygienic Exhibition were formally opened, though both were in an embryonic state. At night, the Mayor gave a reception at the Hotel de Ville. Particularly in the evening, Strasbourg was *en fête* and enthusiastic in its reception of the President and especially of Mons. Poincaré, who spoke with admirable effect of Pasteur in the afternoon. Prior to reaching Strasbourg, the President and a select party had visited Dole, Pasteur's birth-place, also several other places with which his name is associated.

Taken generally, the proceedings were very striking and illuminating. They were not without political purpose, especially at the close ; but no such official recognition of the value of scientific effort as the French have given to Pasteur could possibly be made in this country. The press has been full of notices of his life and work. Mons. Millerand and Mons. Poincaré both laid special emphasis, in their speeches, not merely upon the value of his discoveries but upon the great example he had set as a man, by his disinterested and always exact method of working and by his declared devotion to his country. Everything was done, in fact, to bring home to the public the force and truth of the great Frenchman's own words :

> "*Au point où nous sommes arrivés de ce qu'on appelle la civilisation moderne, la culture des sciences dans leur expression la plus élevée est peut-être plus nécessaire encore à l'état moral d'une nation qu'à sa prospérité matérielle.*"

Sunday, May 27, was a Pasteur Flag Day throughout France. In Paris and the suburbs, over 600,000 francs were collected in the streets and theatres. As the day was wet, collections were made again on the following Sunday. The proceeds of the theatres on the 27th are also to be given to the fund, which eventually is to be devoted to French scientific laboratories, for which at present poor provision is made. Noteworthy is the issue of three special Pasteur stamps to mark the celebrations. Clearly, in French opinion, Mons. Millerand was justified in saying :—

"*Si l'on mesure à la valeur et à l'étendue de ses bienfaits la grandeur d'un homme, celui dont nous honorons le centenaire ne le cède à nul autre et le siècle où il a vécu méritera, dans la reconnaissance des générations, de s'appeler : le siècle de Pasteur.*"

As to the monument at Strasbourg, the cost of which is to be met by international subscriptions, the British contribution being £800, the general opinion appears to be that it is a failure and it is to be removed to a less public position than that which it now occupies in face of the University buildings. It may well be compared with the Egyptian monoliths upon which events are recorded in hieroglyphs ; a well-meant attempt has been made, with which scientific workers must sympathise, to represent the outstanding features of Pasteur's career in chronological order upon the four sides of the obelisk, which is of a reddish stone of peculiar hue—commencing with his crystallographic work, typified by a girdle of crystals at the base, terminating with Rabies, typified by dogs. Probably the general public will have as much difficulty in reading the story as the masses in Egypt had, in the past, in interpreting their hieroglyphs ; test-tubes and a 500 c.c. measuring-cylinder graven upon stone are not objects to appeal to the man in the street to-day. Unfortunately the execution, especially of the animal figures, is poor and lacking in expression, the monument itself being squat and of unsatisfying form and proportions. Perhaps the the artist unwittingly pays science a compliment, in being overcome in his attempt to render its victories obvious. To use Pasteur's words :—

"*Il est salutaire de rappeler aux cités qui l'oublient qu'elles ne vivent à travers les âges que par le génie ou la vaillance de quelques-uns de leurs enfants.*"

It is well that we should be reminded how great were his victories by realising how impossible it is to translate them into any ordinary means of expression.

The real value of the visit to most of the delegates probably lay in the opportunities it afforded for private intercourse with French colleagues. The infinite charm of French society is well known—it has a quality and distinction entirely its own. The chemists were peculiarly fortunate in being entertained at a most perfect dinner at the invitation of Dr. Roux and the Pasteur Institute, the evening being under the special charge of the Professors of Chemistry, MM. Bertrand and Fourneau, as Dr. Roux unfortunately was unable to attend. It was certainly the red-letter event of the week and not without special significance. We have to remember that Pasteur was trained as a chemist and achieved his success in virtue of this training —his attitude throughout was that of the chemist. On account of his discovery of molecular asymmetry and his insistence upon the asymmetric character of the phenomena of life, he may well be regarded as the founder of Organic Chemistry proper—the chemistry of life. The day may not be far distant when this is regarded as his prime discovery, certainly that upon which all his later discoveries were based, the key whereby the gates to the now closed passages of life will be unlocked and control no longer permitted to empirical observers. The world awaits a new Pasteur strictly armed with the weapon of scientific method and gifted with the power to use it ; at present we do little more than blunder on in the paths he marked out.

At Strasbourg, the question arose what was the leading industry and at once came the answer : *Foie Gras.* Then followed the question : How would this be placed by the august body in the U.S.A., including the six (unnamed) scientists eminent in the field of Organic Chemistry ? Clearly, it is a *Synthetic Organic Chemical*, under the terms of their Olympian declaration : a *chemical*, since it contains a preponderating quantity of an individual substance ; *organic*, because it contains carbon (obvious if only as truffle) ; *synthetic*, because it is made by a controlled process, not only changed in chemical identity but converted into a material which is not merely a scientific product but a great work of art, which even Mr. Wells's *Men Like Gods* will hold in reverence ; it may even lead to their accumulation in Strasbourg and, let us hope, their extinction by a sudden Rhine flood. That it was to be reckoned among Fine Chemicals, all agreed : no specious Colefaxian rhetoric nor Board of Trade Referee's unreasonable decision can ever rate it otherwise. Another inquiry was undertaken across the Rhine bridge in Kehl, where a Beer garden was discovered without Beer and our delegates had the sensation of their lives in paying 19,000 marks for a more than thin imperial pint of vinous lubricant. A burette, in a shop window, was farcically priced 28,000 marks and there were many other such signs of the depths to which Germans are being brought by the bad faith of those who control their fortunes. The conclusion come to was that the French are probably right in their attempt to force them to behave as if they were gentlemen and meet their obligations.

NOTES FROM HEATHFIELD IV

By the Rector, REV. B. V. WHITE

Dear Mr. Editor,—A few days ago I had the mortification of discovering an omission of which I have been guilty. My wife said to me, " Basil, did you not promise to write an account of our electric lighting ? I have not seen your article in the journal yet." Incited by this and some other observations which followed my answer to the question, I lost no time in preparing this further letter to you.

Here and in the top of Ribblesdale and in some other places in the Dales the hamlets and villages are supplied by electric light by means of power derived from the streams which are very plentiful. Our geological formation includes in these places an alternation of hard and comparatively soft strata which are nearly horizontal; the rivers and streams therefore flow over a succession of these, and as the softer strata wear away quicker than the harder ones the surface of the land tends to become terraced by the outcrops of the harder rocks, and where streams flow over these waterfalls are produced, varying from the noble fall of the Tees at High Force to the graceful one at Hardraw Scar and the many small waterfalls in other places. In my parish we make use of a fall hard by to turn a Pelton wheel or turbine which drives a dynamo and generates an electric current. We store this up in accumulators which consist of a number of plates of lead of which each alternate plate is connected to one wire and the remaining plates are connected to another wire. The plates are covered with a mixture of oxides of lead, the exact composition of which is not easy to specify, for the fine particles which compose the mixture are probably not uniform. The inside of the particle may be one form of oxide and the outside another; thus one may obtain what on chemical analysis appears to be a gradual gradation from lead metal to a dioxide of lead. You may consider some of these as compounds if your fancy so chooses and many of these mixtures have separate names, but to what extent these are definite chemical compounds or merely intimate mixtures with specific physical properties is to me merely a matter of conjecture. But be this as it may, the plates are placed in dilute sulphuric acid and the current from the dynamo passes through from one set of plates to the other. Now there is obviously some sort of equilibrium which will be attained depending on the quantities of the lead, oxygen, water, sulphuric acid and other circumstances. This equilibrium means that certain proportions of lead peroxide, lead sulphate and so on are present, and if you pass an electric current through this accumulator you will tend to form lead peroxide on one plate and metallic lead on the opposite and more free sulphuric acid, and you can do this during the day, and then when night comes disconnect your dynamo and connect the accumulator on to your electric wires, when the sulphuric acid acts on the lead, lead oxides and lead peroxide to form sulphate of lead and water, the plates return to their original state at the same time giving an electric current which flows through the accumulator sufficient to light up the whole village. At about five minutes to ten of the clock the man in charge of the plant disconnects the wires and retires to his rest; this tends to peace and quietness in the whole village. Of course, in the summer it is unnecessary to have any artificial light at all, and indeed on moonlight nights both in the spring and autumn we are able to save the expense of this luxury.

Trinity Bridge

I frequently look forward with considerable animation to the concourse of chemists at Cambridge, where some forty years ago I spent three happy years. Cambridge can never alter; some antique towers may decay and new buildings rise up here and there, but in all its essential features the town itself, the colleges, the life continue the same.

Clare and King's Colleges

Long may it so remain ! For a few years after I went down I kept in touch with the University, read of the discoveries of Liveing and of Dewar, heard of the notable work of Heycock on metallic alloys and rumours reached me of the very ingenious educational methods of Griffith, who had a plan for teaching Divinity which probably is now considered unorthodox. Dewar has gone from us ; a great man, he accomplished much. He was, moreover, a personality, he had force, charm, a love of art and an appreciation of much that is good in this world. Of the work done at Cambridge during recent years, I know little ; long journeys fatigue me more than formerly. Time was when I could take my place at Fenner's, or witch the world with noble horsemanship. But now how things are changed ! My sportive strength is ended, my vaunted strength expended :—

Sir W. J. Pope, K.B.E., F.R.S.

I feel my steep decline ;
The pleasures of my youthful days
Forsake my age, which now betrays
Desire for rest and warmth and wine.

It is some satisfaction that the bracing air of this remote spot in the dales does preserve a good appetite. When I read of the banquet in the Hall of Trinity, my mind went back to my undergraduate days, and I thought of what the poet wrote of the bell which announces the due repast :—

O blessed Bell ! Thou bringest beef and beer,
Thou bringest good things more than tongue may tell.
Seared is, of course, my heart—but unsubdued
Is, and shall be, my appetite for food.

I shall see and hear some distinguished men at Cambridge. Professor Moureu, I know, has worked much on the occurrence of helium in the natural gases and springs. Professors Bancroft and Lewis I know only by name, but years ago I was presented to Monsieur Kestner in Paris, and I have a vague recollection of hearing of the researches of Professor Nasini and Senator Paterno. As to Sir William Pope, I know of his work on optically active substances, on photographic sensitisers and desensitisers, on mustard gas and other subjects, but it would be folly for me to mention facts about him which are far better known to your readers than they are to me. He is a very various man, learned in his own subject, and so far as I can judge from meeting him at the British Association a few times, I should consider him to be a man of the world, shrewd and even worldly in business, and probably able to appreciate that post-prandial refreshment which prevails among the fellows at our ancient seat of learning. Herein he but pursues the same path as the austere Cato—*Narratur et prisci Catonis, Soepe mero caluisse virtus.* Thy fame, O worthy knight, will spread and thy reputation increase

Till Granta's sons from all her sacred bowers
With grateful hand shall weave Pierian flowers
To twine a fragrant chaplet round thy brow.

Professor Lowry I know only from the papers he has contributed to your journal. I think he and I have contributed more articles to it than anyone else ; but I am not sure, for there is one writer who thinly disguises himself under such titles as "Wanderer in Society," "Calorifer," and "Scarifier"—I quote from memory—the name he adopts varies, but there is a pungency, a vigour—what the *Yorkshire Post* calls a Kruschen feeling—about him, if I may use the expression, which marks him for his own. I have almost drop't into his own parenthetical style of writing myself.

My Dear Sir, although I have done such poor justice to the subject, I am able to adorn your pages with some excellent photographs taken by a young friend of mine who has not yet taken Holy Orders.

Ely Cathedral and Norman Monastery

I anticipate a lively pleasure in meeting, for the first time, your distinguished President, your amiable contributor Professor Baly, and your indulgent self, and am, with all respect and kindly wishes, etc., etc.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL MEETING

CAMBRIDGE. JUNE 20 TO 23, 1923

Members intending to be present at the meetings are asked to send in their forms with the appropriate remittance at once, if they have not already done so, in order that the necessary arrangements may be made for them.

Addresses. The title of the President's address to be delivered on Thursday, June 21, is "Chemistry and Industry," and that of Dr. Charles Carpenter's address on the following day is "The Evolution of a Chemical Industry."

Accommodation of Members in Colleges. Accommodation will be available for men in various colleges from the afternoon of Wednesday, June 20, to the afternoon of Saturday, June 23. Members who arrive on Wednesday will be charged an inclusive fee of £3, those arriving on Thursday an inclusive fee of £2. These fees include the use of a set of rooms (bedroom and sitting-room), attendance, gratuities to college servants and the following meals: *Wednesday, June* 20.—Tea (if required) and dinner. *Thursday, June* 21.—Breakfast, lunch and dinner. *Friday, June* 22.—Breakfast, lunch and dinner (if required). *Saturday, June* 23.—Breakfast, and lunch (if required). Members will usually take their breakfasts in their rooms. Luncheon and dinner will be served in the halls of colleges. On Thursday and Friday tea will be served at the Vice-Chancellor's reception, and at the Garden Party at Sidney Sussex College respectively. Members who arrive before five o'clock on Wednesday, and who will require tea, are requested to give notice to that effect on a form to be supplied. There will be no extra charge. Members unable to attend the Annual Dinner of the Society on Friday, and desirous of dining in college that evening, may do so without extra charge by giving notice to that effect on the form above referred to. Members who do not make the trip to Ely, and who require luncheon before leaving Cambridge on Saturday, may obtain it in college on that day without extra charge.

It is important to note that alcoholic drinks are not included in the charges specified above, and members requiring such drinks with their meals must sign a chit presented by the waiter at the time of ordering. Payment for such must be made by members at the office of the Society at the Arts School, Bene't Street, on Saturday, before departure. It is the wish of the college authorities that no money shall change hands at table, and it is hoped that members will kindly co-operate in order that this scheme of payment may be a success.

To the list of colleges offering accommodation given on page 491 of *Chemistry and Industry* of 18th May, Corpus Christi is to be added. As previously stated, men requiring accommodation should communicate with Mr. J. E. G. Harris, the University Chemical Laboratory, Downing Street, Cambridge, who will supply any further information and forward a form to be filled up by the member.

Hotel Accommodation.—The hotels are now more or less full, but there is good accommodation to be obtained in boarding houses (college rooms) should the supply of hotel rooms be exhausted.

The Smoking Concert on June 20 will be held in the dining room of the University Arms Hotel.

Group Photograph. A photograph of the members will be taken at the close of the Annual General Meeting on Thursday, June 21.

Tickets. Tickets for the Smoking Concert, the Reception and Dance, the Annual Dinner, and the excursion to Ely with lunch will be handed to members who have paid the inclusive fee when they register at the office in the Arts School, Bene't Street, Cambridge.

Guide to Cambridge. A copy of the illustrated Guide to Cambridge has been forwarded to each member who has purchased his tickets.

Nominations to Council.—The following have been nominated under By-law 24 to fill four vacancies among the ordinary members of Council: Professor P. Phillips Bedson, Dr. R. T. Colgate, Mr. William Cullen, Professor A. R. Ling, Dr. Joseph Reilly, and Dr. E. W. Smith.

A ballot list has been posted to every member entitled to vote.

J. P. Longstaff,
General Secretary

ADVANCE PROOFS OF PAPERS

Authors of papers which are to be read before local sections or groups, may in some cases desire to have a few advance proofs for distribution among those likely to make useful contributions to the discussion. Any author who requires such advance proofs is requested to hand the manuscript of his paper to the Local Secretary so that it may reach the Editor at least *one month* before the date of the meeting at which it is to be read, in order to allow sufficient time for it to be considered by the Publications Committee and, if approved, set up in type.

ANNUAL REPORTS

Vol. VII. is now ready and can be obtained by members at the price of 7s. 6d., post free, from the offices of the Society.

INSTITUTION OF CHEMICAL ENGINEERS

The first annual corporate meeting of the Institution of Chemical Engineers was held at the Engineers' Club, London, on June 8, under the presidency of Sir Arthur Duckham. In the absence of the hon. secretary (Prof. J. W. Hinchley) through indisposition, the report of the Provisional Council was presented by Mr. C. S. Garland. The report gave a brief account of the formation of the Institution and stated that 205 applications had been received for membership, of which 114 had been accepted by the Council. Mr. W. J. U. Woolcock had been elected the first honorary member of the Institution in recognition of his work on behalf of the chemical industry of this country and especially in the formation of the Institution. The Council had decided that the Institution should take part in the British Empire Exhibition, 1924, and that the sum of £25 should be allocated as a donation towards the chemical section of the Exhibition. The statement of accounts showed the finances of the Institution to be in a sound condition, the liabilities on June 8 being £371, cash at bankers and in hand on the same date being £822.

The President said that although the position was good now, the members would have to know what it was going to cost to run the Institution. So far the work of the Institution had been done largely on a voluntary basis, but henceforth they would have to consider how much assistance they could afford in the future to run the Institution properly. They would have to have definite paid assistance in the form of a Registrar or some person to act as manager of the Institution. The membership of the Institution was, of course, sufficient for the present expenditure, but it was not sufficient to enable them to appoint the type of man they wanted as Registrar.

As the result of a ballot for members of Council the following were declared elected: H. Talbot, J. Arthur Reavell, C. S. Garland, W. B. Davidson, Sir A. Gibb, W. Macnab, Col. Sir F. L. Nathan, J. MacGregor, and W. Newton-Drew. The Associate members of Council elected were R. C. Browning, A. L. Booth and E. C. Randall. The honorary officers were elected as follows: President, Sir Arthur Duckham, K.C.B.; vice-presidents, Dr. C. Carpenter and K. B. Quinan; hon. treasurer, F. H. Rogers; hon. secretary, Prof. J. W. Hinchley.

The President said that Mr. Garland had very generously offered to act as Registrar for the Institution until other arrangements could be made. Mr. Garland had done an enormous amount of work for the Institution since the beginning, he was closely in touch with the work of the Institution, and his assistance would be of the very greatest value. The hearty thanks of the Institution were accorded to Mr. Garland for his offer.

Mr. T. C. Finlayson then read a paper entitled "Industrial Oxygen," an investigation into the possibilities of obtaining cheap oxygen. The author stated that the work had been undertaken under the auspices of Messrs. Woodall-Duckham Vertical Retort and Oven Construction Co. (1920), Ltd., to see if industrial oxygen, which would be of fundamental importance to the gas industry, could be manufactured at a price not exceeding 1s. per 1000 cubic feet, in a plant which would not involve a large capital expenditure.

Starting with a brief review of the various processes which have been invented for the manufacture of oxygen, the speaker subdivided them into: (1) Chemical, (2) physical, and (3) electrolytic processes. It was found that most chemical processes, being conducted at high temperatures, were thermally inefficient, the cost of the oxygen produced being between 7s. and 12s. per 1000 cb. ft. Of the low temperature process the Bergfeld seemed to offer the greatest possibility of producing cheap oxygen, but presented a difficulty in the isolation of oxygen produced when the reaction was reversed.

The physical processes were further subdivided into two groups, viz., solution processes and liquefaction processes. Brief descriptions were given of the Mallet, Helouis, and Belbie processes, which belong to the former group, and fuller descriptions of the Linde, Claude, and Norton processes belonging to the latter section. Here again the cost of oxygen production by liquefaction was very much in excess of the figure aimed at, being with continuous working 19s. per 1000 cb. ft. for small plants and 4s. 6d. per 1000 cb. ft. for large plants. For intermittent working of the plants these figures would be about 27s. per 1000 cb. ft. and 6s. 3d. per 1000 cb. ft., respectively.

Mr. Finlayson then described various cells used in the electrolytic processes and stated that with this type of process the cost of oxygen if the hydrogen was wasted would amount to 56s. per 1000 cb. ft. If, however, both hydrogen and oxygen were utilised the cost would be 28s. per 1000 cb. ft. for oxygen and 14s. per 1000 cb. ft. for hydrogen. Electrolytic processes therefore were only used when small quantities of oxygen were required for certain industrial purposes.

The second part of the paper was devoted to the physical chemistry of metallic oxidation, and of hæmoglobin, the solution of gases in liquids, the adsorption of gases by solid absorbents and the separation of gases by dialysis. As a result of these investigations the author concluded that the adsorption of oxygen by hæmoglobin might give a workable process, but that large plants using hæmoglobin as an adjunct to gas-making would not be considered an attractive proposition. It seemed therefore that cheap oxygen could best be obtained by separation of oxygen and nitrogen by solution methods. With this object in view experimental plant was designed and experiments made on the rate of solution and rate of evolution of air from solutions of water, Diesel Oil, light fuel oil, methylated spirit and paraffin. The effect of agitation and temperature on these rates was also determined. From the information thus obtained a plant capable of producing 1000 cb. ft. of 100 per cent. oxygen per hour was designed. This consisted of two cylindrical vessels each of 660 gallons capacity, provided with an efficient means of agitation and openings for the introduction of air and solvent and the withdrawal of gas and solvent, as well as a device to keep the vessels filled with oil whilst the gas was passing off from the vessel with the stirrer in motion. In working the plant air was pumped into the first cylinder until a pressure of 135 lbs. per sq. in. was attained and then the pressure was raised to 150 lbs. per sq. in. by pumping in blow-back gas. After thorough washing the pressure was allowed to fall rapidly to 75 lbs. per sq. in., the energy contained in this being utilised in driving the high-pressure air blower, after which it passed into the atmosphere. The pressure inside the washer was now allowed to fall to 36 lbs. per sq. in. The gas evolved was used to drive the low-pressure blower during its passage to the atmosphere. During a further fall in pressure to 20 lbs. per sq. in., the gas evolved, containing about 25 per cent. of oxygen, was pumped into washer No. 2, and constituted the "blow-back gas" mentioned above. In this way the oxygen content of the washer was raised to about 22 per cent. The pressure in No. 1 washer was then reduced to 1 lb. absolute when the gas evolved would contain an average of 40 per cent. of oxygen. The results of these experiments made it appear that a supply of 40 per cent. oxygen could possibly be obtained by this pressure-fractionation process more cheaply than by any of the existing methods. As, however, the percentage of oxygen increased, say, to between 60 and 70 per cent., the process became much less efficient. The experimental work showed that ordinary paraffin oil was the best of the solvents tried. Another plant was designed to work under pressures at or below atmospheric. Here the oil was agitated in contact with air at atmospheric pressure and then after saturation the pressure was reduced to 6·5 lbs. per sq. in. absolute, a gas containing an average of 23 per cent. oxygen then being evolved. The pressure was again further reduced to as near zero as possible, when the gas evolved would contain nearly 40 per cent. oxygen. This second method had the advantage over the first in that power was not required for compression, but had the disadvantage that the much larger quantities of oil required give rise to the difficulty of intimate mixing with the air. The saving in power used for compression seemed to be more than counterbalanced by the increased capital outlay and the necessary treatment of much larger quantities of solvents.

The concluding portion of the paper dealt with the uses of oxygen in industry. The author stated that 50 per cent. of the oxygen used in industry was employed in metal cutting, a further 25 per cent. in oxy-acetylene welding, the remainder being used in lead burning and in the production of high temperatures for special purposes. Oxygen has also been used in Germany in the manufacture of nitric and acetic acids, but otherwise its use is not very general in the chemical industry. If cheap oxygen could be obtained and used in the gas industry it probably would not alter materially the carbonisation process, but would, however, permit of a more efficient gasification process being carried out in which both the "run" and the "blow" would give a gas of satisfactory calorific value. By using oxygen in gas manufacture greater internal heat would be generated thus permitting the introduction of more steam, which would make for an increased yield of gas per ton of coal charged. In the author's opinion, whilst the use of oxygen in blast furnace work would be a decided advantage the size and cost of a plant built on the designs outlined above would render its adoption uneconomical.

In the evening, Sir A. Duckham again presided at an informal dinner, which was followed by a short discussion on the training of the chemical engineer. Mr. Donald said that the time has come for some action, and suggested that a committee should be appointed to consider the preparation of a curriculum with the educational authorities of the country. Sir A. Duckham made it clear that the new council considered that one of its first and most important tasks was to confer with the university and other authorities with a view to drawing up an agreed curriculum and he expressed the belief that a scheme of this nature would be ready by the time the next annual meeting was held. During the discussion of the lines upon which training should take place, the sandwich system was recommended by Mr. Garland and severely condemned by several other speakers, and the desirability that British industrialists should assist in training chemical engineers in this country was commented upon. The President first raised the point as arising out of his recent experiences in America, where chemical engineering firms were closely in touch with the teaching institutions and in many cases sent their research work to the institutions to carry out. This or some equivalent method would have to be adopted in this country. Mr. C. S. Garland said that not only would industrialists in this country have to work in close co-operation with the training institutions, but their works managers and others would have to go to the universities and give lectures and say what industry required. Another matter of interest raised was the class of man to be appointed as professors of chemical engineering.

MEETINGS OF OTHER SOCIETIES

SOCIETY OF GLASS TECHNOLOGY

The sixty-second meeting was held in University College, London, on May 16, Prof. W. E. S. Turner, D.Sc., presiding.

Two sessions were held. At the first session two papers were presented. The first, "On the Refractive Index Changes in Optical Glass occasioned by Chilling and Tempering," was by F. Twyman, F.Inst.P., and F. Simeons, B.Sc., F.Inst.P. In presenting this paper Mr. Simeons defined "chilling" as rapid cooling from a high temperature, as opposed to the controlled cooling from a medium temperature known as "annealing." Considerable "chilling" could be effected by allowing glass to cool in air from a temperature within or above the annealing range. In tempering a metal, part of the properties introduced in the preceding operation was removed by heating to a temperature much lower than that attained for "chilling," and allowing the metal to cool slowly. The term "tempering" was applied to the analogous partial recovery of the properties of glass in the annealed state on heating to a medium temperature. "Annealing temperature" was the temperature at which internal stresses existing in a glass were reduced to one-twentieth of their original amount in 0·26 minute. On chilling dense barium crown and borosilicate crown glasses the refractive index might be lowered by as much as 0·004 and 0·0013, respectively. This lowering of refractive index was avoided by heating to a definite temperature and for a definite time.

Mr. V. Stott, B.A., F.Inst.P., then gave a paper entitled, "Notes on Burettes," in which he showed that a burette which emptied rapidly had a very high drainage factor, the draining continuing over a very long period; using a 50 c.c. burette emptying in 20 seconds the drainage was not complete in 30 minutes. But a burette with a long emptying time had a very small drainage, which was practically complete after a comparatively short time. Accurate readings could thus be obtained much more quickly by using a long emptying time and a short drainage, than by using a short emptying time and a correspondingly longer drainage time. Errors due to using a burette calibrated for a certain delivery time with a jet which gave different delivery time were discussed, and it was shown that such errors were, in specified instances, too large to be negligible.

At the second session the President referred to the death of Sir Albert J. Hobson, one of the first members of the Society. He also intimated that the visit to Paris, which had been postponed, would take place some time in July. Two papers were then read. The first was entitled, "A New Method of Glass Melting," by A. Ferguson, who claimed that by means of the method tank bottle-glasses could be melted with 30 tons of coal to 100 t. of glass, including a margin of 60 per cent. safety. The process utilised a cone or column of whirling gases at 1800° C., into the vortex of which batch ground to 60-mesh was dribbled at the rate of two lb. per second, the carbon dioxide of the limespar and soda having been first driven off in a preheater so that the furnace had only to raise the temperature from 850° to 1350° instead of from 20° C. The particles of finely divided batch exposed to the heat a surface which was over 6000 times that of batch "spread on" and the permeation of the particles was 2000 times easier. All reactions necessary to form glass molecules took place in a gas at least two million times less viscous than tank metal, so that affinities could reach each other, collide and react millions of times per second, instead of all the energy of the atom being required for hours to find the waiting affinity somewhere in a tank, and when not encountered resulting in seed, striæ and unequal strain in the glass. All preheating was done by waste heat; the coal was retorted, the hydrocarbons saved, air and batch preheated and freed from carbon dioxide. The process was entirely automatic from coal and batch bin to warehouse counter. The batch, instantly melted and refined, flowed through a stream-line tank to a periphery gatherer in a firehearth.

The second paper was entitled, "Natural Sillimanite as a Glass Refractory," by S. English, M.Sc., who gave results of tests, which showed that this material possessed properties of great value to glass makers. Test pieces were made up by mixing 100 parts of sieved sillimanite with 10 parts of finely ground clay; such a mixture could be made into slabs and pressed into crucibles if care were taken in working it. These slabs and crucibles were examined for the properties which were the chief causes of trouble to glass makers when using ordinary clay refractories, and the results showed:—(1) The drying and firing shrinkages of the sillimanite mixture were very much less than the corresponding contractions of pot-clay mixtures, in fact sillimanite slabs that were completely air-dried showed practically no further shrinkage on firing to 1400°. (2) The porosity of the fired sillimanite slabs was rather less than the porosity of pot-clay slabs fired to the same temperature. (3) Sillimanite crucibles were attacked very much less by molten glass at 1400—1420° C. than were similar size pot-clay crucibles.

In the evening the annual dinner was held in the Hotel Cecil, the president being in the chair. Among those present were Sir F. W. Dyson, F.R.S., Astronomer Royal; H. J. C. Johnston, Esq., President of the Institute of Clayworkers; Frank Wood, C.B.E., B.Sc., and Dr. M. W. Travers, F.R.S., past presidents of the Society; A. R. Upjohn, Esq., LL.B., Master of the Glaziers' Company; R. L. Frink, Director of the Glass Research Association; and Mons. Courty, of Paris.

CHEMICAL SOCIETY

A formidable array of papers was announced for presentation at the meeting of the Chemical Society on June 7. Prof. Wynne presided, each of the seven papers on the list being dealt with.

(1) "Investigations on the dependence of rotatory power on chemical constitution. Part XX. The rational study of optical properties: Refraction a constitutive property," by H. Hunter. Dr. R. H. Pickard, F.R.S., who communicated the paper on behalf of the author, pointed out the aim of following up refractive dispersion so as to connect it with rotatory dispersion. The Pulfrich refractometer was used for measurement and even with this accurate instrument reliability could only be taken to the fourth decimal place, whereas in the literature on the subject it was quite usual to record the fifth place. Refraction was largely constitutive—*e.g.*, using Eisenhohe's recalculation of Conradi's figures for atomic refractivities it was necessary to ascribe to oxygen six different values.

(2) "Researches on indium. Part I. Diphenyl indium chloride and phenyl indium oxide," by A. E. Goddard. It was stated that indium formed compounds similar to thallium of the types R_2InCl and $RInO$. The compounds discussed were those in which the radical R was phenyl. These were obtained as powders.

(3) "The properties of ammonium nitrate. Part VI. The reciprocal salt pair, ammonium nitrate and potassium sulphate," by E. P. Perman and W. J. Howells. Dr. Perman submitted curves showing the formation of compounds, mixtures and mixed crystals when ammonium nitrate and potassium sulphate were the components.

(4) "Ring-chain tautomerism. Part VI. The mechanism of the keto-cyclol change in the propane series," by E. W. Lanfear and J. F. Thorpe. Prof. Thorpe showed how stability was conferred on one or other of the two tautomeric forms each with the wandering hydrogen atom—*i.e.*, the keto acid or the hydroxy-ring acid by different kinds of substitution or alteration, on his hypothesis of the tetrahedral angle.

It would be of interest to correlate or contrast Prof. Thorpe's view of tautomeric change with those of G. N. Lewis based on the arrangement of electrons within the various molecules.

The other papers were:—

(5) "The reversibility of additive reactions. Part I. The aldol reaction," by E. H. Usherwood.

(6) Mechanism of the pinacone-pinacoline and Wagner-Meerwein transformations," by C. K. Ingold.

(7) "Researches on antimony. Part I. Tri-*m*-xylylstibene and its derivatives," by A. E. Goddard.

PHYSICAL SOCIETY

At the meeting held on May 25 at the Imperial College of Science, Dr. A. Russell, M.A., in the chair, a paper on "The Effect of Torsion on the Thermal and Electric Conductivities of Metals," by Prof. C. H. Lees, F.R.S., and J. E. Calthrop, B.A., B.Sc., was read by Prof. Lees. A method was described which enabled measurement to be made of the effect of twisting a wire on its thermal conductivity. In each of the steel, aluminium, copper, and lead wires tested the twist decreased the conductivity along the wire by a small amount, approximately proportional to the square of the twist per unit length. The change of electrical conductivity was found to be in general less than the change of thermal conductivity, but was also approximately proportional to the square of the twist per unit length. In reply to the discussion, Prof. Lees said the wires were soft and not annealed; the object of the experiments was to test the electron theory of conduction.

Mr. C. R. Darling, F.Inst.P., F.I.C., read a paper entitled "An Experiment on the Production of an Intermittent Pressure by Boiling Water." If a glass tube, open at both ends, and of about 5 mm. bore, were placed in a beaker of briskly boiling water so as to rest on the bottom of the beaker, steam bubbles would form at the point of contact, causing the water to rise to a definite height in the tube. The column of water thus raised sunk after a time and then rose again, the rising and falling occurred at regular intervals. If the tube were narrowed to a bore of about 1 mm. near the top of the water, and widened out considerably just above the water surface, the phenomenon then became regular in action. After rising to the height of about 3 cm. in the widened part, the water discharged back into the beaker, and after a short interval again rose and was discharged, the cycle being repeated indefinitely. The water was apparently superheated at the points of contact of the tube and beaker, so that the steam produced could sustain a higher pressure of water. When the water reached the widened part, however, it was cooled and increased in density until the extra steam pressure at the bottom of the tube was overcome, when it discharged completely. The capillary bore slowed down the rate of flow in both directions, and thus steadied the movements.

Dr. F. E. Breithut has been appointed Chemical Trade Commissioner on the staff of the United States Commercial Attachée at Berlin. Dr. Breithut was attached to the United States Chemical Warfare Service and later has been engaged in industrial chemical work. He is a member of this and other societies.

PERSONALIA

Professor H. Louis, D.Sc., has been appointed a member of the Royal Commission on subsidence caused by mining operations, of which the Right Hon. the Viscount Chelmsford is chairman.

At a recent meeting of the Court of the Leeds University it was decided to confer the honorary degree of Doctor of Literature on Sir E. Brotherton, Bart., and of Doctor of Science on Professor A. Smithells.

Sir R. Hadfield, F.R.S., has been elected a corresponding member of the Académie des Sciences, Paris.

Dr. E. P. Hyde has resigned from the directorate of research of the National Lamp Works of the General Electric Co., U.S.A.

Dr. W. A. Caldecott, industrial adviser and metallurgist to the New Consolidated Goldfields, Ltd., has accepted the post of Director of Industries in the Department of Mines and Industries, South Africa.

Monsieur Richard, professor of chemistry at the University of Bordeaux, has been appointed Director of the School of Chemistry of that University, in place of the late Prof. Dubourg.

Prof. J. R. Withrow has been nominated Chairman of the United States National Research Council Committee on the use of sodium compounds as substitutes for potassium compounds in scientific and industrial work.

Monsieur H. Gabelle, Director of the Conservatoire National des Arts et Métiers at Paris, has been confirmed in his post for a further eight years.

Messrs. J. H. T. Roberts, J. H. G. Monypenny, R. C. Richards and G. C. Simpson have been elected Fellows of the Institute of Physics, and Messrs. A. Adderley, W. T. Astbury, F. G. C. Bratt, P. A. Curry, G. A. R. Foster, A. E. Owen and J. H. Smith have been elected Associates.

Mr. H. M. Lancaster, who is an active member of the Canadian Section of the Society of Chemical Industry, has been appointed Director of the Laboratories of the Dominion Department of Health, Canada.

Major B. J. Eaton, O.B.E., Agricultural Chemist of the Federated Malay States, has been selected to represent the Governments of the Federated Malay States and Straits Settlements (British Malaya) at the Pan Pacific Scientific Congress to be held in Sydney and Melbourne from August 13 to September 3, 1923.

Dr. E. W. Schwartze, of the U.S. Bureau of Chemistry, has received a Fellowship from the National Research Council for a year's study in the laboratory of Sir W. M. Bayliss in University College, London.

From the United States the death is announced of E. C. Klipstein, a member of the firm of that name which was the first to market sulphur black and to manufacture synthetic tannins in the United States. Mr. Klipstein, who was a well-known authority in textile and leather chemistry, has been a member of this Society since 1902.

The death is announced of Prof. P. N. Arata, a well-known Argentine pharmacist and professor of chemistry in the University of Buenos Ayres. Prof. Arata was the founder of the Argentine National Chemical Bureau, and the author of numerous technical treatises.

From Germany the death is announced of Dr. F. Isernhehn, chemist of F. Bayer and Co., of Leverkusen.

FORTHCOMING EVENTS

June 16.	The Royal Institution of Great Britain. at 3 p.m. "Atomic Projectiles and their Properties," by Sir E. Rutherford.
June 16.	Society of Chemical Industry, *Edinburgh and East of Scotland Section.* Excursion to Melrose and Abbotsford, leaving Edinburgh at 1.30 p.m.
June 16 to 20.	Meeting of the Union Internationale de la Chimie Pure et Appliquée at Cambridge.
June 20 to 23.	Society of Chemical Industry. Annual meeting at Cambridge.
June 21.	The Royal Society. The Croonian Lecture will be delivered at Burlington House, Piccadilly, W. 1, at 4.30 p.m.. on "Plant Respiration as a Catalytic Process," by Dr. F. F. Blackman, F.R.S.
June 21.	The Chemical Society, Burlington House, Piccadilly, W. 1. Ordinary Scientific Meeting at 8 p.m. (1) "The Constitution of the Higher Oxide of Nickel," by O. R. Howell; (2) "The Relationship of the Tautomeric Hydrogen Theory to the Theory of Induced Alternate Polarities," by F. Allsop and J. Kenner. (3) "Electron Valency Theories and Stereochemistry," by S. Sugden. (4) "The Relative Influences of Water Vapour and Hydrogen upon the Combustion of Carbon Monoxide—Air Mixtures at High Temperatures," by W. A. Bone, D. M. Newitt, D. T. A. Townend. (5) "Metallic Hydroxy-Acid Complexes. Part I. Cuprilactates," by I. W. Wark. (6) "Metallic Hydroxy-Acid Complexes, Part II. Cuprimalates, their Formation, Properties and Composition," by I. W. Wark. (7) "Cholesterol and its Role in the Organism," by S. Minovici.
June 28.	The Institution of Electrical Engineers. The annual conversazione will be held at the Natural History Museum, South Kensington, S.W., at 8.30 p.m.

CORRESPONDENCE

A BURNING QUESTION AND A CONTENTIOUS BONE

SIR,—Nine-tenths of the luciferous letter in your issue of June 8 is pure bluff, the rest merely specious, loose logic. To deal with the complex issues of combustion with levity is useless waste of your space and a bad example to your sensitive readers. It is not the treatment I should have expected from one bred in the bosom of a stern faith. My mentor has named himself with unconscious humour. I asked for light, not for darkness. It were meet that I keep company with angels, not walk out with the fallen, as my friends imply that the partial pressure of my respectability is low, whatever its differential coefficient, particularly that my hydrogen-ion-concentration should on no account be raised.

To make experiments is an easy task to many; to make use of the results is beyond most. That this is so is clear from the fact that, from Davy onwards, we have an endless series of observations but are still without the vestige of an acknowledged "theory" of the process of combustion in our text-books. Nevertheless, we rate ourselves scientific—in reality, we just muddle through, like ordinary people; yet should we be careful that our conceit be not found out ere long The funds for research work must soon come to an end, if we do not now experiment with clear purpose and greater effect than heretofore: only to this end can the use of public money be justified.

The dispute between Lucifer and me hinges upon the interpretation of the difference between a hydrogen-air and a carbonic-oxide-air mixture. Lucifer has upon his brain the "activation" of nitrogen by some mysterious, sympathetic vibration process: he regards it as a mere carbonic oxide buffer which takes up the shock; I would leave all such speculation to the Liverpool School and remain true to what is called by Jacques Loeb "classical chemistry" —a discipline little favoured by the luciferous school, it seems. Writing in Derby week, I may say shortly that I am backing Nitric Oxide.

Says Lucifer :—

> Doubtless a part of the "activated" nitrogen primarily formed in our CO-air explosions at high pressures was oxidised in some experiments to nitric oxide, especially when more oxygen was present than sufficed to burn all the carbon monoxide. But an analysis of the actual pressure curves has shown that any such nitric oxide formation was a secondary effect, and that the results as a whole cannot be explained except on the supposition that the lag was primarily due to "activation" of nitrogen itself. Besides which, even were the "nitric oxide" supposition to be preferable to that of "nitrogen activation" (which it is not), it would still be necessary to explain (*a*) why the said lag was never observed in our hydrogen-air explosions, and (*b*) in the case of our CO-air explosions why the replacement of a small part only of the carbon-monoxide by its equivalent of hydrogen removed it.

To which I reply: (1) There is not the slightest proof that any special form of "activated nitrogen" is primarily formed or reason to suppose that it ever is: everything becomes "active" at high temperatures. (2) As to the analysis—what analysis? I fail to find any in the Royal Society paper, after reading this carefully several times. How any analysis can show that the formation of nitric oxide was a secondary effect, I fail to see; nor that the lag cannot be explained except on the supposition of an activated nitrogen. (3) As to the (*a*) and (*b*) besides, Lucifer fails to realise that in hydrogen alone and even in presence of a small proportion of the gas the conditions are entirely different from those in carbonic oxide. In presence of the large amount of moisture formed—I will not harrow his majesty's feelings by writing the melodious, well-formed word I would substitute for it—the rate of change would be much more rapid than in the simple carbonic oxide mixture. As an appreciable amount of nitric oxide is present in the cold gases, the proportion formed at a high temperature may be very considerable, and this would revert but slowly in the dry atmosphere; in the wet hydrogen atmosphere, possibly there would be less nitric oxide formed initially and what was formed would be more readily unburnt, so that little would persist.

I do not think I have missed any point in the argument, let alone a cardinal one.

There is nothing new in the observation that nitric oxide is produced in gaseous explosions—I fancy a chapter is devoted to the subject in the Government Nitrogen Report. Those of us who are interested in such matters have long had the problem under notice. As to the effect of living with a bomb—familiarity has been known to breed contempt. I am not so anxious for more inquiry as I am for light on the records already before us. Messrs. Bone and Co. have given us a long series of trustworthy data, but it may well happen that the reapers will be other than the sowers; in any case the harvest is yet to be properly garnered.

CALORIFER

P.S.—The behaviour of nitrated explosives is worth noticing in connexion with the question at issue. They may be regarded as potentially nitric oxide personified, yet the gas is scarcely present in the products, even when they are exploded under conditions giving rise to very high pressures and presumably correspondingly high temperatures. Doubtless it is all "over burnt." Reference may be recommended to Sir R. Robertson's recent Royal Society paper. It is very kind of Mr. Finch to tell me of his visit to South Kensington. If it becomes the fashion for visitors to laboratories to deliver such *obiter dicta*, you will have no need to invite scientific communications to your columns, and your *Journal* will be quite a chatty organ. I already hear it spoken of as "readable." In time we may learn the quality of the afternoon teas—now a want felt with great regularity in all laboratories—and so be able to make our selection among them. As to his conclusions: *b* is a self-evident proposition, *a*, *c* and *d* are just assertions, such deductions are not to be made from any scrutiny of continuous curves, which merely show rise and fall of pressure. They are but the dictated interpretations of Lucifer.

GOLD OUTPUT IN WESTERN AUSTRALIA

Sir,—I beg to advise you that the Honourable the Premier of Western Australia draws attention to a paragraph on page 242 of *Chemistry and Industry* of March 9, which purports to give particulars of the gold production in Australia for the year 1922.

The figures given in the *Board of Trade Journal* of March 1, 1923, page 274, from which your paragraph is taken, relate to the State of New South Wales only. The output for the *whole* of Australia for 1921 was 767,194 fine ounces, valued at £3,258,832, and for that year the output for Western Australia was 553,731 fine ounces, valued at £2,352,098. For the year 1922 the output for Western Australia was 538,246 fine ounces, valued at £2,286,325, but I have not the complete figures for the other States.

The Agent-General will be glad if you will make the necessary correction in the next issue of your Journal.—I am, Sir, etc.,

C. B. Bannister,
Secretary to the Agent-General
for Western Australia
Savoy House, W.C. 2
June 7, 1923

THE ORIGIN OF TWADDELL'S HYDROMETER

Sir,—Mr. H. A. Auden's letter on the above subject, which appeared in the issue for May 18 last, does not seem to have elicited any response, so perhaps the few notes upon the genesis of the instrument which follow may be of value.

In the memoir of Charles Macintosh, of india-rubber fame, compiled by his son George Macintosh (privately printed in Glasgow, 1847), there is given a list of the inventions to which Mr. Macintosh laid claim, one of these being the improved Baumé's hydrometer, and on page 49 of the same memoir it is stated that: "Mr. Macintosh was also the inventor of the hydrometer or aerometer which has been named Twaddel's hydrometer, from the last-named mechanician having constructed them according to Mr. Macintosh's directions. This instrument was first used for the purpose of determining the specific gravity of the alum liquors, and seems to have been a modification of the hydrometer of Fahrenheit (or rather of Baumé)." The date of this invention was about the year 1809, when Macintosh was busy with the manufacture of alum from shale near Glasgow.

In 1805, Wm. Twaddel, described as a "Glass-spirit proof maker," had a shop at 76, Saltmarket, in Glasgow. In 1810 he had removed to the High Street of that city, and he carried on his business at various addresses until 1839-40, when his name disappears from the directory, and in 1840-41 is succeeded by Thomas Twaddell (with two l's) at his last address, and shortly after the name becomes Thomas Twaddell and Co., and so continues for some years. What relation Thomas Twaddell was to William Twaddel is not evident, perhaps son or nephew, but it is clear that William Twaddel was the maker (but not the inventor) of the instrument known by his name; regarding the spelling of the name there is ground for spelling it either with one "l" or with two, but the earlier form has only one, and is, I think, to be preferred. The Tyneside story of the origin of the instrument is, I make bold to say, a pure myth.—I am, Sir, etc.,

BRITISH CHEMISTRY AND GERMAN PUBLICATIONS

Sir,—With reference to some remarks in last week's editorial of *Chemistry and Industry*, that some doubt has been felt as to the reason why references to the work of British chemists have been left out in many of the recent German publications, may I, as one who recently had the opportunity of mixing and speaking with quite a number of research workers in Germany, give my impressions in this matter?

Nowadays it is absolutely impossible for a German chemist to subscribe to any foreign journal. The pay of the highest paid professors a couple of months ago was four pounds monthly at the then exchange rate.

Only very few libraries can now afford to take in foreign papers; even the biggest Universities in Germany have been forced to stop their subscriptions to almost all foreign periodicals, because the value of the mark is so low.

With the exception of Austrian publications and occasional gifts of stray numbers of Scandinavian and Dutch journals, hardly any other scientific papers reach the German Universities.

When I was in Germany last time more than a dozen people went to the extent of copying down the whole of the British journals I received. Even then the expense of buying sheets of writing-paper for this purpose was considered as a very heavy one!

I hope you will agree with me that the reason for which recent work of British as well as other foreign chemists is not acknowledged is surely not one of deliberate intention; it is the desperate economic situation which has prevented the majority of the German chemists from getting at the foreign literature. What seems to me most surprising is that there can be any scientific work done in Germany of to-day—the conditions there are appalling.—I am, Sir, etc.,

THE "STREAM-LINE" FILTER

Sir,—At the last meeting of the London Section of the Society of Chemical Industry, Prof. Hele-Shaw gave an exceedingly attractive demonstration and interesting paper on his new "Stream-line Filter."

The experiments and description of the working of the filter raised hopes for its successful application in varied fields of industry and research—*e.g.*, in colloidal chemistry, biochemistry, bacteriology, etc. It is therefore rather surprising that figures, apart from the rate of filtration, have not been given to indicate its capabilities. As the strength of a chain is that of its weakest link, so one factor of the efficiency of a filter is the size of the smallest particle it will with certainty retain or separate from the liquid to be filtered. The only definite statement of measure, apart from the experiments shown with coloured liquids, was that the filter was capable of retaining or separating particles that were small enough to pass through the best analytical filter paper. There are, however, numerous ultra-filters made from solutions of collodion of different concentration or of collodion with other substances which can be made to effect varying degrees of filtration, and by comparison it ought not to be difficult to state the capabilities of the new filter in terms of μ or $\mu\mu$.

The way the filter works seems to be all-important for future development. Is the selective filtration the same under similar conditions of pressure, etc., when different liquids are used as the dispersion medium? How does the filter behave with dialysed ferric hydroxide, congo red, night blue, etc.? Is the mechanism in the case of colloids really one of filtration or straining (the word "filter" being akin to felt), or does it bring about separation by adsorption of the disperse phase?

One is led to inquire whether measurements have been made in differences of electrical potential.

Lastly, the paper used appears to be made from un-treated or partially treated wood pulp, and yet it is claimed as waterproof. How does its composition, especially its inorganic constituents, affect the working? Is there any possibility of ignition when volatile liquids of low flash-point are filtered?—I am, Sir, etc.,

W. H. Patterson

University of London Club

NEWS AND NOTES

UNITED STATES

Phosphate Rock in 1921

The phosphate rock industry was very depressed during 1921, probably owing to over-production in the previous year, and sales declined by nearly 50 per cent. in quantity and 50 per cent. in value to 2,064,025 long tons valued at $12,270,070. Production ceased entirely in S. Carolina, fell by 90 per cent. in the Western States, by nearly one-half in Tennessee and Kentucky, and more than one-third in Florida. Exports of phosphate rock fell from 31,461 t. in 1920 to 6,293 t. in 1921.

FRANCE

Mineral Output in 1922

Provisional figures for the production of minerals in France during 1922 are given in the following table:—

	1922 Metric tons
Salt	1,048,614
Potash:—	
Crude salts (12 to 16% K_2O)	320,975
Fertilising salts (20 to 22% K_2O)	337,318
Fertilising salts (30 to 40% K_2O)	59,608
Potassium chloride (over 50% K_2O)	126,866
Total contents of K_2O	207,123
Mineral oil	63,377
Asphalt	37,320
Bauxite	139,176
Iron pyrites	175,066
Ores:—	
Antimony	3,280
Arsenic	941
Gold-bearing	46,175
Copper	364
Iron ore	20,831,993
Lead	10,470
Zinc	2,404
Manganese	684

GENERAL

The Isotopes of Germanium

In a letter to *Nature* of June 9, Dr. F. W. Aston announces that, using the improved method of accelerated anode rays, he has succeeded in obtaining the mass-spectrum of germanium. The effects were feeble, but satisfactory evidence of three isotopes was obtained. Their mass-lines were at 70, 72 and 74, and appeared to be whole numbers, though the accuracy of measurement was not as high as usual. The intensities were roughly in the proportion of 2 : 4 : 5, which agreed reasonably well with the value 72·5 for the chemical atomic weight now in use. Dr. F. W. Aston further pointed out that these values conformed to the general rule connecting even atomic number with even atomic weight, and that it appears that Ge^{70} is isobaric with the weakest and heaviest component of zinc discovered by Dempster, and Ge^{74} isobaric with the lightest and weakest isotopes of selenium announced in 1922 in *Nature* (Nov. 18, p. 664).

The Output of Copper Sulphate in Italy

Italy, which is the chief consumer of copper sulphate, is also an important producer, the production amounting to 75,000 metric tons, which is in excess of the requirements, and compares with an output of 50,000 t. in 1918 and 20,000 t. in 1914. The factories that produce copper sulphate are scattered throughout the country, but are most numerous in the North.—(*U.S. Comm. Rep., Apr.* 23, 1923.)

Bulgarian Beet-sugar Crop

H.M. Commercial Secretary, Sofia, states that the Bulgarian beet crop in 1922 was 100,000 tons, which yielded 15,000 tons of sugar. This amount is insufficient to meet local requirements, estimated at 35,000 to 45,000 tons per annum, and the balance required is imported from Czechoslovakia, Germany and the United States. For the sugar factories to work at full capacity at least 250,000 hectares (hectare = 2·47 acres) should be cultivated with beet, whereas in 1922 only 90,000 hectares was under the crop.—(*Bd. of Trade J., Apr.* 19, 1923.)

The Greek Emery Industry

It is reported that the Greek Government has decided to construct works at Naxos, at a cost of £30,000, to facilitate the mining and transport of emery ore. The works will, it is estimated, be complete within a year and should result in increasing the annual production to roughly 20,000 tons.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for June* 7)

TARIFF CUSTOMS EXCISE

Australia.—A dumping duty has been levied on aluminium and enamelled ware, various industrial and pharmaceutical chemicals and certain glass apparatus of German and Czechoslovakian origin.

Bolivia.—The export duty on silver has now been cancelled. The importation of alcohol has been prohibited.

British India.—A revised export duty has been applied to raw hides and skins.

Cyprus.—The import duty on matches has been revised.

Egypt.—Sugar is now free from excise duty.

New Zealand.—The embargo on the importation of German and Austrian goods is to be discontinued.

Poland.—A translation is given of a list of goods which are subject to a surtax of 899,900 per cent. All goods that are not included in this list are subject to a surtax of 599,900 per cent.

South Africa.—The Food, Drugs and Disinfectants Bill has been postponed.

South Africa (*Cape of Good Hope*).—Notice is given of standards regulating the content of milk solids and of preservatives in milk and foodstuffs.

Sweden.—Bills have been passed to raise the malt tax, regulate the manufacture, sale and importation of beer and increase the duty on malt. The regulations regarding the control of platinum wares have also been revised.

Tanganyika.—Restrictions have been placed upon the importation of opium, morphine, heroin, cocaine, and articles containing such drugs.

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Stoneware, cast-iron pipes	7425/F.L./E.C./2
Australia	Brass and copper sheets and rods	712
Austria, Hungary, Czecho-slovakia	Chemicals, drugs, tanning materials, oils, fats	718
Canada	Paint	715
”	Scrap leather	11361/E.D./M.C.
France	Oils, fats, acid oils, tinplate, copper sulphate	722
Germany	Waste fats	F.W. 18905
Greece	Pharmaceutical products	726
Netherlands	Corrugated and galvanised sheets, pickled plates, lead foil, forgings	728, 731, 732
Panama	Paper	745
Poland	Glass, glassware	225/78/F.G./M.C.
United States	Pottery	742

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Dried Milk

Lord E. Percy informed Mr. Lamb that regulations were under consideration to provide for the proper labelling of dried milks.—(May 31.)

Dyestuffs

Viscount Wolmer, replying to Mr. Darbishire, said he had no reason to suppose that the high prices of dyestuffs in this country were the main cause of British goods being sent abroad to be dyed. In cases when licences to import foreign dyestuffs had been refused the Licensing Committee had no doubt given full weight to all relevant considerations. As regards the allegation that on many occasions the prices of reparation dyes exceeded the prices at which they could be obtained from Germany under licence, an Advisory Committee on prices had been formed, two of the four members representing the Colour-Users' Association.—(June 4.)

Sir P. Lloyd-Greame, replying to Mr. H. H. Spencer, said he was aware that the export of grey cotton cloth increased by 50 per cent., and that of printed and coloured woven cloth decreased by 38 per cent. in 1922 as compared with 1920. He did not agree that this was due mainly to the prices of dyestuffs. But for the action taken to promote the dye-making industry, the British textile trades would now be very greatly embarrassed.—(June 5.)

Patent Fees

Replying to Mr. Hannon, Sir P. Lloyd-Greame said that although British patents covering a population of about 45,000,000, cost £131 in fees for 16 years, and that patents in the United States covering a population of 110,000,000 for 17 years cost only about £7 10s., there was no fair basis of comparison between these fees owing to differences in the permissible scope of single patents and other considerations. It was not practicable to reduce the British fees at present.—(June 5.)

Carbon Monoxide in Gas

Answering various questions Sir P. Lloyd-Greame said that he was informed that the gas produced by the Tully plant contained 37 per cent. of carbon monoxide, but it was claimed that by means of a new converter, the carbon monoxide contained could be reduced to a negligible quantity. The matter was being carefully watched by the Government departments concerned.—(June 5.)

Safeguarding of Industries Act

In a written answer Sir P. Lloyd-Greame informed Mr. Hannon that the basis on which depreciated currency duty was levied under the Safeguarding of Industries Act was defined in the Act, and could not be varied in accordance with the tariff system in operation in Spain and other countries without legislation.—(June 5.)

Replying to Major Entwistle, Sir P. Lloyd-Greame said that the export from Germany to this country of fabric gloves, enamel, aluminium, gas mantles, and glassware was controlled, but he could not confirm the statement that invoices in sterling were insisted upon. H.M. Customs, however, required an invoice in sterling.—(June 7.)

REVIEWS

LEHRBUCH DER CHEMIE. *By* PROF. MAX TRAUTZ. VOL. I. STOFFE. *Pp. xxviii*+534. *Berlin and Leipzig: Vereinigung Wissenschaftlicher Verleger,* 1922. *Price* 22*s.* 6*d.*

This is Volume I. of an attempt to treat the whole of chemistry in three volumes, in such a way as to give the student of chemistry the real essentials of the subject, and the connexion between it and related subjects (physics, mathematics, etc.), without demanding any considerable previous knowledge.

The present volume deals with Stoichiometry, Electrochemistry and Thermochemistry. The arrangement of the numerous sub-divisions of these main branches in the table of contents is somewhat difficult to follow.

Stoichiometry occupies 236 pages and in its first sub-section (" Quantity of Matter," 10 pp.), deals with the definition of mass, its measurement by weighing, the precautions which must be observed in accurate weighing and a discussion of the Law of the Conservation of Mass. The second sub-section (50 pp.) is entitled, " Homogeneity and Volume of Matter," and includes a short discussion of the nature of pure substances and mixtures and the methods of separating the constituents of mixtures, a brief introduction to the molecular theory, the gas laws and Avogadro's law. Then follows an introduction to preparative chemistry in which the preparation and properties of oxygen, hydrogen and water are briefly described, and the nature of aqueous solutions is indicated. The laws of combination and the methods of determining atomic weights are then discussed, brief mention being made of such subjects as isotopes, the absolute size and mass of atoms and molecules, and Avogadro's number. The third sub-section (" Kinds of Matter and the Multiplicity of its Compounds," 168 pp.), treats of the atmosphere and its constituents; ozone and the halogens (in connexion with their occurrence in the atmosphere); metals and non-metals, crystallography; non-metallic elements according to their groups in the periodic system; valency; then, according to groups in the periodic system, the hydrides, oxides, hydroxides, oxygen acids, sulphides, hydrosulphides, halogen compounds, azides and cyanides of the elements. Then follows a collection of the more important metallic salts of the oxygen acids, arranged according to the groups of metals in the periodic system.

In Electrochemistry, Part I., 20 pages are occupied in explaining the fundamental laws of electricity, 40 pages in dealing with the elements of electrochemistry and 10 pages are devoted to a discussion of complex salts. This is followed by analytical and preparative electrochemistry (52 pp.). In the former, volumetric analysis, electroanalysis and qualitative analysis are dealt with, whilst the latter treats briefly of the technical preparation of metals, alkalis, salts, halogens, etc. by electrolysis.

Part III., Thermochemistry, (130 pp.), discusses the laws of thermodynamics and their application to chemical and electrochemical processes (56 pp.). The remainder of the book discusses the production and application of high temperatures, including such varied topics as qualitative dry tests, gaseous liquid and solid fuels, and electrical heating; the preparation of substances by electrothermic methods; the Goldschmidt processes; metallurgy; glass and ceramics; and a host of miscellaneous preparations and descriptions of furnaces.

It is difficult to imagine the type of student for whom this book is intended. Certainly it is not suitable for the British student. Even as a work of reference its scope is limited by the meagre treatment of important substances in systematic chemistry, a treatment which is no fuller and in many cases not so full as in our own best text-books. The lack of references to original literature also rules it out for this purpose. The arrangement, too, is difficult to follow and the student who tries to teach himself chemistry with the help of this volume will probably find himself suffering from a severe attack of chemical indigestion.

Much of the matter is well done, expecially the physico-chemical part, but even this is spoiled by unnecessary introductions, physical and mathematical. Everything is worked up from the very beginnings, and the reader is evidently presumed to have no previous knowledge of either physics or chemistry.

Many of the very numerous illustrations are quite unnecessary, such as the various catalogue pictures of the commonest pieces of apparatus —even a spatula is represented. Pages 124 to 127 are mainly taken up with diagrams of the various varieties of Gæde pumps, with no word of explanation in the letterpress, and similar instances are not lacking. The book is provided with a good index—and it is needed.

Joseph Knox

The Destructive Distillation of Wood. *By* H. M. Bunbury, M.Sc. *Pp. xx*+320. *London: Benn Brothers, Ltd.*, 1923. *Price* 35*s*.

It is a curious fact that, in spite of the importance of the wood-distillation industry in America and Canada, no text-book on the subject has appeared hitherto from the pen of an English or American author. For a comparatively long period about one-half the world's supply of wood-distillation products has been derived from America, but scientific investigations on the nature of the process, as well as refinements in the design of the necessary plant, are largely of German, French and Scandinavian origin; in fact, it is only in the last decade that any considerable volume of literature, chiefly in the form of contributions to scientific journals, Forest Service Bulletins, etc., has appeared from American sources. In Great Britain the recent rise of the industry from the very modest position it had long occupied—since followed, it must be confessed, by a fall to the old position—was purely an outcome of the war. Nevertheless, in that brief period much useful work on the process was accomplished in this country, and since the war the attention of chemists and technologists has been attracted by the possibilities of extension and development of wood-distillation, more particularly in those parts of the Empire where, unlike Great Britain, raw material is plentiful and cheap. Mr. Bunbury has rendered considerable service, therefore, in producing for the use of English readers a volume in which the process of wood-distillation receives very comprehensive treatment both in its theoretical and practical aspects.

After a brief historical introduction and a description of the varieties of wood employed in the process, the author deals at some length with the physical properties and the chemistry of wood, including an account of the most recent views on the constitution of the cellulose and lignin molecules. Considerable space is devoted to the thermal decomposition of wood, the reactions which it involves, and the yields of commercial products which result. This section, occupying nearly one-half of the book, is largely composed of matter that is likely to appeal more strongly to the chemist than to the manufacturer. It includes, however, certain information of practical importance, more especially a summary of the recent work of Palmer and others on the influence of temperature and of moisture-content on the course of the process and the yields of products.

On the subject of yields the author has collected a large mass of data—chiefly the results of small-scale investigations—for American, European, Australian as well as Indian species of wood, and, in addition, for certain waste materials such as coconut shells, myrobalam kernels and gold mohur husks. Unfortunately, this chapter, dealing with one of the most important aspects of the process from the commercial point of view, is very confusing for the reader owing to the fact that the figures in the various tables are often based on different units. The author refers to the fallacy of using the cord, which may vary widely in weight, as a unit when comparing the yields from different species of wood; therefore, it might have been expected that, wherever possible, he would have recalculated the figures in the various tables to a common unit. For example, comparison between New South Wales woods and Indian woods is difficult, since the yields from the former are stated in gallons and cwts. per ton and the moisture-content is omitted, whereas, the figures for the latter represent percentages of the original weight of wood containing 15 per cent. of moisture. Further, the figures included in the three tables referring to the distillation of softwood are based on the cord, on 25 kilos, and on the ton, respectively. Apart from their bearing on the commercial prospects of the process, certain data in this chapter suggest that an interesting field of research is open to chemists who are prepared to investigate the reasons for the marked differences in yields from European and American hardwoods on the one hand, and tropical and sub-tropical hardwoods on the other.

The second half of the book deals with wood distillation on a commercial scale, and includes descriptions of the lay-out of a factory and the types of plant employed at the different stages of the process, as well as a detailed account of the various operations which the process involves. This section is well arranged; the introduction of flow-sheets showing the course of the process renders the subject-matter easy to follow, and the illustrations and drawings are usually well chosen and exceptionally clear. Practically every modern method of distilling wood and working up the distillate receives attention from the author, and it is probable that some of the information—for example, details of the construction and operation of the recently developed Swedish " blowing ovens " —is quite new to English and possibly American wood distillers. A chapter is also devoted to the distillation of wood-waste, and an interesting and excellently illustrated account is given of the various processes for the production of illuminating- and power-gas from wood, a subject of increasing importance in industry. In view of the labour which the author has expended on this portion of the book, it is unfortunate that, in many instances, he has omitted any criticism or advice in regard to the various types of plant and systems of operation described. In this connexion some consideration of relative costs and relative advantages and disadvantages would have added greatly to the value of the book. For example, it would be interesting to know whether the direct treatment of calcium acetate liquor in a continuous still for the removal of naphtha can really be regarded as sounder practice generally, than preliminary treatment in a lime-lees still and subsequent concentration of the naphtha in a continuous still. The author mentions the main difficulty attaching to the former process, viz., the tendency for tarry matter to deposit on the plates and the necessity for its removal periodically; hence, it is rather surprising that, in view of his acquaintance with this difficulty, he has selected a particularly unsuitable design of three-column still (Fig. 83) for purposes of illustration. In this still the only method of gaining access to the plates of the boiling column is to remove each section separately; and in the rectifying column the majority of the plates are rivetted to the walls and are quite inaccessible without removing the rivets.

The precise function of a tar-separator is not always made quite clear, and it is not possible to agree altogether with Mr. Bunbury that smoke-hoods over the discharge-ends of the retorts are a luxury—at any rate, if the top of the setting is used as an acetate drying floor.

The chapter dealing with the destructive distillation of wood waste does not, unfortunately, give us very much information as to the real position and prospects of this branch of the industry. Various forms of plant are described, of which certain, it is to be feared, have not progressed very far beyond the blueprint stage. How far these recent developments are likely to overcome the inherent difficulties of treating this class of raw material still remains to be demonstrated. A short description of the chain-and-scraper type of mechanical retort might have found a place in the book. Though by no means perfect, it does represent a form of mechanical plant which has received a thorough trial on a manufacturing scale, especially in Great Britain, and is capable in certain conditions of yielding reasonably successful results.

The chapter on analytical methods is scarcely worthy of the book. In some cases the method of analysis is only very briefly described, and in others several alternative methods are given, without any attempt to indicate their relative values; for example, four different methods of determining acetone in wood alcohol. A reproduction of the British Government specification for denaturing wood-naphtha, which is almost invariably the form of naphtha produced by the British wood-distiller, and some information concerning the examination of pure methyl alcohol intended for the manufacture of dyestuffs, etc., would have proved useful.

The book concludes with a series of statistical data, which indicate the magnitude of the industry in various countries.

This volume must be regarded as a distinct contribution to the literature on the subject of wood-distillation; but, in the event of a further edition becoming necessary, the author might perhaps consider the advisability of curtailing his treatment of the more theoretical aspects of the subject, and devoting greater attention to the problems of wood-distillation as a commercial undertaking. The book would then be likely to appeal more strongly to numerous individuals in various parts of the world, who, having large quantities of wood-waste at their disposal, are attracted by the possibilities of distillation and are anxious to know what it will involve in capital expenditure, operating costs, labour, etc., and particularly to be guided in the choice of plant suited to the conditions in which the process will be carried out.

Alex. Rule

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

There has been a slightly better demand during last week, but general improvement is not by any means decided. Both home trade and export business are more promising and prices all round are well maintained.

Acetic Acid, 40% tech.	£24 per ton. Still firm, but rather less inquiry.
Acid Hydrochloric	3s. 9d.-5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw.	£24 10s. per ton. Quiet.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Demand steady, export inquiry good.
Arsenic (White)	£71-£74 per ton. Somewhat easier.
Bleaching Powder	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Business much below normal.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand.
Copper Sulphate	£27 per ton.
Potash Caustic	£33-£34 per ton. Little moving.
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Potass. Chlorate	3d.-4d. per lb. Very dull.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76%	£20-£21 per ton. Steady demand.
Soda Crystals	£5 5s.-£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£26 per ton. Very scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	2¾d.-3¼d. per lb. Very dull.
Sod. Nitrate refd. 96%	£13 5s.-£13 10s. per ton ex Liverpool.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	£15-£16 per ton carr. paid. Very quiet.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£26-£28 per ton according to quantity.
Carbon Black	1s. 5½d. per lb. ex wharf. Still very scarce.
Chromium Oxide	1s. 5d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb. Firmer on advance in price of Rape Seed Oil.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood-distillation products.

Acetate of Lime—	
Brown	£10 15s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 10s. per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 9d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£6 per ton d/d.
Brown Sugar of Lead	£45 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 4½d.-1s. 5d. per lb. A better demand at these prices.
Crude 60's	3s. 4d.-3s. 6d. per gall. Not much business.
Acid Cresylic—97/99	2s. 0d.-2s. 5d. per gall. Demand fairly good.
Pale 95%	1s. 10d.-2s. 4d. per gall.
Dark	1s. 10d.-2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	9d.-11d. per gall. Not much demand.
Unstrained	8¼d.-9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1¼d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.
Pure	2s.-2s. 2d. per gall. No business.
Toluole—90%	1s. 9d.-2s. per gall. Quiet.
Pure	2s.-2s. 6d. per gall. Not much inquiry.
Xylol	3s.-4s. per gall. according to quality. Good demand.

Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil	8d.-9¾d. per gall. Market steady. Good demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.-10½d. per gall.
Solvent 90/160	1s. 6d.-1s. 9d. per gall. Market quiet.
Solvent 90/190	1s. 5d.-1s. 7½d. per gall. Market moderately active.
Naphthalene Crude—	
Drained Creosote Salts	£6-£8 per ton. Fair demand. Supply short.
Whizzed or hot pressed	£11-£14 per ton. Plenty of inquiries.
Naphthalene—	
Crystals	£18 per ton.
Flaked	£16 10s. per ton.
Pitch, medium soft	No business for this season. Prices for Autumn delivery 100s.-110s. per ton. f.a.s. Manchester.
Pyridine—90/140	13s. 6d.-16s. 9d. per gall. Dearer. Demand still good.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Since the beginning of June there has been a decided improvement in business in aniline dyestuffs. There is considerably more inquiry about and orders have improved both in number and weight. There is every likelihood of still further improvement in the near future.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 9d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works Good demand.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market has been quiet, and prices weaker in consequence of lack of business.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. 3d.-3s. 4d. per lb. Steady demand. Price well maintained.
Acid, Benzoic	2s.-2s. 9d. per lb. Still very scarce.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8¾d. per lb., less 5%.
Acid, Gallic	3s. per lb. Steady demand.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d.-2s. 3d. per lb. Weaker.
Acid, Tannic	3s. 3d. per lb.
Acid, Tartaric	1s. 4d. per lb. Demand improved. Also more demand from the Continent.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d. per lb. Slow of sale.
Amidopyrin	14s. per lb.
Ammon. Benzoate	3s. 3d.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. per oz.
Barbitone	20s. per lb., but difficult to find spot supplies at this figure.
Benzonaphthol	4s. 6d. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Potass. 8d., Sod. 9d., Ammon. 10d. per lb.. Slightly weaker in some holders' hands.
Calcium Lactate	2s. 9d. per lb. for best makes.
Chloral Hydrate	4s. per lb.
Chloroform	2s. 2d. per lb. for cwt. lots.
Creosote Carbonate	9s. lb. Demand negligible.
Formaldehyde 40%	£90-£92 per ton. Very firm.
Guiacol Carbonate	8s. 6d. per lb.
Hexamine	4s. per lb. down to 3s. 10d. for ½ ton lots.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Market good with considerable inquiry.
Magnesium Carbonate—	
Light Commercial	£37-£38 per ton net, according to quantity.

Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	1s. 9d.-2s. per lb. Good demand.
Menthol	35s. per lb. spot.
Methyl Salicylate	2s. 6d. per lb. for carboys. In slightly better demand.
Methyl Sulphonal	15s. per lb.
Mercurials	Market weaker.
Paraformaldehyde	3s. 6d. per lb. Weak.
Paraldehyde	1s. 6d. per lb. accepted for large orders.
Phenacetin	6s. 6d. per lb. spot value. Very steady.
Phenazone	7s. 6d. per lb. Very firm.
Phenolphthalein	6s. 6d. per lb. now wanted by most holders. Considerable advance in view of shortage.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	96s.-98s. per cwt., less 2½%.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. Demand still continues good.
Potass. Permanganate	10d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	6s. per lb. still quoted.
Salol	2s. 9d. per lb.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 9d. per lb. now wanted by holders. Still in short supply, fresh stocks being quickly absorbed.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality.
Sod. Hyposulphite—	
Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	80s.-82s. per cwt. net.
Sod. Salicylate	Demand not so good. Powder is slightly weaker at 2s. 8d. per lb., with crystal at 2s. 10d. per lb.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. per ton, according to quantity for home trade, 1-cwt. packages included.
Sulphonal	15s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.
Thymol	17s. per lb. for genuine white.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	4s. 3d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	2s. 9d. per lb.
Benzyl Benzoate	3s. 3d. ,, ,,
Cinnamic Aldehyde	14s. 9d. ,, ,,
Coumarin	18s. 6d. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	15s. ,, ,,
Ethyl Phthalate	4s. 3d. ,, ,,
Eugenol	11s. 6d. ,, ,,
Geraniol (Palmarosa)	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	16s. 6d. per lb.
Linalol ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	25s. 6d. ,, ,,
Methyl Anthranilate	6s. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Xylol	10s. 6d. ,, ,, Dearor.
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Safrol	2s. 3d. ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	23s.-24s. per lb. Market well maintained. Demand is brisker.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	2s. ,, ,,
Bergamot Oil	12s. 6d. ,, ,, spot.
Bourbon Geranium Oil	31s. 6d. ,, ,,
Cananga Oil, Java	9s. ,, ,,
Cinnamon Oil, Leaf	4½d. per oz.
Cassia Oil 80/85%	10s. 9d. per lb. Sharp advance.
Citronella Oil—	
Java 85/90%	4s. 2d. ,, ,,
Ceylon	3s. 7d. ,, ,, Dearer.
Clove Oil	8s.-8s. 6d. per lb.
Eucalyptus Oil 70/75%	1s. 10d. per lb. Dearer.
Lavender Oil, Mont Blanc 38/40%	13s. ,, ,,
Lemon Oil	3s. 1d. ,, ,,
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	13s. per lb. Advanced.
Otto of Rose Oil—	
Anatolian	24s. per oz.
Bulgarian	30s. per oz.
Palma Rosa Oil	17s. 6d. per lb.
Peppermint Oil—	
English	80s. ,, ,,
Wayne County	13s. ,, ,,
Japanese	6s. 7½d. ,, ,, Advanced.
Petitgrain Oil	7s. 6d. ,, ,, Lower.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JUNE 22, 1923 No. 25

EDITORIAL

CHEMISTRY, both Pure and Applied, is receiving considerable attention this week in Cambridge. The Union Internationale, notwithstanding its title, is mainly concerned with Pure Chemistry; all the discussions held under its auspices this week related to theoretical chemistry and were interesting chiefly to those whose knowledge of the science is both general and profound. The Society of Chemical Industry's meeting begins as we go to press and seems likely to be a very successful one. Cambridge is an ideal place for such congresses. The foreign delegates are much interested in the college life and, as many of them are living in the colleges and lunching and dining in the ancient halls, they have a very good opportunity of acquiring something of the spirit of the place and a knowledge of the circumstances in which our young men receive their University education. So far as the International Union is concerned, this is the largest gathering ever held, and there are many more ladies than have hitherto attended one of its meetings; the social side of the meeting has been very pleasant in spite of cold and cheerless weather. On Tuesday night the banquet in the great hall of Trinity was a magnificent occasion; the antique solemnity of the building, the rich colours of the academic robes and the ladies' dresses, the excellence and brevity of the speeches and the considerable number of distinguished people, made a wonderful impression. The Vice-Chancellor and the heads of half-a-dozen colleges were there, Cambridge physics was represented by Sir J. J. Thomson, Sir Ernest Rutherford and Dr. Aston, though the latter does indeed stand on the very border of the blest promised land; chemistry was represented very worthily, and among the foreign names which occur are such widely known ones as Professors Haller, Moureu, and Lindet from France, Paterno and Nasini from Italy, Bancroft and Lewis from the States, Cohen and Kruyt from Holland, Swartz from Belgium, Pictet from Switzerland and among the many distinguished men outside the academic circles may be mentioned Prince Ginori Conti, Monsieur Kestner, and so on. The British delegation was a strong one and, on the whole, fully representative of all branches of the science, but it was a pity that the President of the Chemical Society was unable to be present.

* * *

So far as can be judged by this meeting, the most valuable part of these congresses is the opportunity afforded of talking over chemical topics with chemists from other countries; not merely making the acquaintance of a man whose work has perhaps long been familiar, but the discussion of this with him and the presentation of the subject from a new point of view. The four formal discussions were interesting and probably of value to those who, with incessant care, devote themselves to such hobbies as oxidation and tautomerism. On the other hand, a good deal of the committee work appears to us to be not worth the time and expense involved. Three or four hours of rather casual talk by a body of men selected in a somewhat fortuitous manner, on such subjects as industrial hygiene, solid combustibles, or international patents, leads nowhere, and the subsequent expenditure of about the same amount of time in drawing up and revising a report to be formally presented and adopted, too often leads only to a suggestion that the committee continues its labours for another year. The committee on the elements does valuable work, but then the members of it are selected with some care, not chosen because they happen to be at Brussels or Lyons at a particular time. The committee on the elements, moreover, carries on its work by correspondence in the intervals of its meetings. If this committee continues its activities, and perhaps two other committees were formed on similar lines, and the rest of the committees allowed to die a painless death, we are of opinion the usefulness of the Union would be increased and the pleasure of its meetings not diminished.

A different set of circumstances affects the Annual Meeting of the Society of Chemical Industry. This Society does not have a chrysalis state which terminates each summer and changes into a short and intensely active life for which the previous months are merely a preparation. The Society of Chemical Industry during the autumn, winter and spring is hard at work collecting and disseminating information of value to those who are concerned in applied chemistry. Its meeting in the summer has, at least this year, a twofold character, and its importance must be considered both from the point of view of the public and of its own members. From the external or public point of view it affords an opportunity of making widely known to all classes of the community the importance of chemistry to the manufactures and commerce of the country, its powerful influence in promoting the arts which form so large a part of our modern civilisation and the supreme necessity of maintaining our science in a state of efficiency second to none in the world. Incidentally, it should be a means of enabling the Society to show how much its members have contributed towards these very objects and how the public may feel confident that their interests, so far as applied chemistry is concerned, are in safe hands. As to the internal or social side, the annual meeting is of the greatest value in enabling us all to know each other better. It was suggested to a committee of divines who began their report, "Conscious as we are of our infirmities," that this might be altered so as to read, "Conscious as we are of each other's infirmities." At such meetings we find out that the other man's infirmities, when we come to know him, are less than we imagined, and that the brusque remarks we read in his contributions are accompanied by a smile or a twinkle of the eye which deprives them of all offence. The weighty observations of Dr. Armstrong in his Presidential Address on the relationship between science and industry and on the relation between this Society and the public will be widely read and deserve the closest attention. We have few spokesmen who appeal to the public; we have few Fellows of the Royal Society who can speak to plain business men; we have few chemists who not only attain to distinction in their own subject, but are willing to devote their spare time to that public work of organisation which is so necessary. Dr. Armstrong is all these, and we are confident that the remarks he has made with so much authority will not only receive the attention they deserve, but will also stimulate a large number of chemists to put their shoulders to the wheel and help to make notable progress.

* * *

It was significant that, at the first corporate meeting of the Institution of Chemical Engineers, a discussion should have been held on the question of the training of the chemical engineer. Hardly any question is more fruitful of thorny discussion than that of education; it is at least as old as the human race, and one may presume that even primitive man argued long over the best methods of training the makers of stone axes, possibly resorting to methods of demonstration forbidden in these more peaceful days. We read the account of the discussion on the training of the chemical engineer with great interest, and were not surprised to find that a system of education advocated, on the grounds of its success, by one speaker, was rejected by another, who adduced equally good evidence for its failure. The question is so very difficult, be it that of educating the chemist, the chemical engineer, or even a skilled worker. Deductions from a survey of methods of education practised in other countries might possibly be rejected on the grounds that the conditions under which they are applied are different from those obtaining here. But this at least shows how elastic must be any system of education which is finally adopted, for a chemist or chemical engineer properly so called ought, we should imagine, to be equally competent, no matter what school he has passed through. One great difference between this and Continental countries is that abroad there is a more ready spirit of co-operation. Here we are well aware of the spirit of team-work, but its application outside the realm of sport is still not too frequent, and so it was with considerable interest that we read an account of an "instructional excursion" of the Royal Higher School of Industrial Chemistry at Bologna. The students, accompanied by the director of the school and three of the lecturers, spent the Easter vacation visiting industrial and mining centres in Tuscany. Visits were paid to a peat works, factories producing glass, copper, and cement, and the borax works at Larderello, where the party stopped one night as the guests of the Società Boracifera. The account concludes with the statement that the excursion was highly successful. Of its educational value there can be little doubt, and this led us to wonder whether such excursions would ever become a custom of our chemical schools. Of course, visits to works have long been customary adjuncts of scientific meetings, but for students? On questioning a manufacturer he replied that he did not believe such excursions were of great value, and thought that manufacturers would not encourage them. Apparently, they think otherwise on the Continent. However, the Institution of Chemical Engineers is to be congratulated on the way it faced a most difficult and important problem at its first corporate meeting, and we shall await with more than usual interest the publication of the curriculum for the training of the chemical engineer which, we understand, the Institution hopes to prepare during the coming year.

CHEMISTRY AND INDUSTRY

Address by the President

Dr. E. F. ARMSTRONG, F.R.S.

At the Annual General Meeting, Cambridge, 1923

This year's meeting marks a departure from the traditions of our Society. Instead of meeting in an industrial centre, we find ourselves for the first time amidst the colleges of one of the ancient seats of learning, "Where graced with many a classic spoil Cam rolls his reverend stream along."

Obviously, an address delivered under the influence of academic surroundings must take cognisance of the influence of science on industry. Such a subject were indeed far too wide for me, but happily it can be limited to chemical science. Holding, as we must, that industry in its turn has its reflex effect on science, it will be profitable to survey our subject from both aspects.

Science to-day—and chemical science offers no exception—is as it is owing to the patient labours of its disciples who have devised theories and put them to the test, only to discard them for other hypotheses which in their turn have been abandoned as always the knowledge of fact, based on experiment, increased. From time to time brilliant men have arisen more gifted than their contemporaries, either as experimenters or theorists, who have brought about progress, but it is correct to say that science is conservative and that its teachings are to a large extent based on tradition. There are, indeed, many dreamers amongst its votaries, but their dreams will first be regarded as heresies if they fail to conform to the orthodox. As Faraday said: "We receive as friendly that which agrees with, we resist with dislike that which opposes us; whereas the very reverse is required by every dictate of common sense."

Industry, too, has its traditions based on the ancient practice of rule of thumb; but, in the main, stern necessity based on the application of the principle of the survival of the fittest, has produced the methods of trial and error which in the hands of the venturesome have led to many discoveries to the great benefit of mankind. Such pioneer work to-day in all well-ordered industries is followed up by proper scientific investigation to understand the why and the wherefore, the answers to these questions in their turn leading invariably to improvements in the original process.

Industry cannot afford to neglect chemical science and its teachings. Just as in the domain of sociology those who disregard the past are not likely to cherish any real visions for the future, so in industry neglect, that is, disregard of science, will inevitably lead to failure to progress. There can be no question that the future of industry largely depends on the application of scientific principles to production, and that chemists should be exceptionally competent to advise on such matters.

Men of science necessarily proceed, step by step, along the pathway of known facts in searching for their conclusions, seeking knowledge may be for the sake of knowledge—which I hold not in itself to be a thing ignoble—may be for the sake of wisdom, seldom for the sake of gain. The inventor, like the dreamer, is impatient of him who would always verify his route and often seeks to reach the goal at the risk of being accused of vagueness by the scientist who seeks to follow him.

In any technical business—and all manufactures are highly technical nowadays—so long as all goes well the chemist is scarcely required, production being a question of organisation and management. But things never do go well for a long period of time; difficulties are always arising, and it is then that the co-operation of the technical expert—of the scientifically trained man, the chemist—is required.

The progressive manufacturer to-day—and there should be no others—realises this point: it remains for the chemist to fit himself by his training and experience to give the assistance required. If he fail, then science is blamed: some of us in industry to-day feel justified in asking: "Are there not too many failures?"

In the first place, no one should enter the chemical profession unless he feels a definite call to do so; chemistry is far too exacting a mistress. Secondly, the life of the chemist is one of investigation; he must always be asking questions as to the why and the wherefore, and must therefore possess in the highest degree the spirit of initiative, of research. His training must have been primarily in the methods of research, of original investigation; in no other way is it possible to cultivate those faculties which he will daily be called upon to exercise. Our chemical schools must be pervaded by an atmosphere of research; the proper spirit of inquisitiveness must be awakened and maintained in them until it becomes a habit. Such an atmosphere is effective above all else in bringing out individuality and self-reliance by fostering enthusiasm for one's work. If our colleges fail to provide the right type of men, then the manufacturer will have just cause for complaint. It is the exceptional man who is worth training; it is he who moves the world.

There has passed from amongst us this year perhaps the most brilliant experimentalist of his, or any, time, our President in 1887–8, Sir James Dewar. He was active in the laboratory until the end came in his eighty-first year, and the last of his renowned discourses at the Royal Institution showed no indication of any ageing of his mental activity. Dewar could only be appreciated at his very best—at all events in later years—by those who knew him. He was an artist in himself, a connoisseur with a love for the good, the beautiful, the uncommon, the interesting, and, above all, the genuine. As my father wrote me on the news of his death: "How much our atmosphere has lost its charm and colour will only gradually be noticed."

Full accounts of his life and work will appear in other places, but we can to-day in honouring his memory learn much from the manner of his success. Dewar's incursions into industry were many, probably all of them fruitful; if we had had more Dewars our chemical industry would, to-day, stand on a different footing.

It being granted that the right type of man is available—and I would here urge that the more we can attract the highest social classes into our ranks the better—and that the early training and spirit at our colleges are satisfactory it remains to enquire as to the facilities for the final post-graduate training which is all essential to the chemist who hopes to take a high place in industry. Our laboratories have, during the past few years, been greatly overcrowded and the staffs overworked, but many extensions are in progress and the pressure of students is likely to lessen in the near future: there is a widely-reported shortage of equipment and of funds for laboratory work which should be noted by manufacturers and others able to make donations to the cause of science. For post-graduates numerous scholarships and fellowships are now available and the research funds of the Chemical Society and other societies provide assistance in the purchase of equipment and materials; the pages of our journals give ample testimony to the increased quantity of original work being done in this country.

It must be remembered that at the time of the foundation of our Society in 1881 the facilities for obtaining a training in chemistry and physics were very limited and it was very difficult for a young man desirous of receiving an extended training to obtain financial aid.

During the next twenty years excellent facilities were created on all sides, and I may mention in particular the Finsbury Technical College, the Central Technical College, and later the London university colleges and the provincial universities. The existence of scholarships enabled many students to enjoy a training at these institutions which would otherwise have been denied to them, but at the end of their college and university courses only a very limited few are able to take advantage of that further course of training, often at a foreign university, which is required to fit a chemist to undertake research work and to qualify him for the higher posts in industry. It will be generally agreed that no scheme of endowment has borne more generous fruit than that of the 1851 Exhibition Travelling Fellowships; various institutions were allowed to nominate a Fellow for a year, the grant being renewed on the report of competent referees. Many of the best known men in chemical circles to-day were holders of these Fellowships.

Professors in the closing years of the nineteenth century frequently emphasised the need of research fellowships to enable an increasing number of graduates to stay on for the fourth, fifth and sixth years at college for training as research workers. Many such fellowships were founded by the generosity of the city livery companies during the nineties, notably the Salters' Company and the Leathersellers' Company; many of these Fellows entered industry and their record, although it is barely twenty-five years since the first of them left college, is already a very satisfactory one. The memorial to our former President, Sir William Ramsay, has also, in part, taken the form of the endowment of research fellowships, and the more recent scheme devised by the Salters' Company and known as the Salters' Institute is also based on a system of research Fellows. Before dealing with this in the detail which it deserves, mention must also be made of the numerous grants to individual research workers which are made by the Department of Industrial and Scientific Research.

On the creation of the Department in 1915, it was empowered to initiate proposals for the establishment and award of research studentships and fellowships, and a scheme has come into being which is described in the official publication of the Department.*

* Notes on Grants to Research Workers and Students.—H.M. Stationery Office, 1922.

As illustrating the magnitude of the scheme I may state that in 1921-22, 280 awards were made out of about double this number of applications, the grants being allocated as follows :—

Students in training	205
Research workers	55
Laboratory assistants	14
Equipment	6

No less than 163 of the recipients were workers in the subject of chemistry.

The Salters' Institute of Industrial Chemistry was founded by the Salters' Company with the idea of fostering and benefiting industrial chemistry by training suitable chemists who would eventually be able to occupy the higher posts in industry. The average chemist who leaves a University laboratory with an honours degree is not immediately at home in industry, and consequently during the process of his development he is often pushed into a backwater. The idea of the Salters' Institute is to select from the Universities men with pass degrees, and award to them Salters' Fellowships for a period of years, so enabling them to undertake a special training under the guidance of the Director of the Institute, so as to equip them for a high position in whatever branch of chemical industry they might propose to take up. It was felt by the Livery Company that a great benefit would be conferred on chemical industry by providing in this way for the training of a limited number of really first-class men on really practical lines.

The necessarily brief outline given shows that the position of the country in this respect is a good one, and that to-day we are far from lacking facilities for training the research worker and affording financial aid during the period of training. Indeed, the thought arises whether entry to the profession is not being made too easy at this stage, though it may be urged that this creates the element of competition which alone can stimulate imperfect man to his best efforts.

As regards those entering industry, I think many of my colleagues will agree with me that the time is ripe for a Conference with the teachers and a broad exchange of views either in public or in private where frank speaking can be the order of the day. I think I am justified in saying that we manufacturers find it very difficult to get the type of man we require. Possibly our Society can organise such a Conference, and I have in mind the utility of a somewhat similar meeting with Professor Meldola in the Chair, held under the auspices of the Institute. My remarks must not be held to place the blame on the teachers ; perhaps the material they have to work on is unsuitable.

Research in industry, above all in the chemical industry, is no new thing ; it is perhaps a little older than the industry itself, as the man who started the latter was certainly an original investigator.

Progressive firms have always had research departments, even though they have not publicly advertised the fact to the same extent as the German dye industry. Much, however, of the work has been more in the nature of the investigation of factory processes, mishaps and troubles, or the seeking of new applications for the firms' products and by-products. Only a limited number of companies have installed separate research departments with a large and independent staff working on a definite plan over a period of years. Naturally it is only the largest corporations that can undertake such a responsibility, and it is or was our national characteristic to prefer to manufacture in smaller units than those of the large corporations on the continents of Europe and America. Furthermore, until recently there was no surplus of skilled research workers.

As a result of the lessons learnt during the war, all this is now to be changed : scientific and industrial research in this country has during the last few years received direct and very definite State encouragement under the auspices of a Committee of the Privy Council, a new Department of Scientific and Industrial Research having been created for the purpose with Sir William McCormick as Chairman and Sir Frank Heath as Secretary. Perhaps the most interesting venture of this department has been the setting up of what are known as Industrial Research Associations, of which twenty-two are in active operation, and two others have received licences from the Board of Trade. Anyone conversant with the difficulties which confront research in industry will agree that some little time must elapse before results of real practical value are produced, and only a few of the Associations have been in existence long enough to have issued reports giving justification for their existence : actually two of the Research Associations have just passed into their fifth year of grant aid, while four others have commenced their fourth year. It will be remembered that when the scheme was started, it was thought that a period of five years would give a reasonable time for an industry to test the value of co-operative research, and it will be agreed that if the really fundamental problems of an industry are to be tackled, five years is no lavish space in which to found an institution, equip it with men and material, and produce results.

Broadly speaking, such research institutions are not intended for the largest firms able to organise and finance research laboratories of their own, but should be most useful to a combination of smaller firms, who in the past have not only been unable to incur the expenditure of a research department but have even been unwilling to contribute sums equivalent to no more than the yearly wage of an additional workman or foreman for the purpose of scientific investigation. Whether or no immediate results prove of practical value to the individual firms, it should become a point of honour with them to maintain a research institute within their industry.

The general scheme of these research institutions is too well known to need explanation here. It was considered that during the first five years of their existence, in which they received a monetary grant from the Department equal to the funds raised by their industry, sufficient would have been achieved to make the members of the research association willing to carry on the research, and even to increase their subscriptions, on finding that in the sixth year of their existence one-half of their previous income would cease. It may be noted that in the year 1921–22 the sum of £86,355 was paid in grants to the research associations.

The meaning of the word " research," particularly in its application to industry, is so often misunderstood that it is desirable to dwell a little on this subject. Pure research, as carried out by the investigator in the University or private laboratory, is in the main directed to affording proof or disproof, as the case may be, of existing theories, the research leading in practice to the detailed study of certain very limited problems ; the impulse for the particular piece of work being given by the bias of the individual and the work pursued for the pleasure it gives to the worker. Only those who have wrestled with Nature for her secrets can realise the joy of so doing.

The object of industry is definitely financial ; the object of industrial research is to work out new processes or improve existing onces. Investigations which have for their object the solution of special difficulties of particular processes and the utilisation of waste materials are not researches in the true sense of the word, although the solution of such problems would be to the financial advantage of the industry. These are matters more for the particular firm than for a research association.

In these research associations each industry should endeavour to develop on a scientific basis the fundamentals. Thus, it will be agreed that it is appropriate for the Portland Cement Research Association to endeavour to ascertain the exact nature of the compounds constituting Portland cement or to determine the ideal form of rotary kiln, and for the Cotton Research Association to study the fundamental properties of single cotton hairs rather than to undertake the investigation of the specific problems of a group of mills. Such fundamental problems are outside of the ordinary scheme of work of the research departments even of the largest firms engaged in the industry, whose chemists and physicists must always be more occupied with the immediate problems of the moment ; though work of this nature will be appropriately carried on as a side issue when time and resources permit and will in general be rewarded by brilliant practical and financial success, as witnessed by the achievements of the laboratories of the Eastman Kodak Company and the General Electric Company in America, and by Brunner, Mond and Co., and many others in our country.

Naturally, the scheme of the Department for Scientific and Industrial Research has not escaped criticism, but it seems to me that, from the point of view of our Society, we should suspend judgment until all the associations have had at least five years' experience, realising that the development of scientific research in twenty-four of our leading industries, and the interest taken by the manufacturers themselves in this work, cannot fail to be of far-reaching importance to our future as a manufacturing nation. The scientific workers on the staff of the research associations must justify by their diligence the confidence which their employers and we, their colleagues, have placed in them.

Any assemblage of men of science willing to face the facts will agree that science, scientific method, and scientific research have not yet won that position within the realm and its industries that is requisite if we are to maintain our place among the nations. It is customary to attribute the blame for this to the other party and speak of the " Neglect of Science." Perhaps it is desirable to have occasionally what our American cousins are fond of calling a heart to heart talk to ascertain whether all is well in our own camp.

During my year of office, in talking to the younger men in the sections, I have never failed to emphasise the fact that whilst they gain their first appointments on their qualifications as chemists they succeed afterwards because of their ability as men. Knowledge may be power but not until it is applied to the service of humanity. " Truth latent in the mind is wisdom that is hid and treasure that is not seen " (Richard de Bury). Probably the keynote to success in this and the next generation lies in all that is connoted by the term " service." It will not be enough to make and to offer for sale, caring not for the ultimate fate of the article ; rather must the manufacturer take an active part in instructing and advising the buyer. It was the early realisation of this fact, perhaps even more than any reputed technical superiority or cheapness of product, which formerly enabled the German dye industry to obtain its hold on the markets of the world.

Chemists must also be prepared to give service, above all they must be practical. It cannot be said too emphatically that the young chemist on leaving his university must have had such training as enables him to be at least a chemist: in the first place, a competent analyst—for analysis is the very basis of our science—and, secondly, a competent manipulator in the laboratory, with real experience in handling organic substances. He seldom gets an opportunity later in life to acquire this knowledge, whereas specialisation, which is mainly a question of application, comes all too early to most of us.

It is an admitted fact in industry to-day that far too many of the present graduates from the universities are weak on the purely chemical side; it is this experience that has caused me to urge that the prime duty of the university course should be to produce chemists and not "labelled chemists." From this point of view we as a profession should be proud to call ourselves "chemists" and not add an apologetic descriptive prefix. It is the application of chemistry in agriculture and in engineering that is wanted, not agricultural chemists, and I have even had the temerity to quarrel with the term "chemical engineer," believing that there is no such person, though at the same time positive that the highest gift his fairy godmother can give to the chemist is a knowledge of and still more an inclination for engineering—an art, not a science.

It may be as well to add that I regard physics as a branch of chemistry; a thorough knowledge of physics and physical chemistry is part and parcel of the chemist's training from his first week at college—though I cannot see why applied physical chemistry should be called "chemical engineering."

Chemists as a class are apt further to overlook that whilst their science is the most practical of all, being applied to every detail of everyday life, yet it has a jargon even more difficult to the layman than that used in the biological sciences. It is within our powers to alter this reproach, and whilst for our transactions it is convenient and proper to use the precise and wholly satisfactory terminology which is expressive of our knowledge, we must strive to approach the public using a plain honest language which they can understand. Frankly, it is from this point of view that I personally attach so much importance to the efforts we are making in the issue of our weekly *Journal*, and though its form may evoke criticism from those of an older school, the appreciation it has received from the very point of view I have in mind has more than justified our somewhat arduous labours. Our new venture must work out its own salvation, remembering always that we live in the present, that we have to build for the future, though we can learn and profit by our experience in the past.

It is possible to meet people of intelligence ready to discuss practically any subject of everyday importance, except chemistry. They have at best but a vague idea of the analyst and have no conception of constructive and creative chemistry.

The war gave chemists a chance we have never had before to bring our capabilities and achievements before the nation, and for a while we strutted in the limelight, both as destroyers and conservers of human life. But we were unprepared as a body, disloyal to the extent that we are not sufficiently proud of our profession and unable to take advantage of the opportunity—hardly any one of us was able and willing "to preach the gospel" as an American colleague puts it "of the value and importance of chemistry to the past, present, and future progress of mankind and to preach it in terms which are acceptable and comprehensible to the layman." We have not established any central organisation among our chemical societies responsible for this type of propaganda. Chemistry, if not more remote, is less obvious to the layman in its effects, though it obtrudes just as much on his daily life as medicine or engineering.

The engineer can bridge the river, annihilate distance by the train and steamer, harness the tides or, if of the electrical fraternity, turn the waterfall into light and power. Chemists must lay more stress on the fact that they beautify the world, or, at least, the feminine part of it, with their dyestuffs, turn wood into silk stockings, make our water potable, and render a thousand other like services to the community. Once we and the public realise that the professions of chemist and engineer are mutually complementary, then we have gone a long way towards attaining as a profession that place in the sun which rightly belongs to us. It is an interesting fact that during the month of April the New York Section of the American Chemical Society arranged for five popular talks on chemical topics to be broadcasted to people described as radio fans. This is regarded as an important test of the popularisation of chemistry. It is to be hoped our London Section will make efforts to follow suit.

This year is memorable in that we celebrate the Centenary of the establishment of the alkali industry in this country. The Leblanc process was not adopted in England, except on a very limited scale, until 1823, owing very largely to the existence of a duty of £30 per ton on common salt, which was repealed that year. Mr. James Muspratt then erected his works in Liverpool.

In a little work on British Chemical Manufactures, by George Dodd, published in 1844, occurs the statement that chemical works are affected both by political and by scientific events in a remarkable degree. "It is reasonable that they should be affected by the current of scientific discovery, but the bearing of political matters may not be so obvious. The imposition or the removal of an excise duty on a commodity of home production; the imposition or the removal of a customs' duty on an imported foreign product; the establishment or the cessation of commercial intercourse with a country richly provided with some commodity which we require in our manufactures ; the concentration, in the hands of a few, of a commodity required by the many ; the legislative enactments which occasionally give rise to a demand for a particular commodity at a particular time : all or any of these may work great changes in the arrangements of an establishment where chemical manufactures are carried on, irrespective of the still greater changes which naturally result from scientific discoveries in chemistry."

This quotation, though eighty years old, might have been extracted from the Chairman's Annual Address to the Association of British Chemical Manufacturers, and illustrates that then, as now, science and politics are the two main factors influencing the future of our chemical industries.

In the early 'forties, the cost of salt was 10s. to 12s. per ton, so that a duty of £30 per ton was fifty or sixty times as great as the cost of the article itself. Evidently the production of soda from salt was not to be thought of commercially. Soda was obtained from kelp, the ash remaining after the burning of the seaweed collected on the shores of the Scottish Highlands—an industry created about the middle of the eighteenth century. The weed was cut by the sickle at low water, conveyed to dry land on horseback, spread out to dry and burnt in coffers generally constructed in stone, or in the Orkneys merely excavated in the earth. The amount of labour required was considerable, and the consequent distress among the Highlanders when the industry was superseded very great. Soda was also obtained from barilla, imported from Spain and Italy in large quantities ; it was produced by burning a sea-plant called the *Salsola soda*, especially cultivated for the purpose.

The life history of Leblanc and his process is too well known to need reference here. At the time Muspratt started his works in the Vauxhall Road, Liverpool, Losh had already started a small works on the Tyne, and Tennant had made a beginning on the Clyde. Typical of the prejudice, which even to-day exists against the introduction of new articles, is the statement that when Muspratt commenced the production of soda ash he found the consumers of alkali so biased in favour of potash that he had actually to give the soda to the soap-boilers before they would use it, and even then he was condemned personally to superintend the making of the soap.

The new enterprise was soon successful, and in partnership with Gamble a new works was built at St. Helens. The alkali industry is essentially one which must be localised suitably for the supply of raw materials—*e.g.*, salt, limestone and coal, and for delivery of the finished product at home and abroad. Hence its main development in South Lancashire and Cheshire and on the Tyne and Clyde.

The subsequent rapid spread of the industry affords a fascinating chapter in the history of our industries. It was soon, however, attacked by troubles, and from 1832 to 1850 Muspratt was harassed by almost continuous and expensive litigation on account of the harm done by the escape of the hydrochloric acid vapours into the air. Finally, in 1850, he removed to Widnes and Flint, selecting sites for his works where less damage could be caused to the neighbouring countryside. The problem of absorbing the gases was finally overcome by William Gossage, of Widnes, perhaps the most inventive of all the practical chemists of the last century, who designed the absorption tower packed with coke, which is still generally in use, and conferred an incalculable benefit on the alkali trade. Curiously enough, Muspratt was incredulous with regard to this invention, and thought very large quantities of water would be necessary.

The partnership of Muspratt and Gamble only lasted two years, and in 1836 Joseph and James Crosfield, the soap-boilers of Warrington, became partners in Gamble's alkali business. Joseph Crosfield, alarmed at the damage done by the escaping acid fumes, insisted on the immediate adoption of Gossage's patent, but Gamble was opposed to this, and the quarrel which ensued resulted in the dissolution of the partnership in 1845.

The Leblanc process reigned supreme for many years, until a serious competitor came with the successful operation of the ammonia-soda process, patented by Solvay in Belgium, but established in this country by Brunner, Mond and Co.

As Dr. Conroy has said in the delightful little brochure issued in April last by the United Alkali Company, " Solvay pointed the road to success, but it may truly be said that the great extension of the scale of operations is due to the genius of Mond and the chemical and engineering work done in this country."

Our Society may claim to take a personal interest in the celebrations of the United Alkali Company and of Brunner, Mond and Co., because, as might have been expected, prominent representatives of both firms have occupied the Presidential Chair. Dr. E. K. Muspratt is fortunately still with us ; he was our fifth President in 1885–86, following Sir Wm. Perkin, and is now our senior Past-President. Dr. Ludwig Mond held office in 1888–89 ; Eustace Carey in 1906–07.

The firm of Brunner, Mond and Co. commenced operations in 1873, and celebrates its Jubilee this month, when doubtless opportunity will be taken to publish a detailed contribution to the history of the enterprise. It may suffice here to say that Mr. J. T. Brunner and Dr. Ludwig Mond became friends when both were engaged at the Hutchinson Works at Widnes, a friendship which lasted until the death of Dr. Mond in December, 1909. Mond visited Belgium to make an agreement with Ernest Solvay as to manufacture in England, and on his return he and Brunner set up in partnership, selecting a site on the banks of the Weaver, which is to-day the famous Winnington Works. Those who know the history of the early days can best testify to the courage and tenacity and, indeed, moral qualities of every kind required to make the new process, first a technical, and ultimately a commercial success.

But fascinating as is the early history of the alkali trade, we are here concerned more with the causes of its success. At the end of its first century it stands perhaps in a stronger position than ever before; it is for us—especially for the younger men and for a generation yet unborn—to see that a hundred years hence the same may be said. The names of the great pioneers are known to us all and the outstanding qualities which led to their success. Such men we shall have again, though it take a later generation to appreciate their fame. Nothing could have been accomplished without "team" work, the united efforts of chemists, engineers, and labour alike supplemented by the efforts of the commercial side. This factor becomes of increasing importance as the size of the individual firms increases, and will continue to do so. Constant research and invention have been the arteries whereby fresh life-blood has been continually pumped into the industry; without these it would long ago have been extinct, and fresh research and invention, even out of proportion to the growth in magnitude of the industry, must be applied if its position is to be maintained in face of the competition of the world.

It is no doubt permissible for me to dwell a little on some very early history of the trade with which I am now connected, and I am fortunate in possessing two very early pamphlets entitled "A Short and True Relation concerning the Soap Business containing the several patents, proclamations—orders whereby the Soapemakers of London and others, His Majesty's Subjects, were damnified by the gentlemen that were the Patentees for Soape at Westminster, with the particular proceedings concerning the same," printed for Nicholas Bourne at the South Entrance of the Royal Exchange in 1641, and "A Looking glass for Sope Patentees or a Prospective Glasse making discovery of a new Project contrived and propounded (by the Sope Projectors) to the Parliament to monopolize the Soping mystery under pretence of good to the State in the duty of excise" printed in London in the year 1646.

The first pamphlet contains an account of a patent granted in 1622 to a Company for the exclusive manufacture of soap, under the title of the "Governor, Assistants and Fellows of the Society of Soapmakers of Westminster," on condition of their paying to His Majesty £4 per ton on 5000 tons annually. The manufacturers of that day (twenty in number) refused to join and acknowledge this Company; whereupon the Company obtained a proclamation forbidding, amongst other things, the sale of soap which had not been assayed by the Company. An information was then exhibited in the Star Chamber, in 1633, against sixteen London makers for opposing and affronting the letters patent, to which the defendants pleaded and demurred, etc., and after much discussion (all the defendants having been committed to prison for having put in their answer one day too late) the judges certified "all the answer except the first four words and last ten as fit to be expunged." And it was decreed that the defendants be imprisoned during His Majesty's pleasure, and fined in various sums from £1500 to £500. All were sent to prison. Fourteen remained there for forty weeks, and two died in prison. These tyrannical acts were followed by various proclamations and orders in council restricting the manufacture of soap except by the patentees, and fixing the price at which soap should be sold, and the materials from which it should be made. In 1635 many other soapmakers were committed to prison, and greater power was given by proclamation to the patentees upon their covenanting to pay £6 per ton on 5000 tons annually. In a short time, however, the patentees, having "vexed the whole kingdom with their soap for three years," obtained in the year 1637 a warrant from His Majesty for £40,000 in consideration of their giving up the patent, and £3000 for their houses, and obliged the soapmakers of London to pay them £20,000 for their materials, so that they might have use of their trade again, of which they had been deprived.

The second pamphlet, which contains copious quotations from the Scriptures, is of a very amusing character. The grievance of the Sopeboylers apparently was "that there are divers persons of mean condition who in many bycorners do make and sell soap not having been apprentices to that Trade." They suggested that the excise tax on potashes should be doubled, that being the principal material without which soap cannot be made, and that they should be themselves empowered to collect this, thereby controlling the use of potashes. The pamphleteer makes a vigorous protest against the project, stating "that the Patentees are not sope-boylers in the right of serving apprenticeships thereunto but Salters and Leathersellers and concerning sope-boyling it is not a manufacture but an art or mystery which every Freeman that knows how to boyle may as lawfully as themselves use."

The excise on potashes would press hardly on all other Trades. The pamphlet ends with an injunction to the Senators "from whom as from a fountain we expect that justice shall run like water and judgment like a mighty flood" and with regard to the unfortunate Soap Patentees, quotes "Can the Ethiopian change his skin or the leopard his spots, then can ye also do good that are accustomed to do evil."

Little is known of the trade from this time to 1704, when Queen Anne imposed the first excise duty. Several pamphlets and statements, on half-sheets, are to be found in the British Museum, containing petitions to be relieved from taxes, etc., but there is no account of the quantity manufactured.

Perhaps at some future date it may be opportune to give the early history of some of the existing soap firms. That they had difficulties is shown by the following extract, taken from a full account of the process of soap manufacture published in 1844 :—

" Lastly, and perhaps to the manufacturers the least pleasant of all, there are rooms and offices fitted up for the Excise-officers, one or more of whom are in the factory day and night. It is a great blot upon the fiscal arrangements of this country, and one which seriously affects the manufacture of malt, of glass, of soap, and many other articles, that in order to collect the duties levied on these commodities, the officers of the Excise are empowered to control, as it were, every step of the processes, and to regulate the extent to which any improvement in the operations may be carried.

" It is not the amount of duty collected to which we here refer ; this is another subject : it is the mode of collection which is so objectionable, by imposing impolitic checks to the natural course of improvement in manufacturing processes. Considerable ameliorations have, however, within a recent period, been made in the mode of collecting the revenue, and the survey of the premises of soap-manufacturers."

Although soap is now freed from the attentions of the Excise officer, our fine chemical trade is not so fortunate, and we can imagine many of our colleagues reading this paragraph with the feeling that there has not been much change in the course of eighty years.

It is desirable in my opinion to make a definite pronouncement on the need of co-ordinating in some way or other our various chemical societies, even at the risk of repeating much of what I have said during my visits to the sections. I am, moreover, encouraged to do this to-day because, if we let this opportunity pass by without taking action, it may be a considerable time before circumstances are again so favourable.

We chemists are excellently catered for by a number of organisations, each of which may be stated to fulfil a definite purpose, with the consequence that a large number of us belong to at least four societies and the majority of us to more than one. The result is that, as the societies expand, there is a great deal of overlapping, the total subscriptions fall heavily on the individual, and there is unnecessary expenditure, particularly on publications and on administration. On the other hand, as several names appear on more than one of the councils of our societies, there is already some measure of community of thought in their policies.

An unfortunate result of the present state of things is that no one society can claim to speak for the chemists as a whole; indeed, it repeatedly happens that two voices are heard when one would suffice.

If we briefly enumerate our societies and their activities in the broadest sense, in no way intending to be critical, we have first the Chemical Society, whose main function is to facilitate research, publishing the results in its transactions and making reference to current work easy by its abstracts and annual reports. The Chemical Society is representative of chemical science. The Institute of Chemistry is essentially a qualifying body, keeping a register of professional chemists and striving to create and maintain a high professional standard and protect the professional interests of chemists. The Society of Chemical Industry counts among its members all kinds of chemists, and seeks both to encourage the spread of chemistry in industry, to proclaim its importance publicly, and to assist the individual chemist. Its transactions deal with the more practical aspect of chemistry, its abstracts and the Annual Reports are invaluable to the works chemist and consultant, and its new venture may have a far-reaching effect on the one hand in knitting us all more closely together, and on the other in making us understandable to the general public. Our Society was the first to have active Sections all over the country, and its peripatetic annual meetings have afforded an opportunity — not perhaps always used — of bringing the objects and aims of chemists before a wider public. The Institute has latterly established local sections, thereby helping to form opinion amongst men who hitherto felt that they were too far away from headquarters for this to be possible. To this extent it has begun to overlap the activities of our own Society, but the holding of joint meetings, particularly joint social functions, in many of the centres during the past year shows that the spirit of close cooperation for which I am about to plead is already in existence.

Next I would allude to the Chemical Industry Club, yet in its infancy, but destined to play a very leading part in the fusion of interests. In possession of small yet very comfortable premises, withal centrally situated, it is an example, as yet only in miniature, of what perhaps some of us desire most of all—a central chemical house, a club and a headquarters, housing all the societies and their joint central administration and forming the centre of organised propaganda on behalf of the chemist and the utility of chemistry for the service of the State.

Next we have certain smaller societies, representing special sections of chemistry, as typified by the Society of Public Analysts and the Biochemical Society, and further those societies interested in certain sections of industry and admitting to membership practical members of the industry as well as chemists—*e.g.*, the Society of Dyers and Colourists. The Faraday Society plays a special *rôle* in organising and publishing joint discussions of the most valuable character on subjects on the borderline between physics and chemistry. Mention must lastly be made of the British Association of Chemists, a body whose exact status has still to be defined, but which at the moment fills many of the functions—to my mind useful ones—of the extreme left wing of our corporation.

The attempt was made a few years ago to bring into being a body common to all the societies, and, accordingly, the Federal Council for Pure and Applied Chemistry was formed. Composed of delegates from a number of the societies, its functions are to initiate and co-ordinate effort and generally to advise in matters affecting all the societies—*i.e.*, chemists in general. Whilst a body so constituted can only act with diplomatic slowness, it has already much to its credit, in particular the initiation of the International gatherings, one of which has so felicitously preceded our own meeting. It has, moreover, served as a model to other countries and to other sciences.

The Federal Council includes among its members the Association of British Chemical Manufacturers, which, though primarily a trade protection association, has its constitution very widely drawn and is active in promoting the application of science in industry. We have in the Federal Council a nucleus or skeleton organisation to which can be entrusted the difficult task of forming one great chemical society and raising the necessary funds for our future home, the Chemical House.

I would suggest that the time has come to make the definite proposal that it should become the agreed policy of some, if not all, the above societies to take steps as appear expedient to bring about a gradual confederation. It would appear obligatory that I should submit a very crude draft outline of a scheme. Chemists and others interested in chemistry would become members in the first place of the Confederation, and in the second of a particular Society or Section. The government would be in the hands of a Grand Council chosen in part from the members and in part nominated by the sections; the actual work would be done by an executive elected from among the Grand Council. Tho administration would be in the hands of a general manager, assisted by sectional secretaries. A staff of editors would produce the publications. The existing societies under this scheme would be incorporated as a whole so as to retain in full the great asset of their "goodwill," but would have their activities more closely defined.

Each society would continue to devote itself to the particular branch of the subject with which it had been associated in the past, but all overlapping would be entirely eliminated. The Institute would continue to act as an examining body and maintain a register of Fellows and Associates, who alone would be entitled to use the professional qualifications, F.I.C. and A.I.C.; the remainder would be simply members using no professional distinction. The unnecessary custom of using the letters F.C.S., which have no meaning whatsoever as a qualification in the professional sense, would also disappear. The Institute would also watch over the important question of professional etiquette.

Weighty committees would be established to deal with the Government departments and with public propaganda.

It is not difficult to outline a fairly full and comprehensive scheme, but this is better done by a committee than by an individual. It will suffice, therefore, for me to make the proposal that the Councils of all the Societies proceed to examine the question next session and consider the propriety of asking the Federal Council to form a Committee to study forthwith the desirability and practicability of federating the Chemical Societies.

Difficult as it will prove to effect the welding together of the British Chemical Societies into one body, yet this is bound to come about if the pressure from the rank and file is strong enough; indeed, it can succeed in no other way.

A much more delicate question will then remain to be settled before the profession of chemistry can take rank with medicine or the law. Indeed, we have amongst ourselves to decide whether the word "chemist" is to have as wide a meaning as the term "engineer" or a restricted meaning like the term "solicitor" or "accountant." The engineer may be at the very peak of the profession or occupy any other grade down to the skilled fitter. By "solicitor" or "accountant" a qualified man is understood. At present we cannot even lay claim to a monopoly in the application of the term "chemist," though I do not despair of educating the public on this point, but the outstanding feature is that the chemist may or may not be fully qualified.

If we are ever to rank as a profession, then we must resolutely close our ranks to all but the qualified, possibly using the term "chemical assistant," for the large number in works who will be unable to qualify through no fault of their own. But it is essential that all who practise chemistry, either as consultants, analysts, teachers, or in any other public capacity, are qualified. The Institute of Chemistry, now that it has filled its ranks and is really representative of the profession, should devote all its influence and resources to attain this end.

The harm and the mischief which are being done to-day by unqualified and incompetent—the two words are generally though not necessarily synonymous—persons who style themselves "chemists" is very considerable, far greater than most of us realise.

There is one matter of great importance to us as a Society. We were, until recently, solely concerned with industrial chemistry and chemical engineering, but now we have arranged with the Chemical Society to publish in *Chemistry and Industry* articles and news concerning pure and physical chemistry. The step we took last winter in arranging this and publishing our journal weekly involved close consideration of the financial considerations involved and a large measure of responsibility. Personally, I do not grudge the expenditure of a good deal of time and thought which I devoted to this question. I am satisfied that the step was wise in the interests of the science and industry in which we are engaged. This is, however, only the first stage of a long and arduous task which lies before us, and I appeal to you all, both pure and applied chemists, young and old, rich and poor, to help the Federal Council for Pure and Applied Chemistry and this Society, which constitutes an important constituent of the Federal Council, in the effort now being made to do something to co-ordinate the activities of the various societies, associations, and the Club in a manner which will be helpful to chemistry and chemists. The expense of being a member of a number of such bodies is considerable and is a serious item to a large number of us; this is partly caused by their complete independence of each other. Some independence, especially in the details of policy, is essential, but collaboration in office and routine work will be economical, and some further measure of collaboration in publication may still be found to be possible.

You, who include manufacturers, teachers, engineers, consultants, works chemists and other research chemists, form the most powerful organisation for whose help we appeal. The provision of a large fund is of prime importance and the members of this Society will, I know, do their utmost, not only for the sake of the science in which we are interested, but out of a sense of pride in the Society which we have founded and to which we are so attached. It is our duty to set an example, and I have every confidence that we shall do so. It may be worth while considering whether the Federal Council might organise local committees in some places to discuss the best means of raising money in the locality. If this is done, I feel sure that the members of this Society will take an active and important part on such committees, as they always do when any question of public policy is at stake. It is my ambition that during my term as President the public spirit of this Society and its wideness of outlook will remain not only as great as in the past, but may even increase.

This address is already too long, but at this critical period for our profession I am only afraid of omitting, but never of repeating or dwelling too long upon anything which may be of the least use to our progress.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY

The following are summaries of Reports presented at the meeting of the International Union held in Cambridge, from June 16 to 20:—

SOME NEW ASPECTS OF TAUTOMERISM

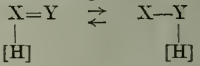
By Prof. J. F. Thorpe, C.B.E., D.Sc., F.R.S.,
and
C. K. Ingold, M.B.E., D.Sc.

This Report is a summary of certain aspects of the phenomenon of tautomerism which have been studied at the Imperial College of Science and Technology during the past few years.

The authors hold that the significance of the word "tautomerism" should not be restricted to the narrow definition originally given by Conrad Laar, but should be broadened to correspond with broadening philosophy of the subject, and modernised to keep pace with modern investigation. Thus, recommending a progressive rather than a "legal" attitude (*cf.* Lowry, *J.C.S.*, 1915, **107**, 1389), they propose that the term should apply to *all* reversible isomeric change (synonyms and qualificatory prefixes being abolished), and that it should continue to possess this significance until further discovery shows the definition unsuitable.

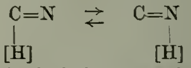
It follows from this view that the classification of tautomeric change must be based solely on *the nature of the isomerism* and not on the "one-sidedness" of the equilibria or the speed with which they are established in given circumstances. Adopting this mode of classification, the authors pass in review the various types of tautomeric change which have been the subject of recent investigations.

The Dyad Type:



$$\underset{\substack{|\\ [\mathrm{H}]}}{\mathrm{X}}{=}\mathrm{Y} \rightleftarrows \mathrm{X}{-}\underset{\substack{|\\ [\mathrm{H}]}}{\mathrm{Y}}$$

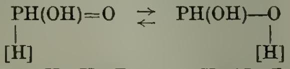
The principle example of this is hydrocyanic acid.



$$\underset{\substack{|\\ [\mathrm{H}]}}{\mathrm{C}}{=}\mathrm{N} \rightleftarrows \mathrm{C}{=}\underset{\substack{|\\ [\mathrm{H}]}}{\mathrm{N}}$$

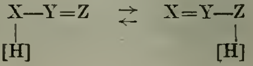
the equilibration of which has recently been investigated by (Miss) E. H. Usherwood (*J.C.S.*, 1922, **121**, 1604) by a method depending on the measurement of the thermal effect arising from the shifting of the equilibrium with changes of temperature. It has been shown in this way that the vapour consists of an equilibrium mixture containing a great excess of formonitrile, the proportion of carbylamine being of the order of 10^{-3}.

The case of hypophosphorous acid (A. D. Mitchell, *J.C.S.*, 1923, **123**, 629) is also referred to:—



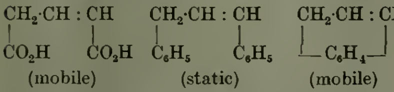
$$\underset{\substack{|\\ [\mathrm{H}]}}{\mathrm{P}}\mathrm{H(OH)}{=}\mathrm{O} \rightleftarrows \mathrm{PH(OH)}{-}\underset{\substack{|\\ [\mathrm{H}]}}{\mathrm{O}}$$

The Triad Type:



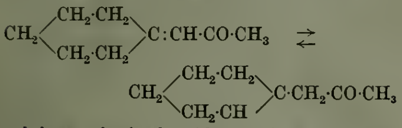
$$\underset{\substack{|\\ [\mathrm{H}]}}{\mathrm{X}}{-}\mathrm{Y}{=}\mathrm{Z} \rightleftarrows \mathrm{X}{=}\mathrm{Y}{-}\underset{\substack{|\\ [\mathrm{H}]}}{\mathrm{Z}}$$

The special section of this subject in which new work has been carried out is that relating to "three-carbon" systems (*i.e.*, systems in which X, Y and Z all represent C atoms) (see below). But there is a point of general application on which stress is laid, namely, that the existence of a triad system does not necessarily imply tautomeric mobility; thus benzylidenebenzylamine, containing the system C[H]·N : C, is static. That the character of the groups attached to the terminal atoms of the system plays an important part is shown by the following instances :—



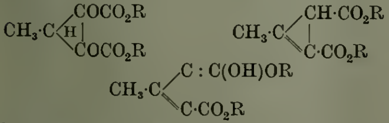
but no similar evidence at present exists which shows that the group attached to the central atom of the system is of like importance (Ingold and Piggott, *J.C.S.*, 1922, **121**, 2381; 1923, **123**, June). The probable reason for this is given by E. H. Usherwood (*J.C.S.*, 1923, **123**, July).

Birch, Norris and Kon have investigated a case of three-carbon tautomerism :—



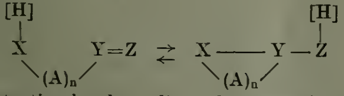
and have obtained evidence of the existence of a mobile equilibrium at the ordinary temperature (*J.C.S.*, 1923, **123**, June).

The question of the existence of normal forms of the glutaconic acids has recently been advanced by the isolation of a form of the methylcyclopropenedicarboxylic esters which conventional modes of formulation cannot accommodate (Goss, Ingold and Thorpe, *J.C.S.*, 1923, **123**, 327) :—

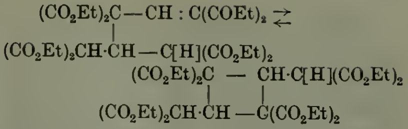


Geometrical isomerism is not possible in the cyclic structure, and thus the only concrete alternative at the disposal of those who disbelieve in what has come to be called "co-ordinated" hydrogen fails to apply.

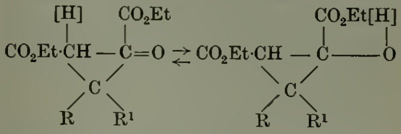
The ring-chain type :—



Attention has been directed to several types of ring-chain tautomerism. Ingold, Perren and Thorpe made a close study of certain instances in which X, Y, and Z are all carbon atoms :—

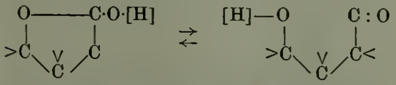


(*J.C.S.*, 1922, **121**, 1765), whilst cases in which X and Y are carbon and Z is oxygen :—

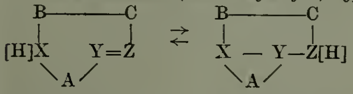


have been dealt with by Thorpe and his collaborators in a long series of papers, in which, in particular, the influence of the groups RR¹ is studied.

In another important type of ring-chain tautomeric change X and Z are both oxygen and Y carbon. It was first suggested by Jacobsen and Stelgner (see Meyer and Jacobsen, *Organische Chemie*), and has recently been shown by dynamical experiments carried out in this laboratory, that this change is at the basis of the mutarotation of the sugars :—

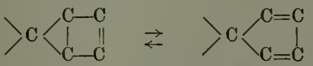


The intra-annular (*mobile hydrogen*) *type* :—

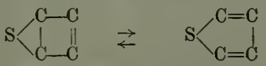


The evidence that α-campholytic acid conforms to this type is reviewed and discussed

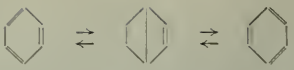
The intra-annular (*no mobile hydrogen*) *type.*—The chemistry of the bridged five-carbon rings which have recently been under investigation in the South Kensington Laboratories is reviewed, and is shown to be explicable only on the assumption that a condition of tautomerism exists between bridged and double-bonded isomerides :—



(Farmer and Ingold, *J.C.S.*, 1920, **117**, 1362; Farmer, Ingold and Thorpe, *J.C.S.*, 1922, **121**, 128). On account of the stability and tendency to formation of these substances it is suggested that the intra-annular tautomerism of thiophen is of a similar character :—



and that the nuclear vibrations of benzene are a development rendered possible by the greater molecular symmetry :—



This view has been supported by an examination of the properties of aromatic compounds themselves (Ingold, *J.C.S.*, 1922, **121**, 1133), by showing that the bridged structure produced by synthesis cannot be distinguished experimentally from ordinary aromatic structure (*loc. cit.*, p. 1143), and by showing that compounds of the five-carbon ring type simulate aromatic character to a remarkable degree if certain conditions relating to the stability of the bridged phrase are satisfied (Ingold, Seeley and Thorpe, *J.C.S.*, 1923, **123**, 853).

CONTACT CATALYSIS

By E. K. Rideal, M.B.E., M.A., D.Sc., Ph.D.

During the last few years numerous writers have entered the field of contact catalysis. The progress to be recorded in the visualisation of the mechanism of such reactions is slight, but none the less definite.

It is now generally conceded that contact action is no misnomer and that the reactants are adsorbed on the surface of the catalyst which does not exert any action by radiation at a distance. Doubtless at high temperatures there is an extended range of action due to electron emission.

The conception, postulated by Hardy and Langmuir, that adsorption of reactants occurs in monomolecular and orientated films, has been used successfully in interpreting a great number of gaseous catalytic reactions and is slowly being extended to reactions occurring in liquid media by van Kruyt for the surface of charcoal, and Hopkins at the surface of an enzyme, oxidase, present in liver tissue. The phenomenon of hydrogenation at colloidal palladium surfaces appears also to be amenable to the same interpretation. Easily liquefiable gases are certainly adsorbed in polymolecular layers at ordinary pressures, but no evidence of catalytic action in any but the first layer is at present forthcoming.

Attempts to elucidate the reasons for the variation in the catalytic activities of solid catalysts have revealed a number of possible variables ; the adsorption of the reactants in a suitable ratio, the adsorption of the reactants in suitably orientated positions, the spacing of the lattice work of the solid, and the activity of the complex catalyst reactant. Unless the first three factors are determined precisely it is difficult to evaluate the activity of the complex in terms of the critical energy increment. The function of the promoters in affecting catalytic activity is evidently more complex than was originally considered. In certain cases, *e.g.*, sodium carbonate in the presence of oxides and some metals, it affects specifically the reaction velocity of one reaction by the selective adsorption of one reactant, or product of a reaction. In other cases, *e.g.*, palladium platinum mixtures in hydrogenation, it apparently augments the active catalytic area by a species of peptisation. No case of selective activation apart from selective adsorption has yet been realised.

Recently two cases of a new species of promoter action have been established. Oxygen adsorbed by sulphur promotes the hydrogenation of sulphur, and a palladium copper mixture promotes the selective combustion of carbon monoxide in hydrogen. It appears certain that the juxtaposition of a foreign atom in the surface of an otherwise homogeneous material affects its neighbours. Many cases of such interphasial action confirm this action: thus calcium carbonate only undergoes decomposition at the $CaCO_3$–CaO interface. Copper oxide undergoes reduction only at the CuO–Cu boundary.

Experimental work on the nature of adsorption compounds which undergo catalytic change is proceeding in various directions. Accurate measurements of the primary and secondary adsorption of the reactants has been extended in the case of gases on metals and oxides, which will doubtless be extended shortly to the investigation of the adsorption of mixed gases so as to evaluate the relationship between surface concentrations and catalytic speed. More precise methods for the measurement of the heats of adsorption of gases on solids may reveal a relationship between activity and the decrease in free energy of the system. Various criteria are now available to distinguish an adsorption compound from a true chemical surface combination. If it be assumed that these criteria are valid it would appear that adsorption compounds, *e.g.*, those between carbon and oxygen, exist in different degrees of stability. The problem of quantitative measurement of the degrees of stability of such compounds still awaits elucidation.

Although support is still given by some to a purely radiation theory of surface action, the arguments against the theory in its simple form are now assuming very serious dimensions. On the other hand, the data on " quantumised " relationships are increasing in number. Adsorption compounds, if regarded as covalent compounds in which the binding electrons, one from the catalyst and one supplied by the reactants, can occupy fixed positions or more probably move in definite quantumised orbits, may supply the clue to the actual mechanism of catalytic action.

The work of Langmuir on the possibility of a connexion between catalytic activity and thermionic emission, of Haber and Richardson on electron emission in surface chemical action and of Frank on the combination of hydrogen and nitrogen effected by ionisation of the nitrogen by high-speed electrons, indicates potential methods by which the stability of the adsorption compounds might be determined in terms of radiation or ionising potentials.

THE STUDY OF SOAP SOLUTIONS AND ITS BEARING UPON COLLOID CHEMISTRY

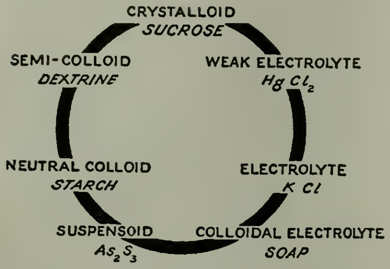
By Prof. J. W. McBain, F.R.S.

Soaps lend themselves particularly to the study of the colloidal condition. Not only are they of known chemical composition but their kinds are so numerous that almost any desired combination of properties can be obtained. Further, they typify a very great group of ionisable materials and exhibit a very close parallelism with the behaviour of the salts of protein and gelatin.

The present report deals chiefly with the properties of fluid solutions and clear transparent elastic jellies in the state of complete true reversible equilibrium. For the purpose of definition it is stated that dilute soap solutions are ordinary crystalloids, whereas more concentrated ones are colloidal electrolytes, and that if the soap is present in excess of saturation value, potassium soap separates out in the form of true crystals and sodium soap in the form of white curd fibres. The transparent jellies are confined to a portion of the region in which the soap is a colloidal electrolyte. The most concentrated solutions, or those to which much salt has been added, are those which constitute anisotropic liquids. A study of various physical properties enables the author to conclude with some confidence that the major properties of soap solutions are due to the soap itself, and not to products of hydrolysis. Two important properties of soap solutions are therefore osmotic activity and conductivity. Examination of these two properties shows that a strong solution of a higher soap may be said to exhibit one half the osmotic activity of an ordinary salt. This activity increases in dilute solution and diminishes with rise of temperature, intermediate values being shown by various solutions with regularity. The conductivity is shown to be equal to that of a salt. It is concluded that one half the conductivity of a soap solution is due to a negative carrier which does not exhibit osmotic activity and is therefore colloidal, *i.e.*, the ionic micelle. A colloidal electrolyte is a salt in which one of the ions is replaced by ionic micelle; that is, highly charged and solvated colloidal particles. The undissociated colloidal electrolyte consists of neutral micelle. From this, definite values can be calculated for the concentration of each of the constituents of the solution such as sodium ion and ionic micelle, and the mobility and equivalent conductivity of the latter directly follows. From a study of further evidence it is concluded that the ionic micelle must contain a certain amount of neutral colloid, although, on the other hand, there is evidence that much of the latter exists independently as neutral micelle. The chief difference between potassium and sodium soaps, and also between the saturated and non-saturated homologous series, is not due primarily to differences in the constitution of their solutions, but rather to the very great difference in solubility, the highest saturated sodium soaps being practically insoluble at room temperature, although all are extremely soluble at the boiling-point. The following theoretical consequences are arrived at:—It is thus established that true, complete reversible equilibrium can subsist in a colloidal system between all the various crystalloidal and colloidal constituents. There is here clear proof that the colloidal particles are definite stable aggregates in true equilibrium with their crystalloidal components. The unit is the colloidal aggregate, not the molecule or simple ion, the aggregate being large enough to be held back by an ultra-filter which allows the molecule to pass through. Much evidence is available that colloidal electrolytes constitute an enormous class of substances occurring both in aqueous and in non-aqueous solutions, being particularly important in the latter. The characteristics of this class are essentially the occurrence of poly-molecular aggregates and ionic micelle. Colloidal particles may conduct better than true ions, but it is not mere electrophoresis that is meant. The actual conductivity of one ionic micelle containing, say, ten palmitate ions, is 20 or 30 times greater than that of a single palmitate ion, so that the equivalent conductivity of the ionic micelle is still several times that of the simple fatty ion. Consideration of the relationship between a particle of ionic micelle, which is revealed by its high conductivity and the corresponding sodium or potassium ions, leads to a modified picture of the electrical double layer and the phenomena connected therewith. It is obvious that the electrical conductivity of these ions and charged surfaces is not impaired by their participation in an electrical double layer. The study of various organic derivatives, such as sulphonates, shows the importance of long molecules, in the formation of colloidal electrolytes and jellies as well as crystalline liquids.

The discovery of the ionic micelle, the extreme type of a fully charged colloidal particle, the transition through the slightly charged suspensoids to the other extreme of neutral colloids, such as rubber in benzene or nitrocellulose in non-ionising solvents. It is clear that the existence and stability of such neutral colloids is almost or quite independent of electrical charges, and that solvation is the key to their behaviour. The diagram on the next page suggests a rational classification of all solutions, showing the gradual transition between each pair of neighbouring types.

Soap in colloidal solution is hydrated, and the method used is of general applicability in colloid chemistry. It consists in ultra-filtration of a sol to which an indifferent reference substance has been added; the filtrate is more concentrated as regards reference substance than the original sol, and from this the amount of solvent held back in combination with the colloid is calculated. The salient facts observed by Miss Laing in her work on the properties of soap jellies are the following:—The conductivity of a soap solution is quantitatively unaffected when it sets to a clear, transparent elastic gel. The same is true of its osmotic activity, and of the concentration of sodium ions measured by sodium electrode. Indeed, the only difference between sol and gel appears to be the mechanical rigidity and elasticity of the latter. Neither shows any structure in the ultra-microscope. During electrolysis the relative movement of the constituents of the solution is independent of whether it is a clear, elastic jelly or a fluid sol.



The identity of the significant properties of sol and gel proves that the same equilibria exist in each. The colloidal particles in sol and gel must be identical in kind and amount. The unchanged conductivity shows that the process of electrical conduction is unchanged in kind and degree. The "electrolytic migration" in soap solutions is identical with "electro-osmosis" of water through a transparent soap jelly, and with the "electrophoresis" of pieces of soap jelly suspended in a soap solution. The identity of conductivity of sol and gel is particularly significant in discussing the structure of gels. Any theory conflicting with this is evidently untenable, as for instance, Wo. Ostwald's and M. H. Fischer's suggestion that gelatinisation is due to reversal of phases. Some miscellar theory of gels is clearly indicated. In the case of soaps the structure is probably filamentous.

Thus, although soaps, proteins, etc., are commonly called emulsoid colloids, they cannot be regarded as emulsions. Evidence indicates that the colloidal unit is an aggregate of molecules, and that these colloidal units persist and retain their identity in larger structures, such as gels and coagula. This behaviour appears to be general; compare, for instance, the study of particulate clouds (aerosols). The apparent viscosity of such systems as soap and gelatin solutions has no marked effect upon electrical conductivity; the viscosity of a soap sol may be altered a thousandfold or it may be solidified to a clear elastic jelly without affecting the molar conductivity.

The work on the properties of soap curds shows, principally, that there is a sharp distinction between true soap jellies and the soap curds with which they have been commonly confused. Gelatinisation is not a process of crystallisation in the sense of removal of colloidal particles from the sphere of action of the solvent; whereas the formation of curd or coagulum involves this separation. Presumably, jellies in general should be distinguished from coagula.

One result from this work on surface concentration of soap and other solutions requires to be mentioned. The surface tension of water is lowered by about 60 per cent. in a very dilute solution (about $N/1000$); and on further addition of soap the surface tension is not further diminished, but rather increases very slightly. According to Gibb's adsorption equation, there should be a deficiency of soap in the surface of solutions of ordinary concentration. Actually there is an accumulation in the surface which is not due to chemical decomposition. It seems to be the actual lowering of surface tension and not the slope of the surface-tension curve which governs the occurrence of adsorption. A modified formula based on the actual lowering of surface tension would appear to be more nearly in accord with all the known facts.

Only a few aspects of this vast subject have been adequately investigated; but it appears that its exact elucidation, so necessary to place the soap industry on a scientific basis, will also have a bearing upon a surprisingly large number of theoretical considerations.

PHYSICAL AND CHEMICAL SURVEY OF THE NATIONAL COAL RESOURCES

In pursuance of the policy of carrying out the work of the above survey with the help of local committees, the Fuel Research Board has appointed a committee to deal with the physical and chemical survey of the coal seams in the South Yorkshire area.

The composition of the committee is as follows: Mr. J. Brass, Mr. Robert Clive (hon. secretary), Mr. H. Danby (representing the South Yorkshire Coal Trade Association); Lieut.-Col. H. Rhodes, M.Inst.C.E., M.I.Min.E., F.S.I. (representing the Midland Institute of Mining, Civil and Mechanical Engineers); Prof. R. V. Wheeler, D.Sc.; Mr. C. H. Lander, D.Sc., M.I.Mech.E., A.M.Inst.C.E., Director of Fuel Research (chairman *pro tem.*) (representing the Fuel Research Board); Mr. Walcot Gibson, D.Sc. (representing the Geological Survey of Great Britain).

The first of these committees has now been actively at work in the Lancashire and Cheshire area for nearly eighteen months.

CHEMICAL JOURNALS IN JAPAN

By AKIRA SHIMOMURA

Anybody who has a faint idea what Japanese letters are like would be interested to know that in Japan several journals are published in Japanese for the advancement of chemistry, among which the following three may be counted as the most prominent :—

(1) *Nippon Kwagaku Kwai Shi* (Journal of the Chemical Society of Japan, formerly Journal of the Tokyo Chemical Society). This journal is published monthly by the Chemical Society of Japan, and is distributed among its members, whose number is given as 1122, and is intended as the medium for publication of original researches. It is rather interesting to know that the first volume appeared 44 years ago, only 12 years after the Deutschen Chemischen Gesellschaft was founded. The society holds scientific meetings periodically, and an annual meeting in Tokyo very much after the style of the Chemical Society of London.

This year the annual meeting was held in the Chemical Department of Tokyo Imperial University, on April 7 and 8, and 42 papers were read. Some of the titles of papers are given hereunder to give, as far as possible, a general idea of the nature of the investigations carried out :—

Vapour density of acetylene.
Catalytic action : Catalytic formation of cymene ;
 Catalytic reduction of methyl-naphthalyl ether.
Preparation of benzoin substitution products.
On amino acids and aldehydes.
Synthesis of indolketonic acids.
Metallographical investigation of sewing needles.
Copper-zinc system, containing 40-100 per cent. of copper.
Chemical investigation of Japanese minerals containing rare elements.
Chemical investigation of Japanese woods.
Estimation of sulphur in iron.
On analysis of elements of platinum group.
The nutrient value of condensed milk.

(2) *Yakugakuzasshi* (Journal of the Pharmaceutical Society of Japan). This monthly journal was started three years after the Journal of the Chemical Society of Japan, and is intended mainly for publication of papers relating to pharmacy and organic chemistry, and seems to be widely distributed among its members, numbering 3761, and including many apothecaries—a term which seems to sound more reasonable than "chemists," as they are called in England. The latest number contains the following communications :—

Some derivatives of indol.
Chemical constituents of Chinese "Hsing-chuang."
Rupture of furfuran nucleus.
On a new pulveriser.

(3) *Kogyo-Kwagaku Zasshi* (The Journal of Chemical Industry). The Society of Chemical Industry of Japan, having 3067 members, is much younger than its English brother, counting only 26 years from its birth. Its Journal consists of three sections,—*i.e.*, transactions, abstracts and reports, dealing chiefly with the industrial side of various branches of chemistry. In the latest number the following communications are found :—

Study of the ternary alloys of aluminium, copper and magnesium.
The manufacture of acetaldehyde from acetylene.
Heat value of bituminous coal.
The action of ultra-violet rays on raw rubber in an atmosphere of carbon dioxide.
Formation of petroleum hydrocarbons from turpentine oil.
The properties of Tsubaki oils from Nagasaki and eight other prefectures.
Liver oils from *Stereolepis ishinagi* and *Erilepis zonifer.*
Inquiry into the study of the manufacture of artificial petroleum for industrial purposes.

Besides these more academic periodicals, there are several popular scientific magazines which contain a good many chemical articles, some being miniatures of *Nature* or *Chemical Age*, and others an imitation of *Discovery.*

All these journals are, of course, written in Japanese, except (2) and (3), which have short abstracts of the original papers in either English or German in the same number. Although I am not inclined to say anything against our own language, I have to admit that Japanese is not a language suitable for scientific statements in general ; for instance, there are no articles, no distinctive difference between singular and plural, and the construction of our language necessitates explanatory phrases to be put before the noun. The difficulty arises in the nomenclature of organic substances. In fact, it is almost arbitrary according to authors, some using German pronunciation, and others English, although it is not exactly what it should be. It wants not a little practice to see the identity of "benzylacetonephenylmethylhydrazone" and "benchiiruasetonfenirumechiruhidoratsuon," as it is reproduced in Japanese characters, and which the editor of *Punch* might accept as a contribution.

It is rather interesting to note a tendency of late to publish the results of chemical researches in foreign languages, English, German or French. In this connexion the publication of the following new journals may be cited: *Japanese Journal of Botany, Acta Phytochimica* (which have been noticed in *Nature*, Dec. 30, 1922), *Japanese Journal of Chemistry* and the *Journal of Biochemistry.* They accept communications only in English, German or French, so that our European and American friends may be able to read the original papers of Japanese workers without depending on so-called abstracts, which are always very unsatisfactory and sometimes unreliable.

Apart from these regular periodicals, Science Departments of most Universities have their own Reports or Memoirs, which are, as a rule, published in foreign languages, either English or German. It is deemed an honour to have some work published in these University

Reports, as the publishing fund is rather restricted in each University. The Institute of Physical and Chemical Research, which was organised during the war by Governmental initiative, and very much resembles the British Department of Scientific and Industrial Research in its scope, also issues its reports in English.

Personally, I wish this tendency to use foreign languages, especially English, which is undoubtedly more suitable for scientific communication, as a medium of publication will grow stronger, and the three bigger journals mentioned above will ultimately take this step some day.

ITALIAN MINERAL OUTPUT IN 1922

The official statistics of the mineral and metal output in Italy in 1922 are given in the following table :—

	Metric tons		Metric tons
Minerals :—		*Minerals :—*	
Iron ore	416,400	Boric acid ..	2,500
Manganese ore ..	10,400	Graphite.. ..	7,300
Copper ore ..	7,134	Pumice stone ..	21,600
Lead-silver ore ..	28,027	Asbestos ..	500
Zinc ore	86.266	Steatite and talc	25,000
Gold ore	340	Barytes	19,000
Nickel ore ..	25	Coloured earths..	8,400
Antimony ore ..	495	Quartz and feldspar	27,300
Lead-zinc ore ..	180	Porcelain clay ..	7,600
Lead-zinc-copper ore	250	Refractory materials	44,900
Iron and cupriferous pyrites..	496,500	Siliceous sand ..	185,000
Mercury	1,530	Fluorspar ..	1,700
Anthracite ..	26,190		
Coal	171,730	*Metallurgical Products :—*	
Lignite	704,600		
Peat	61,500	Pig iron	77,000
Sulphur, raw ..	171,800	Pig iron, synthetic	14,400
Sulphur ore, ground ..	19,800	Steel ingots, etc.	943,000
		Alloys, metallic..	22,000
Salt, rock ..	49,100	Copper	—
Salt, medicinal ..	47,300	Lead	10,500
Petroleum ..	4,300	Silver	6,700
Asphalt and bituminous rock ..	66,200	Gold	9
Raw bitumen ..	700	Zinc	3,060
Bauxite	65,600	Antimony ..	200
		Aluminium ..	630

The output of iron ore shows an increase of 50 per cent. compared with the previous year, but is only one-third of the pre-war production. The present output of copper compares very unfavourably with the pre-war outturn of 89,000 tons, but owing to the accession of Istria, the production of mercury and bauxite has increased considerably ; it appears that a fair export trade in bauxite is being developed. A collapse in the sulphur industry was averted with Government help, and the agreement recently concluded with American interests should prove of considerable benefit (*cf. Chem. & Ind.*, 1923, p. 375).—(*U.S. Comm. Rep., April* 16, 1923.)

PERSONALIA

It is announced officially that the Lord President of the Council has accepted, with much regret, the resignation of Sir George Beilby, F.R.S., after nearly seven years' voluntary service as Director of Fuel Research, and Chairman of the Fuel Research Board under the Department of Scientific and Industrial Research. Sir George Beilby retains his membership of the Advisory Council of the Department, and has consented to act as Honorary Adviser to the Board. Dr. C. H. Lander has been appointed Director of Fuel Research, and Sir R. Threlfall, F.R.S., a present member of the Board, its Chairman. The following have accepted appointment as additional members of the Fuel Research Board:—Mr. R. A. Burrows, Sir John Cadman, K.C.M.G., D.Sc., Dr. Charles Carpenter, C.B.E., Mr. Samuel Tagg, Prof. Sir James Walker, F.R.S., and Prof. R. V. Wheeler, D.Sc.

Mr. E. A. Pinchin, B.Sc., F.I.C., has been appointed Public Analyst for the City of London, in place of Dr. F. L. Teed, F.I.C., who has retired after many years' service.

Sir E. Rutherford, F.R.S., has been elected an honorary foreign member of the Washington Academy of Sciences.

The following officers were elected by the American Institute of Chemistry for the ensuing year : President, Horace G. Byers ; Vice-president, Lloyd Van Doren ; Treasurer, Clarence K. Simon ; Secretary, Lloyd Lamborn.

Dr. E. G. Acheson has been elected an honorary member of the American Electrochemical Society in recognition of his many inventions in the field of electrochemistry.

* * *

With regret we announce the death of Mr. G. A. Boeddicker, managing director of Henry Wiggin and Co., Ltd., of Birmingham. Mr. Boeddicker, who was an authority on nickel and cobalt, was one of the founders of the Institute of Metals.

FORTHCOMING EVENTS

June 25.	THE INSTITUTION OF THE RUBBER INDUSTRY, at The Engineers' Club, Coventry Street, Piccadilly, W. 1, at 8 p.m. "Some American Rubber Manufacturing Problems," by Dr. W. C. Geer.
June 25-30.	THE INTERNATIONAL AIR CONGRESS, LONDON, 1923. Opening Ceremony by His Royal Highness the Prince of Wales at the Institution of Civil Engineers, and Inaugural Address by His Grace the Duke of Sutherland. Numerous papers will be read; Receptions will be held by the President (the Duke of York), the Lord Mayor of London, and the Duke of Sutherland; and the proceedings will terminate with a banquet at the Hotel Victoria, S.W. 1.
June 28.	THE INSTITUTION OF ELECTRICAL ENGINEERS. The annual conversazione will be held at the Natural History Museum, South Kensington, S.W., at 8.30 p.m.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinions by his contributors, but it must be understood that he does not necessarily agree with them.

Meetings

of all kinds are coming on us fast and thick. The International Mining Exhibition is only just over, and the International Conference of Pure and Applied Chemistry precedes the Annual General Meeting of our own Society at Cambridge. Dr. Armstrong and Dr. Charles Carpenter are sure to deliver most stimulating addresses at Cambridge, as they are both not only distinguished scientists, but also hold commanding positions in the industrial world. It is to be hoped that their addresses will be widely quoted in the daily Press so that the public may get to know at least something of the aims of chemistry and chemical industry.

A Quarter of a Century

ago the genius of Herman Frasch brought about the initial steps which have resulted in the transfer of the centre of gravity of the sulphur market of the world from Sicily to the United States of America. At that time an English Company, the Anglo-Sicilian Sulphur Company (formed in 1896) controlled the sulphur market of the world, but this Company soon recognised the great importance of Frasch's process of extraction, and retired from the field at a moment which was most suitable and beneficial to the interests of all connected with them. The sale of sulphur in Sicily then passed into the hands of a compulsory selling agency, the Consorzio Obbligatorio, initiated by the Italian Government, and this agency became by law the sole purchaser of crude sulphur from the Silician sulphur mines, and also the sole seller of crude Sicilian sulphur throughout the world. The Consortium was originally established for a period of twelve years, but before the first period elapsed an extension over a further twelve years had been decided upon, and, therefore, at the present day the visible life of the Consortium extends until 1930.

The American Sulphur Producer

during the whole life of the Consortium has been gaining ground at the expense of the Sicilians, and shortly after the termination of the war the Sicilian industry found itself in a lamentable condition, and had to seek the financial aid of the Italian Government. The reason for the financial difficulty was not far to seek. The artificial prosperity occasioned by the war had suddenly ended, large stocks of unsold sulphur existed at the ports, and the financing banks, having issued loans against these stocks during the period of prosperity, found that their security was rapidly decreasing in value, and that the sale of sulphur was also rapidly decreasing. In these circumstances the Government agreed to guarantee both the capital and interest of a loan which is shortly to be issued in the shape of debenture bonds for 120,000,000 lire, whereby the sulphur industry will be able to meet its liability to the banks with sufficient margin over to afford some capital for carrying on operations. During this period of difficulty, on the other hand, the American sulphur producers had done much to perfect their process, and although they also found themselves with large stocks which were not readily realisable, nevertheless their position was a very much stronger one.

Two Definite Results

follow from these factors. I hear that the American mine owners have united together to form a common selling agency for all sulphur sold outside the U.S.A., and that an agreement has been reached between the Americans and the Italians with regard to future sales of sulphur. The agreement gives the Mediterranean market to the Italians, which means they will have altogether an annual sale of about 250,000 tons of sulphur.

Professor Dreyer,

whom I met the other day, has now given to the world the results of his work on new principles in bacterial immunity. This work may have a far-reaching effect on the treatment of tuberculosis. The *Bacillus tuberculosis* is one of the germs which surround themselves with a fatty or waxy sheath. Professor Dreyer has produced a method of defatting the germs and at the same time killing them. The treatment of tuberculosis with defatted germs appears to be a great advance in our knowledge of this subject.

"Defatted"

is an ugly word, and I was interested to hear a number of philologists after dinner attempt to find a substitute. I do not think anything very useful was suggested on that evening, but since then it has been suggested to me, and I pass the suggestion on to Professor Dreyer, that a better word would be "desebate." At any rate the word sounds better, although I am not quite sure whether it is equally correct.

The Disease of Leprosy

is another ill which flesh is heir to and which our medical scientists are taking steps to overcome. I anticipate that at the International Leprosy Congress which is being held at Strasbourg next month the matter is to be discussed. We are fortunate in Europe in having a relatively small number, and the preparations of chaulmoogra oil which have been used in India have attained a large measure of success. The trouble with this disease, as with so many others, is that the victims will not come forward in its early stages.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL GENERAL MEETING,

CAMBRIDGE, 1923

By the time this issue has reached the hands of our readers, the business part of the Annual Meeting will be over, and those who have been able to be present will have heard Dr. E. F. Armstrong deliver his Presidential Address and have attended the receptions held by the Vice-Chancellor of the University and by the President and Mrs. Armstrong, in the Fitz-William Museum and the Guildhall, respectively. Still to come are the presentation, on Friday morning, of the Society's Medal to Dr. Charles Carpenter, who will then deliver an address on the subject of "The Evolution of a Chemical Industry"; the address by Dr. F. W. Aston, F.R.S., on "Isotopes," on Friday afternoon; and the trip to Ely Cathedral on Saturday.

As *Chemistry and Industry* has to go to press before the Meeting commences, a description of the proceedings must be postponed to a later issue. But for the convenience of those who have been prevented from attending the Meeting, it has been decided to publish the Presidential Address in this issue (*cf.* p. 603).

Sir W. J. Pope, K.B.E., F.R.S.

In former years the Society has met in industrial localities, where it was possible to visit factories representing branches of chemical and allied industries, where methods of production of varied kind could be inspected and discussed. It is true that Cambridge offers no attractions of this severely practical nature, but its significance to the members of the Society of Chemical Industry is none the less real. Since the far-off days when the town of Cambridge was a chief centre of English trade and commerce, trading with Northern Europe by means of the ships of the Hause towns and of Flanders, the University has grown—at times sluggishly, with animation almost suspended—until at last, now that the study of the humanities, so long dominant, has taken a more proportionate place in education, Cambridge has come to possess one of the foremost Schools of Chemistry, a school which provides training for more than 700 students. In such surroundings the addresses of Dr. Armstrong and Dr. Carpenter must take on special significance, all the more because, as the President points out, the time is now come for educational and industrial authorities to confer and decide what kind of training will produce the type of man wanted in industry—a most difficult question. This question of paramount importance is being discussed at large in England by other professions besides our own; that such discussion is needed once more emphasises the fact that in this country we have no general or national scheme of education. Nor have we an exact notion of the meaning of the term, some considering it to imply "mental discipline"; others the acquisition of "useful knowledge." But the British nation possesses a genius for practical life, and it is therefore essential that our educational system should be properly and adequately correlated with life. It has been said that a "haziness of intellectual vision is the malady of all classes of men . . . . who have not had a really good education." Dr. Armstrong once again utters the warning that

King's Parade

whereas a chemist obtains his first appointments on the basis of his professional qualifications, afterwards he succeeds because of his ability as a man. Education, then, from this standpoint, should consist in guiding the student in the acquisition of experience, whether experience of the properties of matter or—most valuable of all—experience of human relations gained by contact with fellow-beings in lecture theatre, where he is introduced to the thoughts and discoveries of the great men of the past, in laboratory, where he can put those discoveries to test, in playing fields, in social intercourse. Having had the right kind of education, the scientific worker should possess an intellectual clarity that should enable him to probe deeper, more subtly, into the reactions he must investigate, and whether his work lies in the industrial field or in the academic laboratory, it requires for completion the insight that intellectual clarity alone can give.

It was natural that an address to be delivered in Cambridge should consider the subject of education ; and it is to be hoped that the President's proposal for a conference with the teachers will be quickly acted on. At a meeting following so close on the heels of the International Conference of Pure and Applied Chemistry, it was to be expected that reference should be made to the necessity—still, unfortunately, as urgent as ever—of instilling into the public mind a clearer notion of the true meaning of the terms "chemist" and "chemistry." But, before chemists can bring their full influence to bear on public matters concerning the profession, they must perforce unite so that they can speak with no dissentient voice. Much still remains to be done before Chemistry House, the symbol of the underlying unity of the profession, can become a reality. The President has given the lead, and it remains for the members of the Society to act individually to insure the full fruition of their common aspirations.

St. John's College

The meeting at Cambridge will undoubtedly furnish the material for pleasant as well as stimulating memories in the minds of those who were present. The charm of the historic colleges and buildings (of which a few photographs are reproduced in this issue), the delightful surroundings, the venerable associations of Ely, all so impregnated with the fibre of history, will find due appreciation ; indeed, like the hospitality traditionally associated with the older Universities, they require no comment. Whatever may be the outcome of this Annual Meeting, it should at least have the result of steeling the determination of every chemist to help in raising his profession to the dignified rank which it should and must occupy.

Trinity College

MEETINGS OF OTHER SOCIETIES

ROYAL MICROSCOPICAL SOCIETY

Prof. A. Hutchinson presided over the meeting held on May 30, and Mr. H. B. Milner read a paper on "The Microscopical Investigation of Sands for various Industrial Purposes."

The paper discussed the application of the petrological microscope to the investigation and discrimination of sands and allied rocks suited to particular industrial requirements ; these included glass manufacture, ferrous and non-ferrous founding, silica-brick manufacture, scouring sand, sand-blasting, cement, mortar, concrete, brick and tile production. He also dealt with sands and gravels as a source of economically valuable minerals such as monazite and thorianite for the production of incandescent gas-mantles, tantalite for filaments, etc., and as a source of gem-stones, and showed to what extent the microscope could be employed as a rapid and economic means of studying the raw materials involved in each case. He contrasted the technical and popular conceptions of the term "sand" and then traced by means of a large series of lantern slides of photo-micrographs the distinctive characteristics of sands suited to the varied purposes mentioned above. This application of the microscope is still unappreciated by many manufacturers, some of whom, as was evident from the interesting discussion which followed the reading of the paper, were still labouring under difficulties which the aid of the microscope might lessen considerably or possibly overcome altogether. The author suggested several lines of research which could profitably be undertaken by microscopists in conjunction with manufacturers for the benefit of all those industries depending on the use of refractories. Silica-bricks, to mention one instance, lend themselves admirably to this type of analysis, both as regards their initial ingredients, their properties after being fired for different periods, and then again after prolonged use in metallurgical furnaces. In a similar way, much light is thrown on the problems presented by mortars and concretes, the internal structures of these materials frequently affording clues to inefficiency or inherent defects difficult to diagnose without the help of the microscope.

ACADÉMIE DES SCIENCES

At the meeting held on May 22 a paper by Chief Engineer Dumanois, communicated by M. Koenigs, gave an account of the results obtained with a motor fuel consisting of a mixture of 70 per cent. of alcohol (99·5°) and of 30 per cent. of paraffin oil. A fuel consumption was recorded of 10 litres per 100 kilometres for an average speed of 40 kilometres per hour. Prof. C. Moureu presented a note on work carried out with M. Dufraisse, which described their new device for estimating the water capacity of a calorimeter without the necessity of carrying out any electrical measurement; the device also eliminating thermometric errors.

On May 28 Prof. Lindet presented a paper by Prof. Stocklasa of Prague. By comparing the analysis of caliche with that of red and grey volcanic ash, the author claims to have discovered the true origin of the Chilean nitrate deposits. According to Prof. Stocklasa, Chilean nitrate has not been formed by the decomposition of organic matter, but to the transformation of the large quantities of ammonium chloride which impregnates the ash of Chilean volcanoes, bacterial nitrification of which had been intensified by radioactivity.

On June 4 M. D. Berthelot communicated a paper by M. Gantrelet on a new organic derivative of phosphoric acid and of methyl salicylate which possesses valuable properties as an analgesic and febrifuge. M. Lindet announced that M. Kayser had obtained methyl alcohol by fermenting calcium lactate, thus providing confirmation of the hypothesis that in fermentation lactic acid is an intermediary product between sugar and alcohol. M. G. Bertrand and Mlle. Benoist described the action of acids on cellulose. The final product of the reaction was glucose, but the authors claimed that the transformation is progressive, as they have discovered a new sugar with composition and properties intermediate to those of cellulose and glucose. The new sugar, "procellose," is changed successively into cellose and glucose when heated in slightly acid solution.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on June 14, 1923, Sir Max Muspratt, Bart., presiding.

After disposing of various routine matters the Council discussed the recent action of the French Authorities on the Ruhr in commandeering a large quantity of German dyestuffs and its probable effect, not only on the dye industry in this country, but on the chemical industry generally. It was decided to make strong representations to the Board of Trade, the Foreign Office and the Dyestuffs Licensing Committee on the subject.

The General Manager reported that he had been requested to "broadcast" information relating to the chemical industry with the view to enlightening the public upon its importance. The Council was of the opinion that "broadcasting" would be a very useful means of propaganda and authorised the General Manager to supply such information as he deemed desirable.

Reference was made to the Tariff of the United States of America, especially to the powers vested in the President enabling him to revise the Tariff on a recommendation of the U.S. Tariff Commission. It was pointed out that, before any recommendation could be made to the President, the Commission had to inquire into the cost of manufacture of any product, the Tariff upon which is complained of, in the country of origin. The Commission has paid a visit to this country regarding certain chemicals, and has been referred to the particular manufacturers concerned for information.

The Council was of the opinion that in all cases where information is required the Tariff Commission should be referred to the manufacturers, who should decide for themselves whether they would furnish information under conditions of secrecy. The Council thought it might be of advantage to manufacturers that the cost of manufacture should be given.

The Annual Report of the Association for the year ending May 31, 1923, was approved for submission to the Annual Meeting to be held on July 12, 1923.

CORRESPONDENCE

A PLAUSIBLE ERROR IN THE THEORY OF CO-ORDINATION

Sir,—In your issue of June 1, Mr. C. H. Spiers has interpreted correctly the views that have been developed in this *Journal* (pp. 224, 316, 412 and 462) in reference to *one* of the factors which are of importance in determining the formation of co-ordination compounds, namely, the striving of a co-ordinating metal to complete its outer shell of electrons. He has, however, suggested a modification of these views which calls for an immediate reply, since it appears to be based on ignorance of physics, rather than on knowledge of chemistry.

In an article on "Some Factors Influencing Co-ordination" (this vol., p. 319), it was pointed out that, in several of the most important series of co-ordination-compounds, "six co-ordinated groups are just sufficient in number to complete the outer shell of electrons of the metal, if each group shares one pair of electrons with the metal," but that in other series "a deficiency of 1, 2 or 3 electrons can be tolerated readily," in marked contrast with the intolerance of even a single surplus electron which is displayed in compounds such as the cobaltocyanides. Mr. Spiers proposes to halve the number of cases in which the outer shell is incomplete, by the simple expedient of stealing the two inner electrons of the K-series in order to complete the outer shell. This robbery, which is good algebra, but very bad physics, was originally devised by Eastman in the case of carbon, where, however, the chances of successful theft are much greater than in the case of manganese or nickel. The fundamental objection to all these schemes is that they neglect the known properties of the electrons, and in particular the fact that the K-electrons are held far more tenaciously than those of any other series. A well-known writer in the columns of this *Journal*, to whom this matter was referred, suggested that the proposal to remove the K-electrons, in order to enrich the L, M or N series, was like asking a gentleman, who was financially embarrassed, to part with his most essential garments, when he still possessed an opera hat and a rain-coat, which he might pawn. When this metaphor was mentioned to an eminent physicist he was emphatically of the opinion that the metaphor was nothing like strong enough to represent the tenacity with which the nucleus clings to the two electrons of the K-series, since their elimination was in fact a far more drastic operation than the mere removal of a garment.

Mr. R. H. Fowler, of Trinity College, has supplied the following numerical data, which express the reluctance of a nucleus to part with its K-electrons. The energy required to effect this separation is approximately proportional to the square of the atomic number of the element, which is a measure of the charge on the nucleus, to which the K-electrons are closely adjacent. But even in carbon, with a nuclear charge of only six, the transfer of two electrons from the K to the L series involves a fantastic expenditure of energy, many times greater than that which is rendered available by any known chemical change. These energies are usually expressed in electron-volts—that is, the energy acquired by an electron in falling freely through a given voltage. The actual energies in the case of carbon are about 230 volts to remove a K-electron, as compared with only about 16 volts for an L-electron. The latter figure would be increased by the removal of the K-electrons from the nucleus, since the electric charge on the "kernel" would be increased thereby from 4 to 6 units. Under these conditions the removal of the L-electrons might require, say, 36 instead of 16 volts. These volts can be converted into calories per gram-atom by multiplying by a factor of about 24,000. To transfer two electrons from the K-series to the L-series would therefore require $(2\times230+6\times16-8\times36)$ 24,000 calories, *i.e.*, over 6,000,000 calories for each gram-atom. In nickel the K-electrons are closely adjacent to a nuclear charge of 28 units, whilst there are 8 L-electrons, 8-M-electrons and, in a co-ordinated compound, 16 N-electrons (some of them shared) in higher energy levels. To turn a K into an N-electron would require at least 6000 volts, *i.e.*, an expenditure of energy of the order of 300,000,000 calories per gram-atom! It would be difficult to suggest any physico-chemical change that is less likely to take place; and this attempt to explain a tolerated deficiency of two electrons suggests the process of jumping from a tepid frying-pan into a particularly hot fire.

As Robinson has pointed out, there is some evidence to show that, in the hydrides of boron, the K-electrons as well as the electrons of the L-series, may be shared between two atoms, since in these compounds the boron atoms, which possess only three L-electrons each, are united simultaneously to four other atoms, but even this does not mean that the K-electrons are converted into L-electrons. In carbon, however, the compounds in reference to which this assumption is made are all unsaturated substances, in which the depleted carbon atom is linked to three other atoms only. There is, therefore, no need to assume that the K-electrons are brought to the surface, and the motive for doing this is neither chemical nor physical, but purely arithmetical. Since, however, Eastman's hypothesis provides so obvious a pitfall, I may, perhaps, be allowed to call attention to another series of phenomena in which it is directly opposed by experimentally established facts. These facts are provided by the X-ray analysis of crystals. From this point of view, the carbonate ion, CO_3'', may be taken taken as a test case on which to decide whether *eight* electrons surrounding a carbon nucleus form a depleted octet of *eight* L-electrons or a sextet of *six* L-electrons surrounding *two* electrons of the K-series. In this respect the carbonate ion may be compared usefully with the chlorate ion, ClO_3', since the chlorine nucleus is here surrounded by *eighteen* planetary electrons, and these will obviously form a complete octet of *eight* M-electrons around the *eight* L-electrons and *two* K-electrons of the inner system. Professor W. L. Bragg has supplied the information that, whilst (*i*) the three oxygens of the carbonate ion are distributed symmetrically about a three-fold axis, in a plane which also contains the carbon itself, (*ii*) the three oxygen atoms of the chlorate ion are distributed about a three-fold axis of symmetry, but do not lie in the same plane as the atom of chlorine. It is clear that the symmetry of the chlorate ion is in general agreement with a tetrahedral arrangement of four duplets of M-electrons round the chlorine nucleus; but that the configuration of the carbonate ion differs from this in just the way that would be expected if the octet were converted into a sextet. Thus six electrons may be arranged either (*i*) as a hexagon, or (*ii*) as a triangular prism, or (*iii*) as an octahedron; but if these six electrons are grouped as three duplets, each shared with an oxygen atom, it will be found that the three possible configurations all give rise to a co-planar arrangement of the four atoms, the symmetry of which would be degraded by introducing a fourth duplet. The crystallographic evidence is, therefore, in harmony with the physical evidence in repudiating the plausible scheme of robbing Peter to pay Paul. The object of this note is to warn all whom it may concern that, apart from all questions of morality, this particular form of robbery is impracticable.

T. M. Lowry

LEAD ARSENATE SPRAYS AND BEES

Sir,—The exceptional weather this year has led to an abnormal multiplication of caterpillars and other insect pests that attack the foliage and blossom of fruit trees. In consequence, the spraying of fruit trees with poisonous solutions has been very prevalent and has produced disastrous results in several directions. The British Bee-keepers' Association has recently received reports from several of its members of great mortality among bees due to the spraying of open fruit blossoms with an arsenical solution. The particular solution which appears to have caused most damage is that of arsenate of lead, which in one case caused the death of 75 per cent. of the bees in a large apiary, at a time of year when the activity of these useful insects was most essential for the fertilisation of fruit blossoms. Through the misuse of this dangerous liquid the fruit-grower not only deprives himself and his neighbours of the services of all the insects which contribute to the fertilisation of flowers and the subsequent production of fruit, but he also perpetuates and increases the very evil he seeks to remedy. The insects that are poisoned by arsenic are eaten by insectivorous birds, who themselves fall victims, and in the ensuing years the fruit-trees are deprived of their natural and best protectors. In former years, before spraying with arsenic was introduced, the failure of fruit crops through insects was not so general as it is now. In some districts the insectivorous birds are disappearing rapidly. Of seven species of these useful helpmates to horticulture in my own orchard one only is left, the blue tit. I attribute this partly to the fact that these birds hang head downwards from the twigs and thus catch caterpillars which have been sheltered underneath the leaves from the fatal spray.

It is scarcely necessary to remind the chemist that the continuous use of a combination of two cumulative poisons such as arsenic and lead in any locality may be a source of considerable danger. Worms are poisoned by the solution and, before dying, come out of their holes and are eaten by birds and poultry. Where grass grows under the trees it is covered with arsenic, and cows grazing in such orchards must produce milk which no chemist would willingly consume. In fact, an orchard continually sprayed with arsenate of lead becomes a constant and increasing source of danger to its owner and his neighbours. From the bee-keeper's point of view I approached the Ministry of Agriculture, which writes :—" The Ministry deprecates the use of lead arsenate sprays on fruit trees in open blossom, has warned growers against it by leaflets, press notices, and exhibitions and will continue to do so." The Ministry also asks for suggestions as to " any substance the smell or taste of which is especially repulsive to bees " which might be added to arsenical sprays.

Among our numerous members all over the civilised world there must be many who could help with suggestions in this matter and who have experience with non-poisonous sprays, the substitution of which for arsenic would be the best solution of the question. I understand that in the United States there are regulations limiting or prohibiting the use of powerful poisons in this haphazard way, and it is high time for steps to be taken in Great Britain to prevent selfish individuals from injuring their neighbours and probably themselves in the way they are now doing. The subject is of great importance from the point of view of the chemical manufacturer, as there is a very wide field for the use of sprays to combat the pests and parasites that seem to be an inevitable accompaniment to the growth of large areas of any kind of vegetable produce.

Walter F. Reid,
Chairman, British Bee-keepers' Association

PROPAGANDA IN GERMAN SCIENTIFIC JOURNALS

SIR,—Strange ideas seem to be abroad as to the reason why " propaganda leaflets directed against the French " as well as " some gruesome photographs " have been sent out with some German scientific journals. On inquiry, I have come to know that it is being done because the German industrial magnates want it; without their financial support publication of a journal in Germany is quite impossible.

I might mention here that the propaganda is generally against the French Militarism and not against the French as you have mentioned in last week's editorial.

I am one of those whose almost everything was destroyed by the German soldiers, but this will never make me support the Imperialist policy of my country or of her allies. I think even had the German Chemical Society sent out propaganda sheets on their own initiative—it would have been a thoroughly justifiable act; men of science have every right to resent deeds of barbarity, be they done at Louvain, Cork or Dortmund.—I am, Sir, etc.,

J. ROLAND DE CARLI

Evian-les-Bains, France

" LUCIFER " ON " CALORIFER "

SIR,—In view of the strident tone and general assertiveness of Calorifer's further letter in your to-day's issue (15th inst.), I think, perhaps, the best course for me to adopt is hereby to invite my friend, Professor Armstrong, to come and take tea with me some afternoon at South Kensington, when I will submit to him the original pressure-time records and our analyses of them, after which I feel that I can safely leave him to deal with Calorifer, so saving me much time, which can be more usefully devoted to experimental work.

I hope that in my previous letter I have made our position in the matter sufficiently clear for the present; and when in the autumn (which, by the way, is the proper time for " garnering harvests ") we publish the results of our further experiments (now practically completed) upon the influence of varying initial pressures on the combustion of carbon monoxide-air mixtures, I think we shall be able to deal with the matter in such a way as will fully prove our case, and at the same time dispose of the hasty assertions made by Calorifer. Indeed, if only he knew where and how to find it, the proof of the matter already lies in the analyses of the pressure-time records published in our recent Royal Society memoir. Doubtless your readers will agree with me in the view that persons who have thoroughly studied the original photographic records are probably in a better position to divine their meaning than an outside critic who apparently has never seen them.—I am, Sir, etc.,

WILLIAM A. BONE

NEWS AND NOTES

CANADA

The Iron and Steel Industry

During the past two decades or so, the Canadian iron and steel industry has grown markedly. In 1920, according to the Dominion Bureau of Statistics, Ottawa, the total capital invested in 1475 establishments was $642,904.322, and no less than 102,661 workers were employed. Materials utilised in 1920 cost $321,298,396. the gross value of the production being $640,233.785. The chief group belonging to these industries is that of blast furnaces and steel mills, with a capital investment of $119,761,718, and a productive value of $138,882,823. The extent of this development can be realised when it is noted that in 1900 the capital invested in the iron and steel industry was only $61,800,987, and the gross value of the production $48,271,553. Imports of iron and its products in 1921 reached an average value per month of $21,287,984, whereas the monthly exports of iron and steel goods during the same year averaged $7,942.068.

UNITED STATES

Felspar in 1921

The U.S. Geological Survey reports that the crude felspar mined and sold in the United States decreased by 32 per cent. in quantity and 27 per cent. in value to 91,865 long tons valued at $617,652. The production in 1920 was the largest ever recorded and was apparently in excess of requirements. Owing to this and also on account of the increasing output in Canada and the depressed state of the domestic ceramic industries the production of felspar in the United States in 1921 was less than normal. The supplies of felspar are made up in large part of Canadian felspar, the Canadian production in 1921 being 33,597 short tons, of which 90 per cent. was exported to the United States. The increasing production of felspar in Canada is seriously affecting the industry in the United States.

JAPAN

The Mercury Industry

Practically the whole Japanese production of mercury comes from Hokkaido, the output during recent years having been 4990 lb. in 1917, 5836 lb. in 1918, 1400 lb. in 1919, 5965 lb. in 1920, and 13.221 lb. in 1921. The domestic consumption, however, greatly exceeds the production and imports have risen from 344.010 lb. in 1913, to 402,240 lb. in 1921, and 420,708 lb. in 1922. After the war, however, importation was excessive, and in 1920 over 200,000 lb. was re-exported, principally to the United States, to relieve the local market. The local demand for mercury actually varies from 375,000 to 450,000 lb. annually. It is used in mining, in making minerals, thermometers, drugs, and vermilion for lacquer work. At present Great Britain supplies about

34 per cent. of the imports, China 24 per cent., United States 19 per cent., Germany 11 per cent., and Italy 8 per cent. Prior to the war, Germany, Italy and Austria-Hungary were the chief sources.—(*U.S. Comm. Rep., May* 21, 1923.)

FRANCE

National Fuel

Tests on touring cars and heavy vehicles have been carried out at Toulouse with the "National Fuel," consisting of 50 per cent. of petrol and 50 per cent. of ethyl alcohol, according to the Sabatier formula. Other vehicles using portable gas generators, heavy oils and vegetable oils took part in the test. The tests were designed to show the effect of the carburants on the pistons, valves and other wearing parts.

GENERAL

Quicksilver in 1921

According to reports prepared by the U.S. Geological Survey the output of quicksilver in the United States in 1921 was 6339 flasks (of 75 lb. each), valued at $300,595, compared with 13,392 flasks in 1920 and 21,415 flasks in 1919. The output in 1921 is the smallest on record, and the United States, the leading producer of mercury in 1917 and 1918, now stands a poor third. Apparently only two mines in the United States had ore of sufficiently high grade and were favourably enough situated to be able to operate at full capacity during 1921. The small domestic output in 1921 was not due to large imports as the total import was only 10,601 flasks, much less than in 1920, and about the same quantity as in 1919. Similarly, domestic consumption has fallen from 36,564 flasks in 1918 to 16,547 flasks in the year under review. Figures are given below showing the world's production of quicksilver from 1918 to 1921 in flasks (of 75 lb.) :—

	1918	1919	1920	1921
United States ..	32,883	21,415	13,392	4,754
Spain	16,677	36,055	25,330	13,244
Italy	30,512	24,839	41,182	24,244
Austria	12,346	—	—	—
Hungary	2,352	—	—	—
Czechoslovakia ..	—	2,352	2,352	2,204
Mexico	4,809	3,496	2,269	2,204
Other countries ..	1,000	1,000	1,500	—
	100,579	89,157	86,025	46,650

The monograph on mercury ores by E. Halse, published by the Mineral Resources Committee of the Imperial Institute (pp. 101, price 5s.), gives a general account of the occurrences, characters and uses of these ores. Amongst the uses, it is stated that, according to a recent British patent, the addition of small quantities of mercury increases the hardness of certain lead alloys, and in a recent German patent mercury is substituted for tin in making stereo- and type-metal alloys. The figures of production in 1921 given in the above table are quoted from this monograph. Of the sources of supply of mercury ores, the only areas in the British Empire where there is apparently any prospect of commercial extraction are British Borneo, Canada (British Columbia and Ontario), Australia (New South Wales, Queensland), Papua, and especially in the Puhipuhi district of New Zealand, where roughly 1,000,000 tons of ore, without overburden, is believed to exist. The deposits in Europe are too well-known to require mention, and it is stated that there are promising deposits in Algeria, Mexico, Chile and Peru. The world's production of mercury at present is reported to be about two-thirds of the normal pre-war amount and consumption is even lower owing to the general commercial depression and the small demand from Germany, formerly a large consumer. A useful feature of the report is a discussion on the metallurgy of mercury, in which it is stated that the average total cost of producing a flask of mercury in Europe is about 175s. at the present time. The monograph concludes with a useful bibliography.

Journal of Scientific Instruments

The preliminary arrangements for the regular publication of the *Journal of Scientific Instruments* have now been made by the Institute of Physics in co-operation with the National Physical Laboratory. The special attention of those workers who have new designs for instruments is called to the fact that the Journal is to serve as a medium for the publication of detailed descriptions and critical surveys of the behaviour of such instruments. Original papers or laboratory and workshop notes on the practical or theoretical aspects of scientific instruments should be sent to the Editor, Dr. J. S. Anderson, National Physical Laboratory, Teddington, Middlesex.

Bulgarian Salt Production

H.M. Commercial Secretary, Sofia, states that the production of salt in Bulgaria during 1922 amounted to 20,000 ton, 15,000 t. being derived from the Atanas Kiew district, near Bourgas, which is again being exploited. The amount produced last year was sufficient for home requirements, and the price was low.—(Official.)

Cement Production in the Far East

Cement manufactured in several districts in China is exported, but at present the imports, principally from Japan, are much larger than the exports, although China has an enormous wealth of cement-making materials, the three elements—clay, limestone and coal—being found together in many districts. The bulk of the Chinese exports of cement goes to the Philippines and smaller amounts to the Dutch East Indies and to Hong Kong. Shipments from a factory in Manchuria go to Korea and Siberia and are growing in importance. In Japan the production has increased from 1,800,000 barrels in 1908 to 6,500,000 barrels valued at over 6½ million yen (2s. 0½d.) in 1919. Cement is also produced in French Indo-China and in the Philippines.—(*Cham. Comm. J., June* 1, 1923.)

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for June* 14)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Galvanised tubular poles, steel girders (tender)	11450/E.D./E.C./2
,,	Plant for making pharmaceutical preparations	11446/E.D./CC.2
Belgium ..	Chemicals, pharmaceutical products	758
British India	Electrical plant, wires and cables	747
,,	Cresol (tender) ..	*
Canada ..	Marine paint	748
Denmark ..	Chemicals, colours, iron and steel	760
Dominican Republic	Roofing iron	782
Egypt ..	Building materials ..	772
Netherlands. .	Glass, earthenware ..	763
,, ..	Technical and surgical rubber goods	764
New Zealand	Tanning materials, paint and varnish	752
Nicaragua ..	Leather, paper ..	8157/F.L./M.C./2
Norway ..	Sugar	765
Panama ..	Leather	783
Portugal ..	Tinplate, zinc sheets..	766
South Africa	Paint and varnish ..	756
,,	Stoneware pipes (tender)	11466/E.D./M.C./2
United States	Asbestos lumber ..	775
,,	Shellac, varnish gums	776

* The Director-General, India Store Department, Branch No. 10, Belvedere Road, S.E. 1.

TARIFF CUSTOMS EXCISE

Belgium.—Increased duties have been levied on the following articles (for which certificates of origin are required) :—Iron and steel, copper, paper, hides and skins, tin, lead and glassware.

Canada.—The rates of duty on iron and steel, dry red lead, orange mineral and zinc white, crude petroleum and artificial silk, have been revised.

Greece.—The duties on superphosphates, patent medicines, glassware, copper tubes, zinc, and inner tubes, have been modified. The importation of copper sulphate and of sulphur has been prohibited.

Honduras.—Cement, iron and steel girders, galvanised iron, and zinc plates are admitted duty free.

New Zealand.—Rubber goods will no longer be subject to depreciated currency surtax.

Poland.—The importation of sugar has been permitted.

Spain.—A Royal Order has been issued regulating the importation of solid rubber tyres, covers and tubes.

Syria.—Permission has been granted for the export and re-export of lead, slates and other building materials.

Syria and Lebanon.—The following goods are subject to sanitary inspection :—Olive and white oils, edible fats, sugar, saffron, vanilla, paper, coal tar, paint, soap, mineral oils, rubber, petroleum, chloride of lime, leather, natural fertilisers and a variety of heavy and fine chemicals.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

British Dyestuffs Corporation (Wages)

Sir W. Joynson-Hicks, replying to Mr. W. M. Adamson, said that the reduction made by the British Dyestuffs Corporation of a further ½d. per hour in wages in two cuts upon their employees, applied generally to the trade. He saw no reason for instituting an inquiry regarding its application to a single undertaking.—(June 18.)

Opium Traffic

Mr. Bridgeman informed Sir W. de Frece that at the meeting of the Advisory Committee on the Opium Traffic at Geneva it was decided to recommend the adoption by the interested Powers of measures for the more effective application of Part 2 of the International Convention of 1912 relating, *inter alia,* to the limitation of the manufacture of morphine, heroin and cocaine, and the production of the raw material from which these drugs were made.—(June 12.)

Manufacture of Dangerous Drugs

Replying to Captain Hay, Mr. Bridgeman said that at present two factories were licensed for the manufacture of morphine and heroin. In 1922 the amount of morphine made was 315,342 oz., of which 173,010 oz. was converted into codeine or heroin. The export was 115,465 oz. In the same year 31,673 oz. of heroin was manufactured and 25,911 oz. exported.—(June 13.)

The Albert Medal of the Royal Society of Arts has been awarded in duplicate to Major General Sir David Bruce, K.B.E., F.R.S., and Colonel Sir Ronald Ross, K.C.B., F.R.S., in recognition of their eminent services in the study of tropical diseases.

COMPANY NEWS

BRUNNER, MOND & CO., LTD.

Presiding over the ordinary general meeting, held in Liverpool on May 25, Mr. Roscoe Brunner said that the past year was better than the previous one. It was proposed to divide 75 per cent. of the trading profits, carrying the remainder to reserve, which now totalled nearly £3,300,000. The wages of shiftmen were 121 per cent. and of day-men, other than mechanics, 104 per cent. over the pre-war level. Work on the ammonia-soda factory at Wallerscote was proceeding as fast as possible, and progress was being made with the Billingham works of Synthetic Ammonia and Nitrates, Ltd.

The balance at credit of profit and loss was £1,650,295, which with £9293 brought forward, made a total of £1,740,588. Preference dividends of 7½ per cent. and ordinary dividends of 11 per cent. have been paid, absorbing £300,000 and £1,061,461 respectively; £62,215 was carried to reserve, making a total of £900,000, and £225,000 to suspense account, leaving £91,000 to be carried forward. It was resolved to issue up to 100,000 ordinary shares to the staff and work people.

THE BRITISH COTTON AND WOOL-DYERS' ASSOCIATION

The annual meeting was held in Manchester on May 16. In his address the chairman, Dr. A. Hoegger, said that as long as costs of labour and coal were double, and chemicals and dyes ten times the pre-war amount, dyers and bleachers could do little to reduce prices. The pledge that the textile and other colour-using industries should not be placed in an unduly disadvantageous competitive position by the Dyestuffs Import Regulation Act had not been kept, and British colour-users had to pay far higher prices for dyestuffs than those charged to competitors abroad. The Licensing Committee had agreed to grant import licences when British dyestuffs cost more than three times the pre-war value, allowing for strength and quality, but this had not been carried out, and often unsatisfactory reasons for refusal were given. It was essential that the dyestuffs industry should be firmly established in this country, but it was not fair that it should be built up at the expense of colour-users. The Association agreed with the suggestion that a direct Government subsidy should be given to British dye-makers, and colour-users would probably be willing to contribute towards the amount required.

The net profit of the past year, including a carry-forward of £5250, was £199,476. Dividends were paid of 10 per cent. on the ordinary shares plus a bonus of 5 per cent.; £50,000 was transferred to reserve fund, which now totals £225,000, and £42,382 was carried forward.

REVIEWS

LEHRBUCH DER CHEMIE. *By* PROF. MAX TRAUTZ. *Vol. II. Pp. xxxiv*+634. *Berlin and Leipzig: Vereinigung Wissenschaftlicher Verleger*, 1922. *Price* 25*s*.

This volume is devoted almost exclusively to the physical side of chemistry. The first part deals with the gas laws, and contains a brief description of a few examples of analytical chemistry in which the estimations depend upon the volume measurement of various gases. The thermodynamics of isothermal and adiabatic changes is then dealt with, and this is followed by an account of the behaviour of gases when strongly compressed, together with a critical discussion of Van der Waal's equation. The fundamental principles of the liquefaction of gases are described. The molecular structure of crystals and their optical properties are explained, and an excellent coloured plate showing the polarisation colours is given. Chapter II. deals with the properties of solutions non-electrolytic, electrolytic and colloidal; the effect on the surface energy; the optical and electrical properties of colloidal particles, together with a brief account of the methods of producing various colloidal solutions. The last portion of Part I. is devoted to a consideration of the kinetic theory of matter in the gaseous, liquid and solid states, a brief description of Laue's photograms and X-ray spectra being given in connexion with the theory of crystal structure. The physical properties (thermal and optical) of mixtures are considered.

The second part of the book is devoted to the dynamics of chemical actions. The second law of thermodynamics is discussed, and its application, as well as that of Le Chatelier's theorem and Clausius' equation to certain physico-chemical problems is explained. The equilibria diagrams of some single-component systems and diagrams showing the relationship between the water-content of gels and their vapour pressures are given, as is also an account of the thermodynamics of binary mixtures in relation to fractional distillation, lowering of vapour pressure, etc., of dilute solutions. The law of mass action as applied to many gaseous reactions of considerable technical importance is explained, and its application to solutions of electrolytes given. The Gibbs-Helmholtz equation and the Helmholtz-Thomson rule regarding the connexion between electrical and chemical energy are dealt with. The temperature co-efficient of the equilibrium constant is considered in the part dealing with Van't Hoff's equation to the reaction isochor. Gibbs' phase rule is applied to heterogeneous systems in equilibrium. Single potential differences, the E.M.F. of cells, and the electrochemistry of oxidation and reduction processes are discussed. An explanation of the numerous cases that can arise in the diagrams showing the equilibria between the various phases in a two-component system is given and three-component systems are briefly dealt with. The application of the foregoing to the formation of a number of minerals and alloys is an important part of this chapter which also contains a table showing which metals form the more important alloys and a fairly comprehensive survey of the mineral silicates. The last part of the book is devoted to a consideration of Nernst's heat theorem and the laws of radiation. The absorption spectra of the rare earths are described, and the position of these substances in the periodic classification of the elements is discussed. The natural radiation frequency, Planck's quantum theory and their application by Einstein, Nernst and others, to the calculation of the specific heats of crystalline solids, and the dissociation of some diatomic gases, etc., are dealt with.

The work as a whole is most comprehensive and covers a very wide field as may be judged from the fact that the table of contents at the beginning of the book occupies twenty-eight closely printed pages, and the index at the end consists of twenty-eight pages of three columns each. These, together with the marginal notes, make the book exceptionally well-indexed. There are, however, two or three peculiarities from which the work suffers. Many of the diagrams are far too small. Only in a comparatively few cases are actual examples quoted in order to illustrate a law or theorem that has been discussed. With the exception of two or three papers quoted in connexion with Nernst's heat theorem, no original references are given. In so large a work as this, more especially as it is intended for private study and the use of teachers, one would naturally expect references to original papers of fundamental importance to be quoted. After each subject has been discussed a summary of the results, definitions and laws is given: this, although quite useful, seems to be overdone. In parts the work is of necessity mathematical, and, obviously with the object of enabling the reader to follow the treatment given, a few pages are interspersed here and there which are devoted to a description of the mathematical formulæ used and an explanation of the operations involved. This seems unnecessary, as alone they can scarcely be regarded as proofs, and are insufficient to enable a reader with no knowledge of higher mathematics to grasp the meaning of the problems dealt with, whereas one possessing such knowledge as to be able to understand all the operations involved will have no difficulty in finding anything that may be required in a text-book of mathematics. In this volume advanced students and teachers of chemistry will find much of interest and value in the more theoretical treatment of the fundamental laws underlying chemical action.

A. Bramley

Laboratory Manual of Physical Chemistry. *By* Albert W. Davison *and* Henry S. van Klooster. *Pp. viii. + 182. New York: John Wiley and Sons; London: Chapman and Hall,* 1922. *Price* 10*s.*

This book consists of a collection of twenty-four exercises designed for the use of large classes of students who are simultaneously being given a course of theoretical instruction, and is especially addressed to students of engineering. Detailed instructions are given for the recording of results; the book is interleaved with blank pages and contains also some excellent graph paper. In these respects it differs from the more usual type of text-book on this subject, as also in the fact that the outlines of theory required for intelligent working and the interpretation of results are intended to be obtained from lists of references to specified chapters of selected text-books. In the reviewer's opinion it would have been better to follow the usual practice and make the book self-contained in this respect, especially as the relatively small amount of additional matter could easily have been printed in some of the very liberal space alloted to these lists. Whilst the selection of exercises is on the whole a wise one, there are others which seem to have a strong claim for inclusion. Amongst the omissions are:—the measurement of viscosity, the solubilities of gases and of solids in liquids, and spectroscopy. Much space is rightly devoted to the distillation of binary mixtures, and here the bibliography would have been strengthened by reference to Young's *Stoichiometry* and *Distillation Principles and Processes.* Among the newer features of the book are descriptions of a form of breaking release in the Victor Meyer vapour-density apparatus, the compact Eykman apparatus for determining molecular weight by elevation of boiling point, the phase diagram of the system Cd. Bi, and the choice of a bimolecular reaction.

In determining distribution ratio it is desirable to use some kind of rough thermostat; also it is neither necessary nor advisable to raise to the boil solutions containing benzoic acid, except perhaps at the end of a titration.

In the electro-chemical part there are no exercises on Faraday's laws except incidentally in the exercise on transport number. The hydrogen electrode is only used for electrometric titrations, and there are important omissions in the usually very detailed instructions, since no reference is made to the necessity for allowing the potentiometer current to become teady and for saturating the hydrogen electrode.

The suitability of the book for classes of university and technical college students in this country will probably be decided on some of the grounds mentioned above.

The book is well bound and printed; it has large and clear diagrams and will no doubt be a useful addition to the modes of presentation of this subject.

E. B. R. Prideaux

DIE INDUSTRIELLE HEIZUNG: ZUR EINFÜHRUNG IN DAS STUDIUM DER METALLURGIE. *By* H. LE CHATELIER. *Authorised German translation of the second French edition by Dr. B. Finkelstein. Pp. viii+418. Leipzig: Akademische Verlagsgesellschaft m.b.H.,*1922. *Price* 13*s.*

In this work we find industrial heating considered as an integral portion of the study of metallurgy. The subject matter is wide in scope and originally formed the course of lectures in the Ecole des Mines. Owing to limitation of space, as well as to its origin, the volume cannot be said to deal with the subject as comprehensively as might be desired. Indeed, in the reviewer's opinion, the treatise appears mainly to fulfil the function of an excellent text-book, the purpose of which is to lay the foundation of a general scientific knowledge of the subject of fuel. An investigator, however, interested in any particular aspect of the industrial heating problem, is hardly likely to gain from its perusal anything further than the fundamentals governing the application of the knowledge of which he is in search.

An intensely interesting introductory chapter deals with the relations and points of difference between science and technology, which should be of great value in the formation of that wider outlook so necessary to the student who proposes to put to practical use the knowledge acquired in the university or technical college.

The first chapter takes for its subject the general question of fuels and the chemistry and physics of combustion, whilst subsequent chapters consider in the logical manner associated with the author's name such matters as economy in heating, natural fuels, carbonisation, acetylene and water gas, illuminating gas, refractory materials and ovens, furnaces and kilns.

Carbonisation is dealt with from the standpoint of the existing industries, such as the manufacture of wood, charcoal and gas, and the production of metallurgical coke. Some stress is laid upon the desirability of regeneration, but here again limitation of space has apparently forced the author to confine himself to generalities. Certain important subjects at present engaging the attention of the carbonisation industries are conspicuous by their absence, these including the wide range of research work at present being undertaken in this country by the gas undertakings as a result of the freedom of working granted to them by the Gas Regulation Act of 1920. Nor is mention made of the possibilities of low-temperature carbonisation of coal in spite of the fact that data to a considerable extent are available, and inquiries in this direction are being prosecuted in French mining circles.

The difficult question as to whether the distillation of coal is or is not an exothermic process is treated in a paragraph of some two hundred words, the author having quoted briefly from the work of Mahler. Although at first sight the subject may appear relatively unimportant, dealing as it does with quantities of heat in the neighbourhood of 1 or 2 per cent. of the initial heat content of the coal, it assumes greater importance in connexion with those methods of carbonisation depending upon internal heating by the sensible heat of gases. The quality and quantity of the final mixture of distillation and heating gases depend upon the quantity of heating gas used; and it is quite conceivable that a process which might be of commercial value when the distillation acts upon the whole in an exothermal direction, would produce an unmarketable gas should thermal conditions operate in the opposite direction. In spite of the scant attention which has been given to this aspect of the subject, the author is to be congratulated on having avoided quotation of the doubtful conclusions which have been put forward from time to time in various quarters.

In a few paragraphs M. le Chatelier deals with peat as a raw material either for domestic use or in connexion with carbonisation, but dismisses in a word or two the large amount of experimental work which has been done in this field during the past few years in Canada, Germany and Scandinavia. No reference is made to the marked effect upon both the drying and the hardness of the resultant fuel by a simple process of maceration before spreading and air drying. During the course of some experimental work in Ireland three crops were obtained by means of this process during an exceptionally wet season, as compared with the one crop of air-dried peat usually obtained by hand-cutting. The method indicated also results in the production of a very dense fuel of specific gravity in the neighbourhood of unity. Such blocks can be sawn and can easily withstand the disintegrating effects of transport.

The volume under consideration appears to offer a fairly close translation of the original work, but the general production and paper are decidedly poor. It is recognised, however, that M. le Chatelier's work should be of considerable value for teaching purposes in Germany, since the author has from first to last realised the necessity of treating the subject in a thoroughly scientific manner, presenting the fundamental facts. Its study should render the student capable of drawing accurate conclusions when dealing with the practical applications encountered in the metallurgical industries, but there are already books in English catering for his needs in this direction.

C. H. L.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Although business is still very much on the quiet side when looked at from the standpoint of tonnage, there is a decidedly better tone prevailing in the chemical market. The Continental position again renders buyers somewhat nervous, but prices are steady, and forward purchasing almost entirely absent. Undoubtedly the strongest feature is the continued steady business in alkali and caustic soda, which show distinct firmness.

Acetic Acid, 40% tech.	£24 per ton. Still firm, but rather less inquiry.
Acid Hydrochloric	3s. 9d.-5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw.	£24 10s. per ton. Quiet.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Demand steady, export inquiry good.
Arsenic (White)	£71-£74 per ton. No increase in business.
Bleaching Powder	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Business much below normal.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand.
Copper Sulphate	£27 per ton.
Potash Caustic	£33-£34 per ton. Little moving.
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Potass. Chlorate	3d. per lb. Very dull.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76%	£20-£21 per ton. Steady demand.
Soda Crystals	£5 5s.-£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£26 per ton. Very scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. More business lately.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	2¾d.-3¼d. per lb. Very dull.
Sod. Nitrate refd. 96%	£13 5s.-£13 10s. per ton ex Liverpool.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	£15-£16 per ton carr. paid. Very quiet. Prices unstable.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. por lb.
Carbon Bisulphide	£26-£28 per ton according to quantity.
Carbon Black	1s. 5½d. per lb. ex wharf. Still very scarce.
Chromium Oxide	1s. 5d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb. Firmer on advance in price of Rape Seed Oil.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£11 10s. per ton.
Thiocarbanilide	2s. 6d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood distillation products.

Acetate of Lime—	
Brown	£10 15s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 10s. per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£6 per ton d/d.
Brown Sugar of Lead	£45 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 4½d.-1s. 5d. per lb. A better demand at these prices.
Crude 60's	3s. 4d.-3s. 6d. per gall. Not much business.
Acid Cresylic—97/99	2s. 0d.-2s. 6d. per gall. Demand fairly good.
Pale 95%	1s. 10d.-2s. 5d. per gall.
Dark	1s. 10d.-2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	8¾d.-11d. per gall. Not much demand.
Unstrained	8¼d.-9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1¼d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.

Benzole (*cont.*)—	
Pure	2s.-2s. 2d. per gall. No business.
Toluole—90%	1s. 9d.-2s. per gall. Quiet.
Pure	2s.-2s. 6d. per gall. Not much inquiry.
Xylol	3s.-4s. per gall. according to quality. Good demand.
Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil Heavy Standard Specification	8d.-9¾d. per gall. Market steady. Good demand.
Naphtha—	
Crude	8½d.-10½d. per gall.
Solvent 90/190	1s. 7d. per gall. Market quiet.
Solvent 90/190	1s. 5d.-1s. 7½d. per gall. Market moderately active.
Naphthalene Crude—	
Drained Creosote Salts	£6-£8 per ton. Fair demand. Supply short.
Whizzed or hot pressed	£11-£14 per ton. Plenty of inquiries.
Naphthalene—	
Crystals	£18 per ton.
Flaked	£16 10s. per ton.
Pitch, medium soft	No business for this season. Prices for Autumn delivery 125s.-127s. 6d. per ton, f.a.s. Manchester.
Pyridine—90/140	16s.-18s. per gall. Dearer. Demand still good.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Since the beginning of June there has been a decided improvement in business in aniline dyestuffs. There is considerably more inquiry about and orders have improved both in number and weight. There is every likelihood of still further improvement in the near future.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 8d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 9d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market has been quiet, and prices weaker in consequence of lack of business.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s.-3s. 3d. per lb. The tendency is to ease somewhat, but the strong demand prevents any marked lowering of prices.
Acid, Benzoic	2s.-2s. 9d. per lb. Still very scarce.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8¾d. per lb., less 5%.
Acid, Gallic	3s. per lb. Steady demand.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d. per lb. for quantity.
Acid, Tannic	3s. 6d. per lb. Firmer tendency.
Acid, Tartaric	1s. 4d. per lb. Demand still below normal owing to bad season.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d. per lb. Slow of sale.
Amidopyrin	14s. per lb. Still neglected.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. per oz.
Barbitone	22s. per lb. In very short supply.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Owing to the fluctuation in marks, Hamburg dealers are offering all bromides on this market at very low rates, but British makers maintain their prices without difficulty.
Calcium Lactate	2s. 9d. per lb. for best makes.
Chloral Hydrate	4s. per lb., duty paid.
Chloroform	2s. 2d. per lb. for cwt. lots.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	£90-£92 per ton. Very firm.

Guiacol Carbonate	8s. 6d. per lb.
Hexamine	4s. per lb. down to 3s. 10d. for ½ ton lots. Tendency rather weaker.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Market good with considerable inquiry.
Magnesium Carbonate—	
Light Commercial	£37-£38 per ton net, according to quantity.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	1s. 9d.-2s. per lb. Good demand.
Menthol	40s. per lb. spot.
Methyl Salicylate	2s. 6d. per lb. for carboys. Somewhat weaker in common with other salicylates.
Methyl Sulphonal	15s. per lb.
Paraformaldehyde	3s. 6d. per lb. Weak.
Paraldehyde	1s. 6d. per lb. accepted for large orders. In better supply.
Phenacetin	6s. 6d. per lb. spot value. Very steady.
Phenazone	7s. 6d. per lb. Very firm.
Phenolphthalein	7s. per lb. now wanted by most holders. Considerable advance in view of shortage.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	96s.-98s. per cwt., less 2½%.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. In very strong demand, with no offers from Japan, where there seems to be a great shortage.
Potass. Permanganate	10d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	6s. per lb. still quoted without inquiry.
Salol	2s. 9d. per lb.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 9d. per lb. now wanted by holders. Still in short supply, fresh stocks being quickly absorbed.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality.
Sod. Hyposulphite—	
Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	80s.-82s. per cwt. net.
Sod. Salicylate	Demand not so good. Powder is slightly weaker at 2s. 7d. per lb., with crystal at 2s. 9d. per lb.
Sod. Sulphite, anhydrous	£27 10s.-£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.
Thymol	16s. per lb. would now buy finest white crystals. Demand very slow.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Butyrate	7s. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	4s. 3d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	2s. 9d. per lb.
Benzyl Benzoate	3s. 3d. ,, ,,
Cinnamic Aldehyde	17s. 6d. ,, ,,
Coumarin	18s. 6d. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	18s. 6d. ,, ,,
Ethyl Phthalate	4s. 3d. ,, ,,
Eugenol	11s. 6d. ,, ,,
Geraniol (Palmarosa)	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	16s. 6d. per lb.
Linalol ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	21s. ,, ,,
Methyl Anthranilate	7s. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Xylol	11s. ,, ,, Dearer.
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	23s. 6d. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	2s. ,, ,,
Bergamot Oil	12s. 6d. ,, ,, spot.
Bourbon Geranium Oil	29s. ,, ,,
Cananga Oil, Java	9s. ,, ,,
Cinnamon Oil, Leaf	4¼d. per oz.
Cassia Oil 80/85%	12s. 6d. per lb. Sharp advance.
Citronella Oil—	
Java 85/90%	4s. 2d. ,, ,,
Ceylon	3s. 8d. ,, ,, Dearer.
Clove Oil	8s. per lb.
Eucalyptus Oil 70/75%	1s. 10d. per lb. Dearer.
Lavender Oil, Mont Blanc 38/40%	13s. ,, ,,
Lemon Oil	3s. 1d. ,, ,,
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	13s. 7d. per lb. Advanced.
Otto of Rose Oil—	
Anatolian	24s. per oz.
Bulgarian	30s. per oz.
Palma Rosa Oil	19s. per lb.
Peppermint Oil—	
English	80s. ,, ,,
Wayne County	13s. ,, ,,
Japanese	6s. 7½d. ,, ,, Advanced.

TRADE NOTES

Germany's Export Trade in Chemicals

Estimates prepared by the "Verein zur Wahrung der Interessen der Chemischen Industrie Deutschlands" state that the exports of German chemicals (excluding deliveries on reparations account) in 1922 were 890,000 metric tons valued at 290,000,000 gold marks, compared with 690,000 t. (330,000,000 gold marks) in 1921, and 2,529,000 t. (912,000,000 gold marks) in 1913. The chemical industry imports about 1·8 per cent. of the total German imports, whereas the textile industry imports about 12·8 per cent., so that the chemical industry, with most of its raw material produced at home, has, perhaps, prior claim to importance as an asset in Germany's foreign trade, of which it represented 7·8 per cent. in 1922.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the above Act during May, 1923, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee:—

The total number of applications received during the month was 497, of which 409 were from merchants and dealers. To these should be added the 17 cases outstanding on May 1, making a total for the month of 514. These were dealt with as follows:—

Granted, 304 (of which 293 were dealt with within seven days of receipt).

Referred to British makers of similar products, 136 (of which 130 were dealt with within seven days of receipt).

Referred to Reparation Supplies available, 53 (all dealt with within two days of receipt).

Outstanding on May 31, 21.

Of the total number, 514, of applications received, 458, or 89 per cent., were dealt with within four days of receipt.

PUBLICATIONS RECEIVED

Chemistry Inorganic and Organic, with Experiments. *By* C. L. Bloxam. *Eleventh edition, revised by* A. G. Bloxam *and* S. Judd Lewis, D.Sc. *Pp. ix+832. London: J. and A. Churchill*, 1923. *Price* 36*s*.

Alcoholic Fermentation. *By* A. Harden, Ph.D., D.Sc., F.R.S. *Third Edition. Pp.* 194. *London: Longmans, Green and Co.*, 1923. *Price* 6*s*. 6*d*.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JUNE 29, 1923 No. 26

EDITORIAL

THE *Morning Post*, two or three days ago, published a further instalment of the Farington Diary for the year 1810, from which we make the following extract.

"March 7th.—Smirke's I dined at.—Lysons spoke of the death of the Honble. Henry Cavendish, F.R.S. He was the largest Stockholder in England. He had in different stock to the amount of a million Sterling. He had also a large landed estate. He left of His stock two 6ths. to His Cousin Lord George Cavendish; & to each of three of His Sons, one sixth each, & the remaining Sixth to His Cousin Lord Besborough.—He also left £15000 to Sir Charles Blagden; He was son to Lord Charles Cavendish, Great Great Uncle to the present [the fifth] Duke of Devonshire. He had been a constant attendant at the Royal Society Club for 50 years past, at the Crown & Anchor tavern, a dinner meeting every Thursday throughout the year. He resided principally at Clapham. He was a man of mild manners, but it was remarked of Him that He was in His political sentiments always in opposition to whoever might be in power. His Philosophical discoveries had long made Him a distinguished man. He was born Octr. 30th, 1731, & died Feby. 24th, 1810."

In a leading article of the same issue the *Morning Post* takes as its text, Farington's phrase, "He was a man of mild manners, but it was remarked of him that he was, in his political sentiments, always in opposition to whoever might be in power." In a light vein of philosophy our contemporary makes a number of reflections on people who rebel against authority, not all of whom are distinguished by the mildness of their manners. To chemists the extract is of some interest, for the date of Cavendish's death has been hitherto somewhat disputed.

* * *

We sometimes wonder whether the Society takes due advantage of its opportunities for publicity. Take for instance, the Presidential address: this is usually delivered in the middle of the morning after a Council meeting and a business meeting when important matters have been discussed. No matter how good the address may be, how many points are made in it, what questions of policy are involved, time does not permit any adequate discussion of it. This year the address is one which requires a good deal of careful study, and if such topics as the education of chemists, their status and function in society, the co-operation of chemical societies, the Federal Council Fund and journalistic experiments, cannot be discussed immediately after the delivery of the address, it might nevertheless be very useful to have them discussed at some other time during the meeting. The members of Council have a few opportunities of discussing these matters, but the great majority of the members have practically no such opportunities. A rather informal debate on some such matters might elicit interesting points of view, and disclose powers of oratory which hitherto have blushed unseen. The daily newspapers can hardly be expected to publish leading articles on tautomerism or colloid chemistry, but they could very conveniently deal with some of the larger questions such as have been indicated, and in this way their readers might gradually realise that many chemists exist besides those who sell tooth-brushes and weed-killer. It occurs to us that at some Annual Meeting a special effort might be made to stir up activity in such directions. The President has indeed indicated some directions in which this may be done, and his remarks show that he has some fairly definite views on a number of these which in due time he will disclose. It is a pity that when our interest and enthusiasm are aroused we cannot speedily measure the extent to which they will evoke active help from so large and influential a body as the members of the Society assembled in General Meeting. Probably late in the autumn there will be the usual dinner of the Society in

London; can this occasion be made use of for some real discussion, not a few after-dinner speeches by carefully selected raconteurs, but an open talk for two or three hours, where everyone can criticise, make suggestions, offer to help and light such a fire as no man shall ever put out? Then afterwards let us refresh our bodies with meat and drink, and unbend our minds with the aid of flippant jests and carefully thought out repartee. This year will be an important one in the development of ideas, and we hope at Liverpool it will be found possible to spare a large measure of time for their consideration.

* * *

We awaited with great interest the announcement of the results of the Ballot for Members of Council, but we were extremely disappointed to learn that only about eight per cent. of the total membership of the Society had sent in voting papers. For some time past the President has not spared himself in urging chemists to work for the unity of their profession, and, considering the new spirit that prevails in chemical circles, we were surprised that so few members had fulfilled one of their corporate obligations. This apathy is, unfortunately, characteristic of the age; in parliamentary and municipal elections the proportion of the electorate that goes to the polls is far too small, and in certain foreign countries it has been found necessary to pass legislation compelling citizens to use their votes. The results of this neglect are too obvious to need comment, and it is our concern only to record the fact. It has been suggested that as our membership is so widely scattered, members may not be sufficiently "in touch" to feel justified in discriminating between the names set down on the ballot paper. But it can be urged that votes are often given for parliamentary or municipal candidates of whom little is known save their political "label," and, in any case, it is always possible to obtain unbiased information. The question is too important to be neglected, and we invite members to send us their views, so that discussion may suggest a remedy.

* * *

The Society of Chemical Industry has made a new departure in electing honorary members. Five men of distinction in chemistry have been elected as such—Dr. C. F. Chandler, an American who was President of the Society in 1899-1900; Monsieur Paul Kestner, the President of the Société de Chimie Industrielle; Prince Ginori Conti, President of the Italian Chemical Society, who has harnessed for power purposes the steam issuing from the earth in some volcanic districts of Tuscany; Prof. H. Sakurai, one of the best known of Japanese chemists; and Sir Dorabji Tata, a founder of great chemical and engineering works in India, and one who has generously endowed science in that country.

BYGONE CHEMICAL TECHNOLOGY

By Prof. J. R. PARTINGTON, M.B.E., D.Sc.

In a recent book* Prof. Fester has attempted an account of the development of chemical technology from the earliest times to the beginning of the nineteenth century. His sources have been mainly existing treatises on the history of chemistry and the introductions to technical works, although he has apparently made use of some original treatises, the number of which was especially large about the period of the amazingly productive sixteenth century. In the following sketch many statements are not found in the book in question, the author of which must not be held responsible for them. The illustrations have all been added by the reviewer.

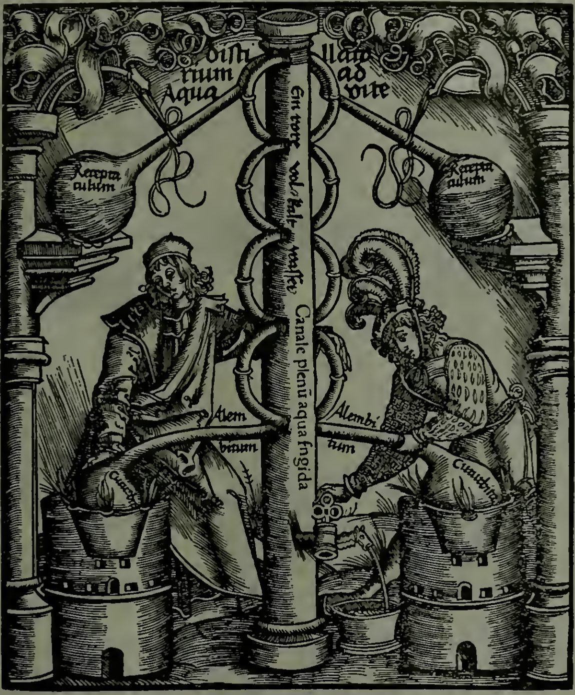
One of the oldest branches of chemical technology is the art of working in metals. Gold objects of the Neolithic Period (*c.* 10,000 B.C.) have been found, and gold ornaments occur in the oldest tombs of Egypt (*c.* 5000-3500 B.C.). Copper appears in Egypt, but sparingly, as early as 4000 B.C.; by 3000 B.C. it had displaced stone implements, and it is noteworthy that the earliest copper contained arsenic, which made it harder and more fusible. Bronze appeared first about 3000 B.C., both in Egypt and Mesopotamia; in Babylonia the tin was partly replaced by lead. In Central Europe the alloy did not appear until about 2000 B.C., and the earliest articles of bronze were probably imported. Egypt imported tin for bronze-making from the East, probably from Persia. The Scilly Isles, which served as a market for British tin, appeared as part of the Phœnician trade route not before 1000 B.C. The "Cassiterides," doubtless the British Isles, appear as sources of tin first in Herodotus, about 550 B.C. The Ægean civilisation centred about Crete was the forerunner of the Phœnician in maritime trade; Ægean traders penetrated to Egypt, and an interchange of Egyptian and Ægean wares occurred as early as 1400 B.C. After the sack of Knossos, the Minoan civilisation relapsed, and the Phœnicians appeared. The oldest iron seems to be the fragment found in the pyramid of Cheops (IVth Dynasty), but iron was scarce in Egypt until 1200 B.C. Silver appears in the Ægean about 2900 B.C.; Mesopotamia in the time of Hammurabi (*c.* 2000 B.C.) was rich in silver, the shekel being the unit of coinage. In Egypt silver was more valuable than gold as late as 1500 B.C.; it came from the North through the Phœnicians, perhaps from Spain, which was no doubt the source of the mercury found in an Egyptian tomb of the fifteenth or sixteenth century B.C. Mercury is first definitely mentioned by Aristotle

---

* *Die Entwicklung der Chemischen Technik bis zu den Anfängen der Grossindustrie. Ein Technologisch-Historischer Versuch.* By Gustav Fester. Pp. viii+226. Berlin: Springer, 1923. Price: paper, 6s. 3d.; bound, 7s. 6d.

(384-322 B.C.). The famous "asem," probably a natural electrum or gold-silver alloy from Nubia, is mentioned in one of the oldest Egyptian inscriptions: it played an important part in the beginning of alchemy in the Alexandrian period, as is shown by the Leyden papyrus (*c.* A.D. 100).

Tanning was in use in Egypt under Sesostris (*c.* 1880 B.C.); dyed mummy wrappings appear as early as 2500 B.C., indigo being first used in Egypt about 1000 B.C., as is proved by recent discoveries. The "Phœnician purple" is now known to have been produced in Crete about 1600 B.C. The Egyptian blue, used as a glaze, and in powder form as a pigment, dates back to the earliest period; it was essentially a frit of copper, sand and natural soda, the preparation being described much later by Vitruvius. One dark blue glaze of 1375 B.C. is coloured almost entirely by cobalt.

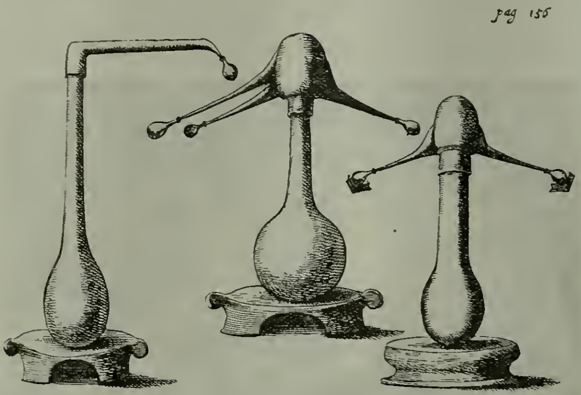


Fractionating Column for the Distillation of Alcohol in Ulstadius' "Coelum philosophorum," 1526

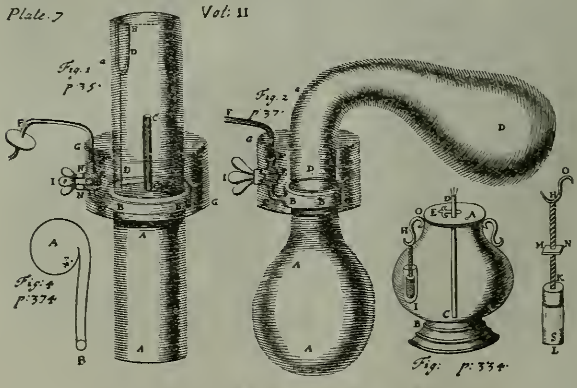
The manufacture of glass probably arose in Egypt, the soda being obtained from the lakes. Tyre and Sidon became only later centres of glass manufacture, but their fame lasted until the Middle Ages. Egyptian glass beads of 3500 B.C. are the earliest specimens; a lead glass vase of 2800 B.C. was merely fritted, and the first important centre of glassmaking appears to have been Tell-el-Amarna (fifteenth century B.C.). The first glass vase dates from 1500 B.C., although glass work, including imitation gems, was much older, as stated above. The glass was moulded; glassblowing was probably invented in Sidon only about the beginning of the Christian era.

In his description of the Hellenistic period Prof. Fester probably lays too much stress on the supposed close connexion between the development of chemistry and the Egyptian priests. The descriptions of Otto, on which Lippmann, for instance, appears to rely, speak rather against than for any personal activity of the priests in technical matters, and in any case Otto disclaims any special knowledge of Egyptology. Workmen were attached to the temples to do various kinds of work, but they were not priests, and their work was of no unusual character.

It is quite possible that the "divine art" (θεία τέχνη) may have been only the "sulphurous art" of producing changes in metals by *sulphur* (θεῖον), including arsenic. The papyri of Leyden and Stockholm can hardly bear the interpretation of being intimately connected with temple industries: they are almost certainly the working-notes of a successful and fraudulent Egyptian goldsmith; they were buried in his tomb so that, in accordance with religious beliefs, he would have them available for use in the next world. The expression: *ώς καὶ τοὺς τεχνίτας λανθάνειν*, quoted by Fester, speaks for this: “as good as, if not better than . . .” is in common use to-day in similar circles! Alexandria, in the Hellenistic and Roman periods, was a buzzing hive of industry, as is testified by Hadrian's well-known letter (now regarded as apocryphal). The glass industry was particularly famous. For this period we have the inimitable *Historia Naturalis* of Pliny, which was drawn upon by later authors—even by Agricola in the sixteenth century. The preparation of white lead by the “Dutch process” is mentioned, but precise directions for its preparation in this way date back to Theophrastos (fourth century B.C.). A Bactrian coin of the third century B.C. contains nickel: oxide of zinc was known to Dioscorides (A.D. 75) as a deposit in brass furnaces; vitriols (blue and green) and alum, cinnabar, orpiment, etc., are all described by Pliny. “Nitrum” was probably natural soda, not saltpetre.



Distillation Apparatus of Zosimus (c. A.D. 300) reproduced by Olaus Borrichius, 1684

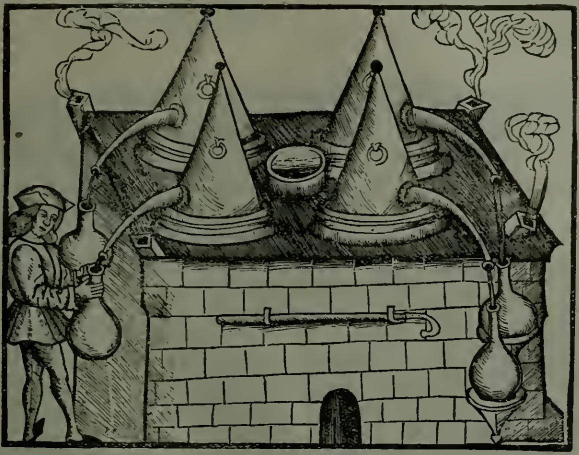


Robert Boyle: Apparatus for Distillation in Vacuum

It was in Hellenistic Egypt at the beginning of the Christian era that distillation was probably first invented. This was clearly stated by Hoefer (*Hist. de la chimie*, 1842, 1, 196). Pictures of distillation apparatus occur in the manuscript of Zosimus (fourth century A.D.), in the Paris National Library. This was seen by Borrichius, in whose book (*Hermetis Aegyptiorum et chemicorum sapientia*, Copenhagen, 1684) there is a reproduction of the alembics figured in Zosimus (ἄμβιξ, which the Arabs called *al-ambic*). These Greek MSS. are referred to by Agricola (*De re metallica*, 1556), but were first carefully examined by Hoefer at the beginning of the last century. The text and translation have been published in full by Berthelot.

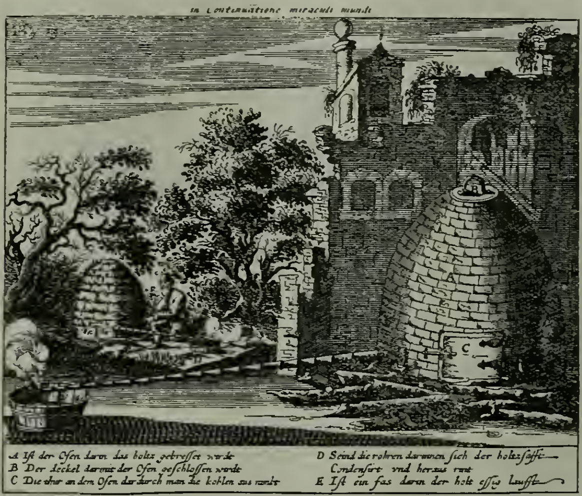
Fester suggests (p. 28) that the famous Roman *vasa murrhinae*, of which Nero was an ardent collector, were Millefiori glass (bundles of coloured fibres melted together: 1830 B.C.)—but Pliny says: "ob amorem abroso ejus margine" of a wealthy Roman owner—surely not of *glass*. We miss Pliny's account of malleable glass: the inventor showed a cup to Tiberius, dashed it to the ground, when it was merely bent, took a hammer and beat it back into shape. Whereupon the Emperor had him put to death as a dangerous person. Nowadays he would merely have been swindled out of his patent by way of punishment. Gilt and silvered pottery was produced in Mykenae; the silky red surface of the Roman *terra sigillata*, it is said, has recently been reproduced by coating a weakly fired vase with a layer of the finest clay, refiring, and polishing. [This method appears to have been used with Trojan pottery before glazing was discovered: see Dorpfeld's *Troja und Ilion*, 1253.] The Grecian and Roman technology is well described by Fester, but not nearly so completely as in Hoefer's delightful *Histoire*, which contains a wonderful account of this period. Lanoline (forgotten till about A.D. 1700), creosote, etc., were known. Indigo and Tyrian purple were used, but it was not known until the seventh century how to reduce them and bring them into solution as "vat dyes."

From the eighth to the thirteenth centuries the Arabs kept alive the Alexandrian chemical knowledge, which reached them by way of Syria. Harran, in Mesopotamia, the town of the Sabian heathens (who inherited some Hellenistic culture), was a centre of alchemy, and said to be the birthplace of Jabir ibn Hayyan—later identified with the Geber of the Latin works, then (Berthelot) separated, and now again (Holmyard) at least approaching him asyptotically. The "pseudo-Geber" is put by Fester in the fourteenth century, in spite of the fact that a MS. not later than 1300, evidently a copy of an older work, is known. "Geb[er]" (perhaps "another person of the same name") is mentioned by Vincent de Beauvais (*d.c.* 1260). Until Berthelot's time the Arabs were credited with the discovery of the mineral acids. These are not mentioned in Geber's principal work, *The Sum of Perfection*, but their preparation is described in another work attributed to him, *The Invention of Verity or Perfection*, in which he speaks of the "solutive waters" obtained by distilling nitre with green vitriol. The authenticity of this work has been strongly disputed; Lippmann suggests (following Berthelot) that the acids were discovered in Europe about 1300, probably in Italy. This view is reported by Fester, but the date has recently been put back about two centuries by Lippmann, so that the problem is hardly any nearer solution. The method of preparation of nitric acid, for the purpose of parting gold and silver, is described in some detail by Biringuccio (uniformly given as "Birineuccio" by Fester) in his *Pirotechnia* (1540, Venice). The Arabs made ceramics,



Distillation with Alembic in Jeronymus Brunschwyg's "Liber de arte dystillandi," 1500 (Johann Grueninger) which they took over from the particularly skilful manufacturers of Persia. In Damascus there was a continuation of the old glass-making industry: true enamels were also made for the first time. Salammoniac was an Egyptian product, obtained from the soot of dried camels' dung used as fuel. Borax is described as a flux. The Arabs were also practised in distillation: it is doubtful if they obtained alcohol, according to Lippmann, but they distilled large quantities of rose-water, and Alkazini (*c.* 1200) describes the distillation of tar and crude petroleum. They manufactured sugar, probably deriving their information from India.

When Hellenism fell to pieces, the chemical information which had been accumulated spread in two directions. Part of it, as stated above, went to the Arabs and came back to the West as alchemy—about A.D. 1200. Another part was handed down as technical tradition, and this came more especially from Byzantium. There are several of these collections of recipes, one of which is the "Liber ignium ad comburandos hostes" attributed to Marcus Græcus, which Fester (p. 42) puts down to "Constantinople, 1250." Hoefer, who first published the text in an easily available form (*Histoire*, 1, 491*ff.*), tentatively placed Marcus in the eighth century. Lippmann (*Alchemie*, p. 478) quotes Kopp, who quotes Gmelin, who quotes Jebb, in Bacon's *Opus majus*, as mentioning "a MS. in Dr. Mead's collection entitled $\pi\epsilon\rho\iota\ \tau\omega\nu\ \pi\upsilon\rho\omega\nu$ by Marcus Græcus." The reviewer finds that no such Greek title is mentioned by Jebb, who merely gives "Liber ignium," and there is no such title in Mead's catalogue of MSS. This is an excellent example of the way in which errors are propagated. In the *Liber ignium* there is a description of gunpowder: so there is in Bacon, in the form of an anagram. Prof. Fester inclines to the view that the discovery was made in China about A.D. 1150–1200. The "monk Berthold Schwarz" is no longer regarded as sharing the discovery with Bacon. Collections of recipes and technical information were published in the sixteenth and early seventeenth centuries: Cardan's *De subtititate*, Wecker's *De secretis*, Alexis of Piedmont's *Secrets*, Ulstadius' *Coelum philosophorum* belong to this category.



in Continuatione miraculi mundi
C
A Iſt der Ofen darin das holtz gebreſſet werde
B Der deckel darmit der Ofen geſchloſſen werde
C Die thür an dem Ofen dardurch man die kohlen aus nemb
D Seind die rohren darinnen ſich der holtzſafft Condenſirt vnd heraus rint
E Iſt ein fas darin der holtz eſſig laufft

Collection of Wood Tar from Beehive Ovens in Glauber's "Miraculum Mundi Continuatio" (first published 1657); Packe's English translation of "The Works of the Highly Experienced and Famous Chymist, John Rudolph Glauber," London, 1689

Another type of early technical treatise is Agricola's *de re metallica* (1556; the date 1546 given by Fester is probably incorrect: see Hoover's preface to his English translation) and Biringuccio's *Pirotechnia* (1540). These contain very detailed information on metallurgical processes. The separation of gold and silver by nitric acid was carried out in Venice at the end of the fifteenth century. [Venice was then a most important industrial centre: Tachenius in his *Hippocrates chimicus* speaks of the soap industry there in his time, and describes an accident to a workman who fell into a vat of boiling lye. This was drawn off, "but nothing was found except the harder bones."]

Many of the recipes given in these old collections might no doubt be foisted on the modern world by ingenious experts: the writer has come across several of them in the latest patent specifications.

In the seventeenth century one of the striking names is Glauber. He was a prolific inventor, although some of his discoveries seem to have been appropriated from others. He suffered by having his own best processes stolen from him and sold by more businesslike contemporaries, and decided to publish the whole of his secrets for the benefit of humanity. Among other things he distilled wood and separated the distillate into tar, acid and spirit. Robert Boyle also made useful discoveries, some of which were much in advance of his time. He describes distillation under reduced pressure (*Works*, abridged by Boulton, 2, 1700, 35 : "An instrument to distil in vacuo ").

The story is continued by Prof. Fester until the beginning of last century, the interest diminishing as the industrial period is reached. His book is a courageous attempt to deal with a vast subject within a reasonable compass, and cannot fail to interest all chemists. Apart from the absence of illustrations, one criticism may be offered. It is quite useless to refer merely to the title of a book running, in some cases, to over a thousand pages. Such a reference as "Vgl.auch Glauber, Furni novi," is useless.

In one case Prof. Fester discusses the cause of the great expansion of English trade at the beginning of last century (p. 119). He puts this down to "the absence, or early disappearance, of retarding monopolies, privileges and trusts." There is surely something in this, added to the fact that the goods supplied were good and cheap. Future historians will doubtless tell us something of the modern period.

PARLIAMENTARY NEWS

The Appointment of a Public Analyst in Gloucester

Mr. Chamberlain, answering Mr. C. S. Garland, said that his attention had been drawn to the terms and conditions offered by the County of Gloucester and the City of Gloucester for the appointments of public analysts to the county and city, respectively. He was aware that these authorities had appointed as public analyst a person whose qualifications did not appear to be within the terms of the regulations as to the competency of public analysts, and informed Mr. Garland that he was therefore in communication with those authorities as to the qualifications required for the post.—(June 25.)

Electricity Commissioners

Replying to Sir J. Remnant, Col. Ashley said that the expenses of the Electricity Commissioners were defrayed by the industry, and not from moneys voted by Parliament. The expenses, apart from the repayment of past advances, in respect of the year 1922–23, were £35,567, and the estimate for the year 1923–24 was £46,250. This included £15,227 in respect of salaries, and £20,273 for staff.—(June 25.)

THE EXISTENCE OF AMMONIUM HYDROXIDE IN SOLUTION

By Prof. T. S. MOORE

In a previous article (*Chemistry and Industry*, 1923, p. 343) I criticised the arguments used by Professor Caven (*Ibid.*, 1923, p. 164), and dissented from his view that the reactions occurring in aqueous solutions of ammonia are more likely to be

$$NH_3 + H_2O \rightleftarrows NH_4^{\cdot} + OH' \quad \text{(I.)}$$
$$\text{or } NH_3 + H^{\cdot} + OH' \rightleftarrows NH_4^{\cdot} + OH'$$
$$\text{than } NH_3 + H_2O \rightleftarrows NH_4OH \rightleftarrows NH_4^{\cdot} + OH' \quad \text{(II.)}$$

I wish now to deal with a second article (*Ibid.*, 1923, p. 448), in which Professor Caven defends his original position. As regards the argument based on the vapour pressures of hydrated salts, the facts reported by Caven and Ferguson are :—(*a*) The pressure of aqueous vapour at any one temperature, for the systems $CuSO_4.M_2SO_4.6H_2O \rightleftarrows CuSO_4.M_2SO_4.2H_2O'' + 4H_2O$, diminishes as M passes along the series K, Rb, Tl, Cs ; and (*b*) the temperatures at which 'rapid loss of water' occurs when the hexahydrates are heated in air are, for the same order of radicals, 33°, 55°, 60°, and 65° C. The correlation between these two properties in this series of compounds is obvious. Pending the investigation of the dihydrates it is a reasonable assumption, though by no means a certainty, that the same correlation will be found in this closely related series, in which case the dihydrated cæsium compound, which loses water on heating in air at a lower temperature than any other of the dihydrates, will be found to have the highest vapour pressure. The point raised by Professor Caven, that although the ammonium double salt has a lower vapour pressure than the rubidium compound, it loses water rapidly at a lower temperature than the latter, is so far from refuting my argument that it really tells against him. For whereas the compounds containing K, Rb, Tl and Cs show the definite correlation between vapour pressure and temperature of rapid loss of water already mentioned, the ammonium compound does not —*i.e.*, in this respect ammonium cannot be placed anywhere among the series of alkali metals.

In correspondence with me, Professor Caven has defined his views on the general question of variation of vapour pressure of systems containing hydrated salts with the basigenic character of the radicals they contain, and has stated that he does not advance any generalisation in this connexion. In fact, no basis, either theoretical or empirical, exists on which such a generalisation might be founded. Thus the results of Caven and Ferguson have no special significance as regards the basigenic properties of the radicals concerned, but with the exception of the discrepancy already mentioned, must be regarded simply as adding another case to those described by Tutton, in which, so far as the properties of its solid compounds are concerned, ammonium falls into a definite place among the alkali metals. But what reason is there for assuming that other properties of different systems containing these radicals; *e.g.*, systems involving solution, will be in the same order? If predictions of this kind may be made at all, one would expect them to apply most certainly in cases where the solid phase is still involved, such as solubility. Actually the solubilities recorded in Landolt-Börnstein (and the molecular percentage solubilities calculated from them) show that for the chlorides of the radicals concerned at 10° C., and for the corresponding alums at 0°, the order of radicals is not that found by Tutton and by Caven and Ferguson. If, then, the prediction fails for such a property as solubility, what confidence can be given to a prediction of the relative basigenic strength of $NH_4^{\cdot}$ in solution?

In the last part of his article Professor Caven quotes from Holleman's text-book a passage which implies that the salts of ammonia are hydrolysed in solution to a smaller extent than would be expected from the measured strength of ammonia as a base. This revival of the idea of 'abnormal hydrolysis' has been dealt with by Dr. A. E. Clarence Smith in a previous article (*Chem. and Ind.*, 1923, p. 578). It is worth while noticing, in addition, that Hantzsch, the original author of this idea, abandoned it when, in consequence of the theoretical paper of Kauffman, he was led to make accurate quantitative experiments (Ley and Hantzsch, *Berichte*, 1906, 39, 3149); and further, that the work of Lundén (*J. de chim. phys.*, 1907, 5, pp. 145 and 574) proves conclusively that for salts of ammonia and other nitrogen bases with weak acids, where the hydrolysis is sufficiently extensive to allow of accurate measurement, the theoretical relation between hydrolysis of salts and the strength of the base concerned, is fulfilled.

Thus all the arguments on which Professor Caven relies to prove that NH_4 is a strongly basigenic ion, break down on examination. Since, apart from his view on this point, Professor Caven urges no objection against equation II., and offers no evidence in favour of equation I., there seems to be no reason why the former should be discarded. I admit that there is no independent evidence that the undissociated compound shown to exist in considerable quantities in aqueous solutions of ammonia by Moore and Winmill is NH_4OH, but would point out that the same negative statement is true as regards the formula $NH_3{\cdot}H_2O$ proposed by Professor Caven for this compound. In such a case it is best to adopt the simplest hypothesis—that the undissociated compound has a configuration corresponding to the ions with which it occurs in solution.

SAFEGUARDING OF INDUSTRIES ACT

FORMALDEHYDE

The complaint by the Chemical Merchants and Users' National Vigilance Committee, that formaldehyde was improperly included in the Schedule of dutiable articles under Part I of the Act, was heard by the Referee, Mr. Cyril Atkinson, K.C., on June 15. The application was opposed by the Board of Trade, Messrs. Synthite, Ltd., and others.

Mr. K. Swan, who appeared for the Vigilance Committee, said that the world production of formaldehyde was now roughly 10,000 tons per annum, possibly more. He hoped to satisfy the Referee that formaldehyde, obtained from methyl alcohol, was not a synthetic product: there had been no building up by orderly steps which would make the process synthetic according to the previously accepted definition of synthesis. Formaldehyde was not described as a synthetic chemical, or as manufactured by synthetic processes in any of the textbooks. The Board of Trade asserted that formaldehyde was a synthetic organic chemical, a fine chemical and an analytical reagent. To call it an analytical reagent was a positive misnomer, and he could give instances to show that formaldehyde was regarded in the trade as a heavy chemical. The very varied uses of formaldehyde showed it was an industrial chemical. Over 90 per cent. of the output was used for industrial purposes, not more than 1 or 2 per cent. being used in pharmacy; its chief pharmaceutical use was in the manufacture of hexamine. Mr. Swan said that the Board of Trade stated that formaldehyde was a carbon compound formed by restricted oxidation of methyl alcohol in presence of a catalyst. But oxygen had not been added: the methyl alcohol had been deprived of its hydrogen, so that to say that methyl alcohol had been oxidised was not correct. He did not agree that until recent years, formaldehyde had been manufactured exclusively by fine chemical manufacturers. He took serious exception to the statement that formaldehyde was an alcohol derivative, and as such, belonged to another recognised group of fine chemicals. It was not an alcohol derivative, but a derivative of methyl alcohol, and was a paraffin derivative.

Mr. E. Parry confirmed the statement as to the method of producing formaldehyde with one exception; recent investigations by Le Blanc and E. Plaschke showed there was no oxidation at all, the formation of formaldehyde being due to catalytic dehydrogenation of methyl alcohol. He had never used formaldehyde or heard of its being used as an analytical reagent. Many trade journals had for many years past referred to formaldehyde as an industrial chemical, but *Kelly's Directory for the Chemical Industry*, 1919, the *Buyers' Guide for the Chemical Industry*, issued by the Society of Chemical Industry, 1923, and a publication by the Association of British Chemical Manufacturers (1922) did not state that formaldehyde was to be obtained from fine chemical manufacturers. After describing the pharmacopœial standards for formaldehyde, Mr. Parry said that the British Drug Houses list of chemical products contained three grades of purity, but he did not think that that indicated whether the chemical was fine or not. Mr. Parry said the statement that methylene glycol was formed in the formation of alcohol, but that, once the solution of formaldehyde was obtained, the methylene glycol present decomposed in the formaldehyde, did not agree with published statements. He could not disagree that formaldehyde was a remarkably pure product, but this did not correspond with information he had obtained from manufacturers outside this country, or from users. Dealing with the remark that formaldehyde was classified under the heading " Drugs and Fine Chemicals " in the *Oil, Paint and Drug Reporter* (U.S.A.), Mr. Parry observed that the difficulties of definition had become so great in the United States that only this month the Synthetic Organic Chemical Manufacturers' Association of the United States had attempted to define a synthetic organic chemical, but the definition arrived at was meaningless (*cf. Chem. & Ind.*, p. 481).

Dealing with the point that formaldehyde was classified in so many trade publications under the heading of " Industrial Chemicals," Sir A. Colefax submitted that the word " industrial " did not distinguish between fine and heavy chemicals ; chemicals were called industrial chemicals because their main uses were industrial. Answering further questions, Mr. Parry agreed that no organic chemist would be without formaldehyde in his laboratory, but it would be there as a reactive substance and not as an analytical reagent. He agreed that formaldehyde was a synthetic organic chemical if the methyl alcohol used had been prepared synthetically, but he pointed out that the synthetic method of producing formaldehyde was not practical, so that they had to start with methyl alcohol as a raw material and subsequent operations were in no way synthetic.

Sir A. Colefax stated that the United States Customs classified formaldehyde as a synthetic organic chemical, the definition of a synthetic organic chemical laid down by a United States Treasury Minute being : " Any substance which is known commercially as a chemical or drug and which contains carbon in chemical combination with other elements except cyanide, cyanamide, carbide, carbonates and bicarbonates of metals or inorganic radicles, and which has been produced by any chemical process other than that necessary to extract, isolate or purify the substance from a natural source, or to effect its separation from a more complex natural compound by hydrolysis, or to form a solvent."

On June 22, 1923, the cross-examination of Mr. Parry was resumed by Sir A. Colefax. Counsel asked a number of questions with reference to phenanthrene and anthracene dihydride with a view to eliciting witness's opinion as to synthesis. In reply to the Referee, Mr. Parry said :—" There are undoubtedly a number of bodies largely prepared by reactions which are so definitely those of the synthetic chemists and synthetic chemistry that although the molecule is not increased by carbon the mere act of introducing hydrogen into the anthracene ring is such a complicated synthetic operation that I do not think you could deny that anthracene dihydride was a synthetic body in spite of its not having a carbon compound attached to it." On this further questions arose as to the distinction which witness was drawing between the passing of a hydrocarbon to one containing more hydrogen, which he agreed was synthesis, and the passing from methyl alcohol to formaldehyde, which he would not agree was synthesis. But Mr. Parry continued to maintain that the production of formaldehyde from methyl alcohol was not a synthesis because hydrogen was split off and it was an ordinary oxidation process. Mr. Butler, of Messrs. Greef & Co., Ltd., gave evidence that he had not regarded formaldehyde as a fine chemical nor was it so regarded in the trade. Similar evidence was given by Mr. R. R. Wilkins, of Messrs. Victor Blagden & Co., Ltd., who said he regarded formaldehyde as an industrial chemical.

This concluded the evidence in favour of the removal of formaldehyde from the list of articles under the schedule to the Act. Sir A. Colefax, for the other side, first submitted to the Referee that he had no case to meet. He then suggested that on the evidence before him the Referee could not come to the conclusion that formaldehyde had been improperly included in the list. As the Referee held that there was a case to consider, Sir A. Colefax opened his evidence with some trade witness.

Mr. W. T. Bruce, of Messrs. W. T. Bruce & Co., stated that he had been dealing with chemicals for over forty years and that he had always classified formaldehyde as a fine chemical. He was followed in the witness chair by Dr. W. R. Walkey, the Managing Director of the London Chemical Works, who gave evidence of having started manufacture of formaldehyde since the passing of the Act. Mr. W. T. Allen, of Messrs. Allen, Craig & Co., who said he was a dealer in fine and heavy chemicals, gave evidence that he had not regarded formaldehyde as a heavy chemical. Mr. W. Gregory, an analytical and metallurgical chemist and a director of Messrs. William Gregory & Co., Ltd., gave his opinion that formaldehyde was fine chemical. This concluded the day's proceedings, which were continued on Thursday, June 28.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

A Great Week closed on Saturday last at Cambridge. It is perhaps not too much to say that the events of that week mark a very definite step forward in the advance which British Chemical Science is making. The choice of Cambridge as the meeting-place for the International Union for Pure and Applied Chemistry and for the meeting of the Society of Chemical Industry was a very happy one. I think that no other town which might have been chosen would have left the same impression on the minds of the foreign delegates. The meetings of the International, which occupied the first three days of the week, were noteworthy for the part played by the British representatives. Sir William Pope was an ideal chairman, and the "despised and rejected" Professor Armstrong (as he described himself later in the week) came into his own. Perhaps his verbal duel with Professor Bancroft was the best of his efforts and greatly pleased his audience.

The Most Picturesque of the ceremonies was the congregation on Wednesday, when honorary degrees were conferred on Profs. W. D. Bancroft, E. J. Cohen, Albin Haller, C. Moureu, R. Nasini, A. Pictet and F. Swarts. The stately procession, the pleasing manner of the Vice-Chancellor, and the sonorous speeches of the Public Orator all added to the dignity of the proceedings. I heard afterwards that there was one person who was a little taken aback. Earlier in the day, in trying to find the Arts School, he commandeered the services of an amiable gentleman to conduct him to the meeting-place only to discover later on that his guide was no less a dignitary than the Public Orator.

The Fitzwilliam Museum was used for the reception of the International on the Wednesday, as well as for the reception of the Society on the Thursday. On both occasions the Vice-Chancellor of the University and Mrs. Pearce were the hosts. I am inclined to think, however, that it was the smoking concert on the Wednesday night which assured the success of the Society's meetings. By that time all the members who were attending had assembled, and the function formed an opportunity for everybody to get to know everybody else, and a number of discoveries were made. We saw Prof. Armstrong in a new *rôle*. It says a good deal for the "atmosphere" of the concert that even this hero of a thousand fights should have been compelled, for a brief moment, to lay aside the protective armour with which he has surrounded himself, and reveal to us a very human but hitherto carefully concealed side of his character. The insistent demand for a speech from him we attribute to his intellect, but the applause at the close showed that the audience had detected something finer which perhaps many had not suspected.

The Annual Meeting opened with speeches of welcome from the Vice-Chancellor and the Mayor, who in their several ways extended a very cordial invitation to the members to participate in the various delights of the University and town. Then followed the President's address, which he read in abstract, but gave us sufficient to warrant our looking forward to reading the address in full, which we were able to do when *Chemistry and Industry* arrived in the afternoon. The ball at the Town Hall in the evening has already been described in the lay press as a brilliant function, but I was more interested in some of the byplay which went on among the senior officials of the Society. It was obvious that something rather serious had happened, but it was not until the following morning we discovered that Dr. Carpenter had been unavoidably prevented from coming to Cambridge to receive the Society's silver medal and to deliver his address. No wonder the officials were in a quandary; however, when we met the following morning in the Arts School, the President read Dr. Carpenter's letter, and having told us something of the origin of the medal, he called on Sir William Pope to give an abstract of Dr. Carpenter's address. It transpired that it had only been placed in Sir William's hands an hour before the meeting, but notwithstanding this, in the space of twenty minutes he gave what was truly described by those who had seen the paper as a masterly abstract. It was indeed a remarkable performance. Mr. E. V. Evans received the medal on Dr. Carpenter's behalf, and Mr. Woolcock wound up the proceedings with a short speech describing some of Dr. Carpenter's activities in chemical industry.

Dr. Aston's Lecture on "Isotopes" was another outstanding feature of the meeting. For clearness of thought and lucidity of expression it would have been very hard to beat. We had begun the day well, and were continuing it with growing interest. The garden party in the grounds of Sydney Sussex was delightful, and then at the close of the day came the dinner in Trinity College Hall. No similar function in other surroundings approaches the ascetic pleasure of a dinner given in a College Hall, but as to the speeches I will only say that to my mind they were not unworthy of the place in which they were delivered. Looking back on the week I cannot help feeling that it was most successful. It has enhanced the prestige of the Society, and done a considerable amount of good to chemistry, both pure and applied.

CHEMISTRY AT CAMBRIDGE

INTERNATIONAL UNION

The meetings of the Union Internationale and of the Society of Chemical Industry at Cambridge were an unprecedented success. They can hardly be separated, they formed two acts of the same play, and now that we have time to look back upon it we realise how good it was. The Union Internationale was well attended both by British and foreign representatives; Sir William Pope, Professors H. E. Armstrong, Crossley, Pickard, A. G. Perkin, Hopkins, Dixon, Barlow, Thorpe, Kipping, Hewitt, Lowry, McBain, Brame, Harden, Smithells, Drummond, Bedson and Barger, Messrs, Carr, Rideal, Marsh, Clarence Smith, Chattaway, Chapman, Gardner, Hulton, McNab, Coward, Mond and Miall attended, and most of these stayed for the whole or part of the meeting of the Society of Chemical Industry. France was represented by Professors Haller, Moureu, Bertrand, Boudouard, Lindet, Béhal, Messrs. Kestner, Marie, Kling, Deschiens, Gérard, Etienne, Lormand, Delépine, Marquis and some others. Italy sent Prince Ginori Conti, Professors Paternò, Giordani, Nasini and Parravano, Signors Bianchi, Pomilio and several others; America sent Professors Bancroft, W. A. Noyes, Hibbert, and others. The Dutch delegation was a large one, including Professors Cohen, Kruyt, Verkade and Mr. Prinz; from Denmark came Professor Biilmann and Mr. Warming; Professor Boedtker came from Christiania, Professor Minovici from Roumania, Professor Swartz and several others from Belgium, Professor Pictet and some others from Switzerland, and many others from many places. Their names form a long and distinguished list and their presence and that of the ladies who accompanied them ensured the success of the meeting.

THE CONFERRING OF HONORARY DEGREES

On Wednesday, June 20, the Vice-Chancellor, preceded by the Esquire Bedells and followed by the University Marshal, headed a procession clad in scarlet and other gay colours to the Senate House. Degrees of Doctor of Science (*honoris causa*) were conferred upon seven eminent Professors of Chemistry with due solemnity. There is a calm dignity about such proceedings which appears to be a survival from a period when trains and telephones did not exist and time was ampler than now. The Public Orator, Dr. Glover, made a short speech in Latin and introduced to the Vice-Chancellor the new doctors with seemly observations in Latin of which the following is a rather crude paraphrase or summary :—

First I present to you Albin Haller. Whatever is done in science in France they discuss in his Académie des Sciences; in that society are gathered all those who pursue such studies; over this assembly each year some renowned man presides. As he is worthy of such a distinction we to-day honour him and ourselves. Wilder Dwight Bancroft follows, our colleague in study and of our own kin, who, a second Ulysses, skilled in many things, adorns a new Ithaca with modern science. Next comes Ernest Julius Cohen from Holland, whose intellect, like that of Ovid, compels him to tell of the changed forms of new compounds. Another Frenchman follows, a professor in the Collège de France at Paris, Charles Moureu, one who by no means despises the most minute of substances but keenly investigates their ways.

To-day, while far-off Etna thunders with dreadful destruction, we greet, with special fervour, an Italian, Rafael Nasini, whom the Etruscan city, Pisa, well known to Virgil, has sent to us. He has chosen for study the volcanic vapours which are poured from the bowels of the earth towards the heavens and Albunea exhaling its dense gas. Now a Swiss approaches, the senior professor of the University of Geneva, Amatus Pictet, who has searched out the very foundations of matter, investigating the facts of the most rarefied vacuum. Next comes a professor from the Academy of Ghent, whose work there are many here present capable of explaining more fluently than I can; it is agreed by all who are engaged in that branch of knowledge that none excels Frederic Swartz. Blessed is that man who knows the causes of things.

The Fates do not give everything to all men; I was born in Arcadia, an unworthy student of the ancient Muses, happy to officiate in my little temple. You, who have done such great deeds, forgive me if, ignorant of the various languages you speak, I bid you all welcome in Latin.

This journal would attain to very unwieldy proportions if we attempted to give an account of the discussions on soap solutions, on tautomerism, on oxidation in vital tissues and on catalysis; a summary of the reports on these topics has already appeared and the discussions were both valuable and voluminous.

PRESENTATION OF THE PATERNÒ MEDAL TO DR. F. W. ASTON

Italy has produced great names in art, literature and science; in the science of chemistry the name of a distinguished Italian, Professor Paternò, is now given to a special medal to be presented to original workers in the science. The Paternò medal is a symbol of the esteem in which Prof. Paternò is held by a number of his colleagues in Italy, France, England, America and other countries. Professor Paternò is Marchesa di Sessa, a Senator of the Kingdom, and the head of an ancient Sicilian family; he is in chemical circles perhaps best known for the method he discovered of making phosgene, $COCl_2$, by the direct combination of carbon monoxide and chlorine, absorbent charcoal being used as a catalyst. He has also studied the preparation of various poison gases, and made investigations in other departments of organic chemistry. During the recent meeting of the International Union at Cambridge, the first Paternò medal was presented to Dr. F. W. Aston, F.R.S., in recognition of his discoveries of isotopes, and his measurements of the mass of their atoms.

Dr. Aston is both a chemist and a physicist, and one of his earliest publications was a joint paper with Prof. Percy Frankland, on some derivative of tartaric acid. In connexion with isotopes, Dr. Aston greatly improved on Sir J. J. Thomson's method of recording mass spectra, and by suitable adjustment of the electric and magnetic fields through which the atoms travel he obtained a method so accurate that it can be used quantitatively, and will measure the atoms to a nicety of one part in a thousand. He has since devised a new method which promises to be still more accurate, and to be applicable to a number of elements which have hitherto resisted treatment.

Sir William Pope took the chair on the occasion of the presentation of the medal and gave a brief and pleasant account of the creation of the Paternò Fund and some of the essential features of the work of Prof. Paternò. He was followed by Prince Ginori Conti, the President of the Italian Chemical Society and of the Italian delegation to the Union Internationale. He explained how on the seventy-fifth birthday of Prof. Paternò the fund was organised, and a triennial gold medal instituted, to be awarded to those who conspicuously excelled in chemistry and physical chemistry. He was particularly pleased to see present Sir J. J. Thomson, Sir Ernest Rutherford, and other Cambridge men of science, to whom the Italian chemists presented their greetings and congratulations, and called upon Prof. Paternò to present Dr. Aston with the medal. After this ceremony and a suitable speech by Prof. Paternò, Dr. Aston thanked Prince Ginori Conti and his colleagues, and called attention to the great importance, especially at the present time, of maintaining a close connexion between researches in chemistry and physics. Dr. Aston remarked on the great value of such awards, not only as an encouragement to those engaged in study, but as a means of retaining the international character of science and promoting agreeable relations between chemists and physicists in all countries. Sir J. J. Thomson and Sir Ernest Rutherford spoke with appreciation of the valuable work of Dr. Aston, and of the kindly manner in which a great Italian chemist, with the co-operation of distinguished Italian chemists and engineers, had on this occasion done honour to an English colleague. It was hoped the good relations between the two countries would long remain as cordial and happy as they now were.

At the final meeting of the Union Internationale, Prof. Cohen, of Utrecht, and Prof. Sakurai, of Japan, were elected as additional Vice-Presidents, and the invitation to hold the next Annual Meeting in Copenhagen was very cordially accepted. Having sketched in this slight and hasty manner some of the main features of the earlier meeting we come now to our own meeting.

* * *

THE SOCIETY OF CHEMICAL INDUSTRY

This was well attended, and from the social point of view, was exceedingly good. There were no papers on industrial subjects, and no visits to works had been arranged. "The Spanish fleet you cannot see, because it is not yet in sight." These omissions made it difficult for some members to reconcile their desire to attend the meeting with their duty towards their work. Desire said "Go!", Conscience said "Stay!". In future years it may be worth while to have just that minimum of applied chemistry which will be an adequate excuse for all except the most obstinate and inflexible conscience. It is not intended to cast any reflection on those who did attend the meeting; many of these got their work done by superhuman effort, concentrated in the two or three days prior to the meeting; others did their work at Cambridge, others merely postponed it until a more convenient opportunity arose. One should take a wide view of such problems; the man who eats oysters should not think of the pleasure it gives him, but of the remunerative employment which he provides for those who go down to the shore of Colchester or Whitstable. During the Society's meeting at Cambridge there was a sort of gaiety, a cheerfulness, even a light-heartedness from which we fear we have not yet entirely recovered. It began with the Smoking Concert, which was really an uncommonly good one. The conjuring, both amateur and professional, was most amusing, and how Mr. Kipping has managed to snatch the time for practising juggling, *de solido die*, passes our comprehension. There was some good music, and an amusing and very delightful speech by Professor Armstrong, who felt a just pride in the fact that two of his pupils were professors at Cambridge and his son President of the Society. This was some consolation to him when he reflected that years ago he unsuccessfully applied for a professorship at Cambridge himself. Singing is perhaps not quite our subject, but we think that the following shows that the Chemical Department at Cambridge does not confine its attention to optically active compounds with sesquipedalian names; the song was composed by Mr. Hxxxxs, and sung with great success by Mr. Harding.

THE CHEMIST'S LOT

(With apologies to the late Sir W. S. Gilbert)

When a crystallising substance looks like gravy,
looks like gravy,
And a prep. yields almost nothing else but tar,
else but tar,
The chemist wishes he was in the Navy,
in the Navy,
Or in Commerce, Church, or pleading at the Bar,
at the Bar.
When distilling flasks disintegrate with vigour,
-grate with vigour,
And flames and smoke obscure the wintry sun,
wintry sun,
Then is seen the Chemist's life in all its rigour,
all its rigour,
For the Chemist's lot is not a happy one.
Ah! when you carefully consider all its rigour,
all its rigour,
The Chemist's lot is not a happy one,
Happy one.

When your final product is a dirty ointment
And smells like nothing else you've met before,
It is hard to hide your bitter disappointment,
And cheerfully begin the prep. once more.
When you take a synthesis through several stages
And the yields get worse and worse as you go on,
You disbelieve the writings of the sages
With their stories of the clever things they've done.
Ah! when synthetic preparation's to be done,
The Chemist's "lot" is such a little one!

When a superheated dye solution bubbles
And the Red Guards gain another new recruit,
The remainder of the lab. forgets its troubles
And assists to clean the victim's face and suit.
When junior students smash SO_2 syphons
And all who wish to live have got to run,
The research-man-demonstrator (note the hyphens)
From these incidents derives a lot of fun!
Ah! when the matter is considered, all and done,
The Chemist's lot is quite a funny one!

R. T. M. H.

THE SOCIETY'S MEDAL

As the scrutineers of the ballot for Officers and Members of Council had not completed their task when the meeting adjourned on Thursday their report was not read until Friday morning, when it was announced that the following had been elected :—

President: Dr. E. F. Armstrong, F.R.S., (Re-elected).

Vice-Presidents: Dr. T. H. Butler, Mr. F. H. Carr, Professor G. G. Henderson, F.R.S., Mr. Emile Mond.

Ordinary Members of Council: Prof. P. P. Bedson, Dr. R. T. Colgate, Prof. A. R. Ling, Dr. J. Reilly.

The President announced with very great regret that Dr. Charles Carpenter had sent a message stating that he regretted he was unable to come to Cambridge to receive the Society's Medal and to deliver his address. He had, however, sent the notes on which his address was to be based. Dr. Armstrong said that the Council felt that the reasons which prevented Dr. Carpenter from coming to Cambridge must have been of very great weight. The Society's Medal was awarded to a scientist, a chemist who had contributed either to the advancement of science or to that of the Society. It was first awarded in 1896 to Mr. Glover of sulphuric acid fame, and since then it had been awarded to many other eminent scientists and chemists, including Dr. Perkin, Professor Ira Remsen, Mr. T. Tyrer, Mr. C. F. Cross, and Monsieur Paul Kestner. Dr. Carpenter had joined the Society 30 years ago, and he could be regarded as the prototype of the chemical engineer. During those years he had so developed the South Metropolitan Gas Company, of which he was President, that from the point of view of the application of science to industry it stood second to none in the world. Dr. Carpenter's policy, to provide those within the Company's area with so good a gas that nobody would wish to change it for any other form of lighting or heating, had only been made possible by the technical work he had initiated, lead, and in part contributed to.

The President said that he did not think it desirable to deal in great detail with Dr. Carpenter's work, but he wanted to feel that in saying little he left nothing unsaid (*cf. Chem. & Ind.*, May 25, p. 515). Commenting on Dr. Carpenter's work for the Society and for chemical industry itself, Dr. Armstrong reminded the members that Dr. Carpenter was President of the Society during the two critical years 1914 and 1915, and that he was instrumental with others in forming the Association of British Chemical Manufacturers, a feat which he—the President—believed would probably be found in future to have been fraught with greater consequences to the industry than almost any other of his many achievements. Sir William Pope then gave a brief outline of Dr. Carpenter's address and read extracts from the notes which he had received.

Sir William Pope said that Dr. Carpenter's address was a very comprehensive account of the past history of the gas industry, and its present condition, and an extremely illuminating exposition of what the author imagined the future of the industry would be. Dealing with the early history of the distillation of coal, he told how, in the *Transactions* of the Royal Society in 1739, the Rev. Dr. Clayton had communicated a paper, the first published on this subject, in which Dr. Clayton had said, "I got some coal, and distilled it in a retort in an open fire. At first there came over only phlegm, afterwards a black oil, and then likewise a spirit arose, which I could no ways condense; but it forced my lute, or broke my glasses. I then had a mind to try if I could save any of this spirit, and in order to do this I took a turbinated receiver, and putting a candle to the pipe of the receiver, whilst the spirit arose, I observed that it catched flame, and continued burning at the end of the pipe, though you could not discern what fed the flame. I then blew it out, and lighted it again several times; after which I fixed a bladder. I kept the spirit in the bladders a considerable time, and endeavoured several ways to condense it, but in vain."

Dr. Carpenter told of the early work of Murdoch and Watt on the production of coal gas, and then came what was a very characteristic touch on the part of Dr. Carpenter. He was primarily an engineer, and therefore one would not suspect him of having any bias towards chemical subjects. He had pointed out, in describing the conditions under which the gas industry was carried on, that we could look upon the whole industry concerned with the distillation of coal as a kind of circle, in the centre of which the actual process of coal distillation stood, and, radiating from this centre, ancillary to the actual process of coal distillation itself, was the enormous complexity of industries which were based on the utilisation of coal and its products. Commenting on this picture, he said that everywhere we met the hand of the chemist controlling these industries, but when we came to the primary operation, the destructive distillation or carbonisation of coal in the production of town's gas, we saw but little evidence of his work in the operations generally carried on to-day. The plant employed was, in principle, practically what it was a century ago. He did not mean to imply by this that no development had taken place; the retorts were larger and longer, and, being more resistant to heat, were worked at a higher temperature. Also, machinery had been substituted for hand labour in many of the subsidiary operations. These tasks were peculiar to the functions of the engineer, and he had performed them admirably. He was, of course, carrying out what was primarily his own particular task, *i.e.*, the mechanical operation of a particular process. Dr. Carpenter went on to ask, "What must be said of a process the raw material of which has been most inadequately studied?" and, throughout the whole of the Address, the keynote was to the effect that coal itself, the original raw material used in gas manufacture, had received far too little study at the hands of the chemist.

An account was then given of our present knowledge of the nature of coal, contrasting the very imperfect state of the information on coal itself with the very complete and highly complex knowledge that we now possessed of the constituents of coal tar. It was obvious that the picture the author had in mind was one in which he saw that the question of the composition of coal tar, and the utilisation of the enormous number of chemicals which it contained, had been carried to a very high pitch of perfection, and that many great industries had been founded upon this minute examination of coal tar itself. Apparently, he foresaw that ultimately we should be able to utilise coal in the same multiplicity of ways in which we now utilised the constituents of coal tar, by reason of getting, in the fullness of time, a more perfect knowledge of the composition and constitution of coal itself. It was easy to lament the small amount of information now available upon the complex questions of coal constitution, but only those in intimate touch with the subject could appreciate the great intricacy of the problem. Despite the considerable work carried out in recent years, it was still very bewildering to attempt to form a clear impression of the position to-day. One body of workers had studied the palæobotanical side with commendable results, others had submitted the coal substance to the action of solvents and to chemical reagents; another set of investigators had investigated the coking properties of coal and its general behaviour under heat. We were indeed only collecting bricks wherewith to build a temple of our knowledge, and as yet no master architect had arisen to design the structure. Until that was done we must, apparently, be content to study effects rather than determine causes. He believed that much greater knowledge of organic chemistry was required before this large accumulation of knowledge was correlated. The general idea which inspired Dr. Carpenter was that the engineer had done all he could, and it was now the part of the chemist to take the work in hand, to study the raw material, coal, with the same energy and efficiency as had been devoted to the study of the components of coal tar.

Discussing the behaviour of coal under heat Dr. Carpenter stated that Weyman had recently shown that a more rapid heat transference was effected by the gases evolved during carbonisation than by conduction through the charges or by radiation. With bituminous coal this method of heat transference was retarded by the formation of plastic layers, whereas with anthracitic coal heat transference by means of the gases could take place readily, and this accounted for the rapidity of carbonisation of these coals.

Discussing the coking of coal, Dr. Carpenter gave a brief account of the way in which the binding of the coal is affected by the oxygenated constituents of the coal itself, and concluded by saying that probably a true picture of the mechanism of the carbonising process was that it was one of high velocity, *i.e.*, that so soon as the coal particle was raised to the required temperature, the destructive distillation process proceeded very rapidly. The lag in the process arose from the time taken to raise the coal particles to the required temperature, and this was accentuated by the poor conductivity of the material and the formation of the plastic state through which the coal passed. This plastic state proceeded in layers in each coal particle from outwards inwards, and thus retarded the evolution of gas. When the plastic state was reached at the centre of the coal particle, it might be imagined that a turbulent state of affairs existed and the gases evolved had to pass the gauntlet of the maze of cells of the hot coke to gain their freedom. The designation of "destructive distillation" was no misnomer; in fact it was always a wonder to him (Dr. Carpenter) how so many of the complex hydrocarbons withstood the drastic treatment to which they were exposed.

Neglecting the many subsidiary factors influencing carbonisation, Dr. Carpenter said that the main factors which determined the value of carbonising results were :—

(a) The type of carbonising vessel and the pressure maintained therein

(b) The temperature to which the mass was eventually raised

(c) The rate at which heat entered the mass and the time taken for the mass to attain the final temperature

(d) The degree of heat and contact to which the volatile products from the coal were subjected

(e) The state of division of the mass under carbonisation.

The possibilities of low-temperature carbonisation were being slowly developed. The future of low-temperature tar was as yet unknown, but extensive investigations by Fischer and his colleagues had added appreciably to our knowledge of the subject. Apparently we were only on the fringe of the possibilities presented by low-temperature tar, and the future of the process itself might depend upon the results of this investigation. He was unable to appreciate, with the present state of knowledge of the low-temperature distillation of coal, the economic advantages of this process, and imagined that a suitable solid, smokeless fuel would be obtained eventually by the carbonisation of coal under special conditions, but at high temperature. The study of low-temperature tar had, however, proved of great value in interpreting the carbonisation process itself, and it might eventually result that the study of tars produced at various temperatures might be one of the keys to solve the problem of the carbonisation process.

In any discussion on the merits of various methods of coal carbonisation, it must be borne in mind that the adoption of any one method was generally determined by special local requirements, or the demands of the times. As coal was not only a source of gaseous energy, but also of tar products, nitrogen and sulphur compounds, development would take place along those lines which gave the highest yields of the particular products required. Whereas low-temperature carbonisation gave a comparatively low yield of ammonia, a very rich gas with a high yield of tar rich in low boiling-point paraffins, and a soft and easy burning coke, gasification with air and steam on the Mond system resulted in a high yield of ammonia and a very large volume of a low grade gas.

Dr. Carpenter emphasised the fact that the distillation of coal in the production of town's gas was not only a chemical industry, but that its development was only possible along lines to be laid down by the chemist and supervised by him. Vivid though Dr. Carpenter's dreams of the future might be, he had never yet visualised the community wholly supplied with gaseous thermal energy. He believed that gaseous and solid fuel had each their sphere of usefulness and that their systematic use would go hand in hand. He also believed that in the largest cities, as in the smallest villages, the gas works would be the portal through which all our raw coal would be required to pass, and whilst it was the chemist to whom we must look for the achievement of that ideal, it was certain that he would need all the assistance he could obtain from his brother worker, the engineer, who had no longer the monopoly of "directing the Great Sources of Power in Nature for the use and convenience of man."

The President, after thanking Sir William Pope for his admirable abstract of Dr. Carpenter's paper, asked Mr. Evans to accept the medal on behalf of Dr. Carpenter. Mr. Evans, he said, was the chief aide-de-camp to Dr. Carpenter on the chemical side of his work, and he was an excellent representative of the team which had aided and was aiding Dr. Carpenter. He felt that in handing the medal to Mr. Evans the Society was in a sense stimulating Mr. Evans and his colleagues at Greenwich and elsewhere to give even more arduous service to the cause of chemical industry, and in that way the medal would gain still more in utility, though primarily awarded to honour the work of a great man. In accepting the medal, Mr. Evans said that he knew Dr. Carpenter was deeply appreciative of the honour conferred upon him by the Society. They had only heard late on the previous evening that Dr. Carpenter was unable to be present, and he could assure them that the cause of Dr. Carpenter's absence was something quite beyond his control, because he had been looking forward with great enthusiasm to meeting the members again and addressing them. Mr. Evans then went on to give what he described as an "impression of a student's appreciation of a master," stating, however, that did he convey a true impression of his appreciation for the achievements of Dr. Carpenter, he might offend, owing to Dr. Carpenter's modesty. After describing

Dr. Carpenter's demand for a gas of constant quality, and the devices which he had designed and the organisation which he had built up to effect this, Mr. Evans thanked the Society in the name of Dr. Carpenter for the honour bestowed upon him and expressed his regret that the recipient had been unable to be present in person.

Mr. W. J. U. Woolcock, Manager of the Association of British Chemical Manufacturers, said that the man to whom the Society had given the greatest honour it could bestow, was a very many-sided man, but they were not so familiar with the various aspects of his character as they might have been because Dr. Carpenter repressed himself in many directions. He was a great lover of art, a student of literature, a born expert witness, as well as a great scientist, not to mention one of those chiefly responsible for the development of co-partnership. There was something about him which told his workpeople that he was a man who had other thoughts beyond his immediate work, and had thoughts and ideals for his workers. Both the Association of British Chemical Manufacturers and the industry owed a great debt to Dr. Carpenter. Previous attempts to unite chemical manufacturers in this country had failed until Dr. Carpenter applied himself to the task, seizing the opportunity and enthusiasm due to the war. The action taken by Dr. Carpenter, then President of this Society, in conjunction with the then Presidents of the Society of Dyers and Colourists and of the Chemical Society was most far-reaching. The question of the disposal of the chemicals produced by gas companies had always been one which might at any time have wrecked the industry, for gas companies on the one hand had the security of their Acts of Parliament and the necessity of disposing of their by-products to produce gas at a reasonable price, whereas the chemical manufacturers had no constant product such as gas to help them out in making and selling chemicals in this country. The problem of solving this possible conflict of interest between gas companies and chemical manufacturers was solved by the genius of Dr. Carpenter, and the solution was a monument to his tact.

DR. ASTON ON "ISOTOPES"

On Friday afternoon we listened to a capital address by Dr. F. W. Aston, F.R.S., on "Isotopes." Dr. Aston sketched the once rival hypotheses of Dalton and Prout, and showed how the knowledge we possessed during the nineteenth century compelled us to reject that of Prout. But the discovery of radioactive bodies seemed to show that bodies with identical chemical properties but different atomic weights could exist, and in the year 1910 Professor Soddy definitely put this idea forward as the only explanation which seemed to fit the facts. Such elements he called Isotopes, and in 1912 and 1913 Sir J. J. Thomson demonstrated the existence of two isotopes of neon. Dr. Aston was then assisting Sir J. J. Thomson in this work, and he schemed a detailed examination of the elements by a greatly improved method he had devised. The outbreak of war interfered with this piece of research, but so soon as the war was over Dr. Aston attacked the problem with vigour, and has now measured with an accuracy of one part in a thousand the mass of the various isotopes of hydrogen, helium, lithium, beryllium, boron, carbon, nitrogen, oxygen, fluorine, neon, sodium, magnesium, aluminium, silicon, phosphorus, sulphur, chlorine, argon, potassium, calcium, iron, nickel, zinc, germanium, arsenic, selenium, bromine, krypton, rubidium, tin, antimony, iodine, xenon, cæsium and mercury. Some few of these elements have also been measured by Dempster and some by G. P. Thomson, but to the credit of Dr. Aston must be placed by far the largest number of determinations to date. Of the isotopes investigated, all, with the exception of hydrogen and tin, have atomic weights which are whole numbers. It would not, however, be at all surprising if some other elements with high atomic weights have isotopes which are not whole numbers. These determinations are of far-reaching importance in the theory of chemistry, and the Society was both prudent and fortunate in securing the address from this brilliant experimenter. The next feature on the Society's programme was the Garden Party at Sidney Sussex College. The Master of Sidney Sussex and Mrs. Weekes welcomed us all very cordially, and showed us a number of interesting things; in their house and garden they are rich beyond the dreams of avarice, and many chemists who spend the bulk of their time in Widnes, St. Helens, Stratford and Silvertown, would gladly act as *locum tenens* at Sidney Sussex, if a temporary exchange of duties were mutually acceptable.

THE BANQUET AT TRINITY

The Annual Dinner was held in the hall of Trinity College on Friday evening, the President in the chair. The attendance numbered roughly 230, including a number of Cambridge guests. The loyal toast having been duly honoured, Mr. W. J. U. Woolcock proposed the toast of the University of Cambridge. The Society was extremely fortunate in meeting at Cambridge this year and in receiving the wonderful hospitality of the University. It was appropriate that the Society should come to Cambridge to join with members of the University in discussing scientific subjects because the foremost position held by Cambridge in the scientific world was well known. The members had had a most delightful time in Cambridge, and had come to the point when they had to express their thanks and to say how very sorry they were to go. He referred to Sir William Pope, who had represented both the members and the Cambridge authorities as occasion required, and to Mr. J. E. G. Harris, of the University chemical laboratory, who had contributed very much to the enjoyment of the members. He coupled with the toast the name of the Vice-Chancellor who had welcomed the Society to Cambridge and received the members in the FitzWilliam Museum. The Rev. E. C. Pearce came of a very distinguished line of Vice-Chancellors, and there were not many Vice-Chancellors with a longer record of service; in fact, only three Vice-Chancellors had maintained that office for three years. The Society would remember its visit to Cambridge, and in thinking of it would remember that the Vice-Chancellor of that time was a most perfect host. The Vice-Chancellor, responding, said that he had the honour of addressing an audience of chemists, but he was in ignorance of the rudiments of the science. He then referred to the University's Bill which was then being discussed in the House of Commons, and said that owing to the financial position at Cambridge the Government had offered assistance, but he hoped the Government would realise that Cambridge had not sold its independence. In conclusion the Vice-Chancellor said that he was very glad that the members had come to see the place where chemists were made, and hoped that in due time they would return.

The Master of Sidney Sussex College, the Rev. G. A. Weekes, proposed the Society of Chemical Industry. Sir William Pope had asked him to propose the toast, and as he was so little qualified to do it justice, he began to make inquiries about the Society and had been using his powers of observation. He was greatly impressed with the youthful vigour of the members of the Society, whether at a reception, dance, smoking concert or dinner, and from his observations he should say that they applied the same concentration of mind and youthful vigour when they dealt with serious problems. It said much for the Society's perspicacity that the centre of industry chosen this year for their meeting was the University of Cambridge. It would not be too much to say that Cambridge was one of the great power stations of the country, energy being supplied by the professors, teachers, and other investigators doing scientific work. Its staple industry was education, and he had observed with interest that the President had emphasised the necessity of combining the theoretical with the practical. If the Society was trying to teach the country this necessity it was doing a very great service, not only to the industry, but also to the nation. He coupled with the toast the name of the President, for whom he had conceived a very profound respect. In response, the President said that after Mr. Woolcock's speech it only remained to add the Society's thanks to the Mayor of Cambridge. They had had a busy week, almost a frivolous one, but there had been time to consider the inner meanings of things in a place such as Cambridge. They came to Cambridge as the embodiment almost of a new age because chemists were the embodiment of the first rank of industrial progress. As President of the Society, he might well say to Sir William Pope as President of the International Union, and paraphrasing the words of Bishop Latimer, "Play the man, Master Pope, for this day we have lit such a torch in Cambridge, the torch of a new chemistry, which I trust will never be put out." Those who had listened to the reports presented to the International Union had been struck by the fact that the subjects dealt with represented in each case the overthrow of past views of chemists. Something new had taken the places of those views. Dr. Aston, in his lecture, had advanced an entirely new conception of the most fundamental facts in chemistry, therefore he was justified in his exhortation to one of the greatest leaders of the present time. He exhorted everyone to resolve that the Cambridge meeting should lead to earnest striving for the advancement and betterment of the profession of chemistry.

Sir William Pope, in proposing "The Guests," spoke of the guests from across the Atlantic and the stimulus their work had given to modern chemistry. There were also representatives of other nations, including a very prominent representative of Italy, Prince Ginori Conti. Mentioning Prince Ginori Conti's work on the utilisation for power of the steam produced in volcanic centres, Sir William Pope said that when one considered the resources of this kind which Italy had one could understand that with such a man at its head Italy would be the country of the future. He then referred to Monsieur Paul Kestner, who was President of the Société de Chimie Industrielle, and remarked on the collaboration between that Society and the Society of Chemical Industry. He hoped that this collaboration would always continue and the only complaint he had to make was that Monsieur Kestner showed himself too seldom amongst the members.

In reply, Monsieur Paul Kestner said that the President had made a grave error in asking him to reply to the toast. The honour of replying rightly fell to a guest, and he asked by what right the Society had considered him as a guest. He had joined the Society thirty-five years ago, was one of the senior members, and had formed many precious friendships among generations of eminent members. However, he would lay aside his dignity as a member of the Society and become like Maître Jacques in Molière's comedy: Jacques was both coachman and cook, so when his master wanted to speak to the cook he removed his coachman's hat and appeared dressed as a cook. Monsieur Kestner therefore would now appear as a cook; indeed chemists were often called cooks. In making such a comparison he was sheltered by the authority of a special correspondent who had represented *Chemistry and Industry* at the recent Pasteur Celebrations. That special correspondent, in the columns of *Chemistry and Industry*, had declared and proved Pâté-de-foie-gras to be a synthetic organic chemical. After addressing Sir William Pope in French, he expressed the thanks of the foreign guests for the hospitality of Cambridge and pointed out that the annual meetings of the Society were attaining more and more effect in establishing and tightening the bonds of friendship between scientific and technical chemists of every civilised nation. Unfortunately academic duties had prevented many from accepting invitations to join in the meetings during that week. Last year the annual meeting of the French sister society clashed with that of the English society, and this prevented many British friends from visiting Marseilles, where the meeting was held. He hoped in future arrangements would be made to prevent the various annual meetings from interfering with one another. Such an arrangement was all the more important in that French chemists could not regard any of their own celebrations as complete without the presence of their English colleagues, and he could assure them that an identical view was taken by the chemists of every nation represented in the International Union. Neither English nor French provided him with sufficiently eloquent terms with which to thank the University, the British Federal Council and the Society of Chemical Industry for the cordiality of their reception, and he paid special tribute to Sir William Pope who had rendered great service to his country by conferring upon it a reputation for cordiality and friendliness.

EXCURSION TO ELY

Throughout the week the weather steadily improved; the earlier days were grey, showery and bitterly cold, but we had pleasant conditions for the garden party at Sidney Sussex, and for our one excursion the weather was superb. We motored to Ely in charabancs, and were met by the Dean, who very kindly devoted the greater part of the morning to showing us round and explaining the history of the building and the features of special architectural interest. There was ample time to see the Cathedral, and after the preliminary tour one could spend a quarter of an hour admiring the late Norman nave or the Early English choir. And after lunch we gradually made our way to our homes.

Most of those who attended the meeting at Cambridge agreed that an occasional visit to some University centre is very desirable. Hitherto our meetings have been deliberately held in industrial centres and visits to works have been conspicuous features. It is well every few years to have such a meeting as this; it is good for the Society to become better acquainted with the life, the professors and the laboratories at our old Universities. It is perhaps good for the Universities to have fuller opportunities of meeting manufacturers and works chemists. The President in his address dealt with the education question from the point of view of the manufacturer, and he by no means covered the whole field of this problem. Some day this must be discussed again, and an exchange of views will take place which will be more useful after such an experience as we had at Cambridge. The geniality of our reception, the great hospitality, both official and private, shown to us, and the pains taken by all to make our visit both useful and happy have made a lasting impression on us. Naturally the President and Honorary Treasurer and Honorary Foreign Secretary were present; other members of the Council who attended were:—Messrs. Ardern, Burrell, Butler, Bedson, Cranston, Carr, Cox, Colgate, Garland, Hinchley, Jones, Levinstein, Monier-Williams, Morgan, Marsden, Maxted, Radcliffe, Trobridge, Thompson, Woolcock, Waterfall and Young. Other members of the Society who attended for the whole or part of the meeting were:—Messrs. Andrews, Anderson, Adan, Byard, Bolton, Barry, Boyce, Bowley, Burford, Barber, Bennett, Boardman, Bernard, Prince Ginori Conti, Messrs. Brown, Braunholtz, Berry, Blizzard, Chaston Chapman, Cross, Cullen, Collett, Clayton, Chapman, Dunningham, Damon, Davies, Drummond, Davis, Dorée, Greenwood, Goldsmith, Greenfield, Goodwin, Gibson, Heaton, Hart, Hill, Horner, Hooper, Hilditch, Horton, Humphries, Jerdan, Jennison, Jordan, Johnston, Jones, Kanga, Kestner, Lomax, Lessing, Leonard, Mann, Mason, McWilliam, Marlow, Morrell, Marshall, Macadam, Moore, May, McLaren, Ogg, Phillips, Procter, Pickard, Rodd, Roff, Radford, Robinson, Smith, Sibbald, Sturrock, Sutton, Stuart, Tainsh, Wood, Walker, Wright, Weyman, Wright. One of our lady members (Miss Dorothy Webster) was able to attend, and about fifty members were accompanied by their wives, so that the attendance altogether was a large one. The General Secretary (Dr. Longstaff), the local organiser (Mr. J. E. G. Harris), and the members of their staffs had a great deal of hard work in organising the functions so successfully, and must feel pleased that all enjoyed themselves so thoroughly. The other officials of the Society attended, but the meeting was to them a holiday.

The Council Meeting held in the Arts School in the morning of June 21 has not been so far officially reported, but we are informed and verily believe that it was decided that next year the Annual Meeting will be held in Liverpool. After the Council Meeting the Society was formally welcomed to Cambridge by the Vice-Chancellor of the University and the

Mayor of the Borough, and then the President delivered his address. Although this has already been published, there are certain passages in it which will furnish us with topics for comment, and it will be convenient to summarise them in this article.

THE PRESIDENT'S ADDRESS

Industry cannot afford to neglect chemical science and its teachings. Just as in the domain of sociology those who disregard the past are not likely to cherish any real visions for the future, so in industry neglect, that is, disregard of science, will inevitably lead to failure to progress. There can be no question that the future of industry largely depends on the application of scientific principles to production, and that chemists should be exceptionally competent to advise on such matters.

In any technical business—and all manufactures are highly technical nowadays—so long as all goes well the chemist is scarcely required, production being a question of organisation and management. But things never do go well for a long period of time ; difficulties are always arising, and it is then that the co-operation of the technical expert—of the scientifically trained man, the chemist—is required.

As regards those entering industry, I think many of my colleagues will agree with me that the time is ripe for a Conference with the teachers and a broad exchange of views either in public or in private where frank speaking can be the order of the day. I think I am justified in saying that we manufacturers find it very difficult to get the type of man we require. Possibly our Society can organise such a Conference, and I have in mind the utility of a somewhat similar meeting with Professor Meldola in the Chair, held under the auspices of the Institute. My remarks must not be held to place the blame on the teachers ; perhaps the material they have to work on is unsuitable.

The object of industry is definitely financial ; the object of industrial research is to work out new processes or improve existing onces. Investigations which have for their object the solution of special difficulties of particular processes and the utilisation of waste materials are not researches in the true sense of the word, although the solution of such problems would be to the financial advantage of the industry. These are matters more for the particular firm than for a research association.

Any assemblage of men of science willing to face the facts will agree that science, scientific method, and scientific research have not yet won that position within the realm and its industries that is requisite if we are to maintain our place among the nations.

It is desirable in my opinion to make a definite pronouncement on the need of co-ordinating in some way or other our various chemical societies, even at the risk of repeating much of what I have said during my visits to the sections.

* * *

It was pleasant to wander about the Colleges, to admire the Chapel of Kings, the Combination Room of Peterhouse, the gardens of Magdalene, the spacious court of Downing, the quaint hall of Queens, the bridge of Clare, and the score of other beauties which we had brief chances of enjoying, to see the members of the Society

Come forth by twos and threes,
From the broad tower of Trinity,
From the green gate of Caius.

Six centuries of civilization, of history and of learning cannot be properly treated in a few columns of ephemeral chemical news.

* * *

The Reception by the Vice-Chancellor of the University at the Fitzwilliam Museum may have pleased some of the guests. Personally we should have preferred to have spent a few hours wandering about and seeing the treasures of art, not distracted by friends and acquaintances, by ices and cakes, by greetings and jests. The pottery, the majolica, the pictures and the manuscripts are superb, and we hope in the future to have due time to see these in a leisurely manner. It is hard to have the latest gossip from Liverpool, and the opportunity of seeing a Corot at the same instant of time. It is not the fault of those who provide so much for us, but our fault for possessing an insufficiently nimble mind.

* * *

In due course we made our way to the Guildhall, where the band and the floor were both good. The arrangements for dancing and sitting out were stated to be excellent, and the reception enabled both the Cambridge residents and the chemical visitors to become better acquainted.

At the Dance we noticed our President gaily disporting himself and apparently enjoying it. This is all very well for the young, but you wait until you get a bit grey, as Horace puts it :—

Sperne, puer, neque tu choreas,
Donec virenti canities abest
Morosa.

One lady who seemed to have neglected her original partner for a temporary co-ordination with the President was chided in suitable terms and overheard to remark to the neglected swain in a soothing voice :—

Though you be treacherous as audit
When at the fire you've lately thawed it,
For E.F.A. no more I'd care
Than for their plate the Dons of Clare.

Perhaps some local reader may explain this abstruse allusion to us. In any case we ought to be grateful to our President for his strenuous and successful advocacy in support of a dance. It will no doubt become a regular feature of our Annual Meetings, and the older members of the Society must make assiduous practice compensate for their lack of youth.

COLOUR USERS' ASSOCIATION

The annual meeting was held in Manchester on June 19, the chairman, Mr. H. Sutcliffe Smith, presiding. After reviewing the activities of the various committees of the Association, Mr. Sutcliffe Smith referred to the Dyestuffs Advisory Licensing Committee and said that the chief difficulty with applications was on the score of price differences. The Licensing Committee stated officially on September 30 last that, temporarily, applications would be granted when British prices were more than three times pre-war level and higher than current foreign prices. If a colour could be made here, the British makers were given the opportunity of supplying it at the foreign price quoted or at three times pre-war price, whichever was the higher. If the makers could not do this, the user was granted a licence to import.

In discussing the work of the Dyestuffs Industry Development Committee, Mr. Sutcliffe Smith urged it to tackle the cost of production, the prevention of overlapping and the interchange of intermediates, so as to reduce the price of British-made dyes. The Committee might also consider how to facilitate the production, at an early date, of dyestuffs not yet made here, and for which import licences were now issued, the import value during 1922 being :—Germany £375,675, Switzerland £694,740, other countries £33,404, a total of £1,103,819. He deplored that the committee had not executive power, so that constructive views for placing the dye-making industry on a better footing could be carried out. We were called upon not only to pay high prices for home products, but the import prices were at a very high level, the average price per pound of finished coal-tar dyestuffs, excluding indigo and alizarine, having increased from 11·7d. per lb. in 1913 to 79·2d. in 1920, 66·7d. in 1921 and 65·8d. in 1922. A deputation had interviewed the President of the Board of Trade to urge that British makers should reduce their prices to a maximum not exceeding three times the pre-war level and that if the makers refused to do so, the Licensing Committee should grant licences to import foreign dyes and apply a similar factor to the prices of reparation dyestuffs. The request to reduce prices from 300 or 400 per cent. to 200 per cent. above the pre-war level was not unreasonable, as at present the whole cost of establishing the dye industry in this country was being borne by the users. A further serious aspect of the situation was the effect of the high prices of British products on the prices of foreign colours sold in this country, the foreign producers taking full advantage of the artificial state of the British market due to the Dyestuffs Act. The average value of colours imported from Switzerland in 1922 was 101·5d. per lb., approximately seven times the price in 1913, whereas the selling price of foreign colour was less in France, Italy and Germany. Further, reparation colour was sold by the Board of Trade at a large profit on the same high scale, so we were deprived of competition from lower rates in that direction, whereas had those prices been reasonable, they would have tended to reduce foreign prices. We thus appeared not only to be subsidising the British dye industry and increasing revenue to the Treasury, but supporting the foreign colour-maker as well. He had no reason to doubt that the British makers were making 80 per cent. of the colour used in this country, but he could not account for the imports ; if these represented only 20 per cent. of the total consumption, the total cost to the users must be many times greater than was realised. Imports of foreign colours, exclusive of intermediates, in recent years equalled an average annual import of 5421 t., worth £3,472,793. It was fair to assume that a large stock was carried forward from 1920 imports to 1921 and 1922, so that if British makers were providing 80 per cent. of requirements, the total colour used was well up to pre-war quantity. He could not agree that the consumption much exceeded 60 per cent. of the normal. It was evident, however, that a considerable tonnage of imported colour could be manufactured here and thus enable the makers to increase output and bring their prices down. If the British maker could not reduce prices without financial assistance, then the Government should give a grant in aid. There was a definite pledge to the users that the cost of establishing the industry should not fall unduly upon the using industries, and, remembering that the establishment of the industry was necessary for national security, it was only fair that the nation should bear its proportion of the charge. Recently it was stated in the House of Commons that the total sales of reparation dyestuffs up to March 31 last were over £1,000,000. If the total proceeds from selling reparation dyestuffs were placed at the disposal of the British dye-makers through an independent committee, it would probably form the basis of a fund to support the industry for another two years. Describing the procedure for obtaining reparation dyestuffs, Mr. Sutcliffe Smith observed we were not making the fullest use of the facilities afforded by the Reparation Agreement, and the sale of reparation dyestuffs was being largely used, not directly to assist the users, but as a means of obtaining additional revenue for the Treasury. It was time to review the procedure of obtaining reparation dyestuffs in the light of the experience of the past two years. A standard list of essential colours made in Germany but not made in this country had been prepared by the users and agreed to by the British makers, and he suggested that this list should be used as the basis of a new reparation arrangement with the German Government in consultation with the Association and that the selling prices should be fixed by an independent committee collaborating with the users. The occupation of some of the German dye-works by the French and the removal by them of part, at least, of the stocks was of serious interest to colour users in this country. There was, as yet, no official information on the course which the French and Belgian Governments proposed to adopt with regard to the stocks seized, but he was satisfied that the British Government was closely watching the position and taking all possible steps to safeguard British rights.

SOCIETY OF GLASS TECHNOLOGY

The last ordinary meeting of the session 1922-23, was held in Leeds on June 20.

The first paper was presented by the President, Prof. W. E. S. Turner, D.Sc., his subject being "Specifications in the Glass Industry." Prof. Turner pointed out that certain types of glass, *e.g.*, optical glass, were bought on specification and had to conform very strictly to certain properties. But in the enormous industry that produced containers for liquids and solids, no one seemed to have attempted to make or even purchase on the basis of specification. Several recent cases emphasised that lack of precision in the industry. For example, a fairly recent law case was fought round the quality of bottles supplied, and the evidence showed that, so long as the purchaser obtained something which had the shape of a bottle, the actual quality of the glass was apparently not specified. Several other cases of note had recently arisen, all pointing to the need of deciding to what specification different glass articles should conform. If the glass industry were to insist that furnace-material makers should provide refractories, for example, to specification, then the glass manufacturers themselves must at least show they were prepared to supply their own goods to specification. Prof. Turner then dealt with specifications which he thought might be made the working basis for common articles such as medicine, beverage and other bottles.

Mr. Th. Teisen, B.Sc., then contributed some "Notes on the Design of Pot Arches," illustrating his remarks by means of lantern slides. Criticising the old type of pot arch, Mr. Teisen said the flue outlet for burnt gases at the back wall near the bottom was certain to give cold pockets inside the furnace, but the ensuing lack of proper heat distribution could be somewhat helped by longer soaking, as this tended to equalise the heat. The fire boxes being open, the fire itself was not under proper control. An experienced fireman, however, would endeavour to overcome this by his method of firing, which was by no means so simple as was commonly assumed. The Continental type, with direct fired furnace, fire-box below, combustion flues and air flues leading to the uptake at the back of the chamber, and fumes passing through holes in the floor near the front and thence to the chimney, was a better design; but the arranging of it in the glass-house was not so practical. With the entry of the gas-fired pot furnace in the glass industry, a demand had arisen for a more modern type for heating pots. Mr. Teisen then described a gas-fired recuperative pot arch, which he designed some years ago, and which proved a success. He also described a pot arch at work at Messrs. Moncrieff's works at Perth, where during the first stage of burning, a low fire was kept on the grate, fed through the ash door. The secondary air slide was closed, and the furnace was in other ways directly-fired. For the purpose of driving out the natural and the combined water without producing surface cracks, water was kept dripping on the firebars, as well as on a plate arranged in front of them, thereby producing a certain amount of steam, which helped to prevent the surface parts from drying too quickly and allowed the moisture in the inside to evaporate at the same rate as that in the outside. That type took up little space and gave satisfactory results.

A paper entitled "Notes on the Ashley Bottle Machine" was read by Mr. S. English, who remarked that to one familiar only with modern glass-forming machines it might be surprising to hear that the home of bottle-making machinery was on this side of the Atlantic; but such was the case, and it was only after the possibility of making narrow-mouth bottles satisfactorily by machines had been proved here, that such bottle-making machinery was introduced in America. The first machine to make narrow-mouth bottles at all satisfactorily was designed and built by H. M. Ashley at Ferrybridge (Yorkshire), and it came to be developed in the following way. About 1866, the postmaster at Ferrybridge, Josiah Arnall, had occasion to go to the bottle works, which were situated within his district, and after seeing the way in which bottles were gathered, marvered and blown, he conceived an idea, which he thought might enable bottles to be blown by machinery. He submitted his idea to a prominent South Yorkshire bottle manufacturer, but apparently it was too crude or too revolutionary to be taken up. Nearly twenty years later H. M. Ashley, the manager of an iron foundry near the post office, went to live with Arnall, and there can be no doubt that Arnall discussed with Ashley his ideas concerning the possibility of blowing bottles by machinery. As a result of such discussion Ashley built an experimental machine in which glass was poured into an inverted mould, which was fitted with a plug to form the inside of the neck and with a movable top plunger. When a charge of glass had been placed in the mould, the sliding plunger was brought down on top of it, thus pressing it down around the fixed plug and forming the neck. Compressed air was then admitted through the plug, blowing up the bottle and at the same time raising the sliding plunger to the desired extent. Such an arrangement was very simple, and was naturally unsuccessful, but it had sufficient good points to cause Ashley to try to develop it into a useful machine. The first step in its improvement appeared to have been an appreciation of the fact that three moulds were necessary, one for forming the neck of the bottle, the second for giving a preliminary form to the main body of the glass, and the third for blowing the finished bottle. This provision of a ring mould, parison mould and blow mould was the foundation on which all Ashley's experimental machines were built, and has been incorporated in every successful machine since.

CHEMICAL SOCIETY

Eight papers were announced for reading at the meeting of the Society on June 21. For the presentation of these the time requested by the authors totalled two hours ten minutes apart from any time occupied by discussion or reply. The President, Prof. Wynne, therefore limited the time for the reading of each paper to fifteen minutes, expressing the hope that in reality ten minutes might suffice. One author took at least his full quantum; the rest, it is to be feared, sacrificed lucidity to brevity.

(1) In "The Constitution of the Higher Oxide of Nickel," Mr. O. R. Howell dealt with the composition of the precipitate formed when nickel sulphate is precipitated with alkaline hypochlorite. The higher oxide formed is unstable, and on decomposition the mean composition falls below that of the sesquioxide. The main reactions are :—

$$\begin{array}{lcl} 2\ \mathrm{NiO_2} & \overset{\mathrm{NaClO}}{\longrightarrow} & \mathrm{Ni_2O_3} \\ \mathrm{NiO} & ,, \ \rightarrow & \mathrm{NiO_2} \end{array}$$

intermediate combinations such as $\mathrm{NiO_2,3\ NiO}$ being formed. The formation of the higher oxide $\mathrm{NiO_2}$ has its counterpart in the oxide of cobalt $\mathrm{CoO_2}$, which explains the action of cobalt oxide CoO as a catalyst in the production of oxygen.

(2) "The Relationship of the Tautomeric Hydrogen Theory to the Theory of Induced Alternate Polarities," by F. Allsop and J. Kenner. Dr. Kenner criticised the reaction of Macbeth and Pratt, *e.g.*, $2\mathrm{XC\ (NO_2)_3 + N_2H_4 + 4KOH = 2C\ (NO_2)_3K + N_2 + 2KX + 4H_2O}$. He considered the ordinary theory of induced alternate polarity gave only a partial explanation of such reactions, and that the tendency to acquire a tautomeric hydrogen atom provided a better explanation. Prof. Thorpe pointed out that not any one condition determined the course of a reaction, and to any one explanation there were many contradictions.

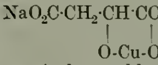
(3) "The Relative Influences of Water Vapour and Hydrogen Upon the Combustion of Carbon Monoxide—Air Mixtures at High Pressures," by W. A. Bone, D. M. Newitt and D. T. A. Townend. Prof. Bone showed the result of combustion of carbon monoxide with air, dry, saturated with moisture or with actual excess water present or with hydrogen in addition, in a special bomb apparatus employing an initial pressure of 50 atmospheres. Curves were given to show the pressure readings at intervals after combustion or explosion. The author explained that his results appeared at first sight to be at variance with those of Dixon and of Wheeler, but that in reality they were not so, the apparent non-agreement being due to different conditions in the respective experiments. The contention that nitrogen is made "active" by radiation was merely mentioned, the proof of this being left for a subsequent paper. Interesting spectroscopic evidence in conjunction with Prof. Fowler was given that complexes were formed when carbon monoxide burns in moist air.

(4) "Electron Valency Theories and Stereochemistry," by S. Sugden. The author pointed out that difficulties arose in applying either a static or dynamic theory of valency to the facts of stereochemistry. Replacing a double bond by a covalency and an electrovalency will not account for the existence of geometrical isomerides. Dr. Ingold pointed out that the facts of chemistry given by van't Hoff were vital, and modern theories must take account of them.

(5, 6) Two papers were communicated by Mr. I. W. Mark : "Metallic Hydroxy-acid Complexes." Part I., Cuprilactates. "Metallic Hydroxy-acid Complexes." Part II., Cuprimalates, their formation, properties and composition. The importance and number of metallic complexes with hydroxy-acids and polyhydric alcohols was shown. Any attempt at classification must account for points of similarity or dissimilarity between these compounds and the esters formed between compounds containing hydroxyl groups and, say, boric and phosphoric acids. Normal cupric malate underwent a peculiar change when dehydrated ; thus :—

$$\mathrm{CuC_4H_4O_5 \rightleftarrows HCuC_4H_3O_5}$$

Six metallic salts of the latter (cuprimalic acid) had been isolated and analysed. For the sodium salt



$$\begin{array}{l} \mathrm{NaO_2C{\cdot}CH_2{\cdot}CH{\cdot}CO} \\ \qquad\qquad\qquad\quad\ |\qquad\ | \\ \qquad\qquad\qquad\quad \mathrm{O{-}Cu{-}O} \end{array}$$

was suggested.

The comparatively stable nature of the compound was perhaps due to ring formation. When such a ring formation was impossible, *e.g.*, in the case of sodium cuprilactate, the compound was readily hydrolysed.

(7) "Ring Chain Tautomerism." Part VII. "The Mutarotation of the Sugars." By J. W. Baker, C. K. Ingold and J. F. Thorpe.

(8) The last paper, "New Halogen Derivatives of Camphor." Part III. $\alpha'\beta$ and $\alpha'\pi$ dibromocamphor, by H. Burgess and T. M. Lowry, was held over by Prof. Lowry for want of time.

CORRESPONDENCE

THE OBJECT OF INDUSTRY

Sir,—Among so much that is wholly acceptable in Dr. Armstrong's Presidential Address it may appear hypercritical to direct attention to one phrase in it; my justification for doing so is that it lies so near the heart of the matter.

Is it true that "the object of industry is definitely financial"? If it is, possibly that explains why there are so many chemists judged to be failures; for there will be few who identify finance and life.

Surely the object of industry is something very much larger and better than a merely financial one. Profits, salaries, wages and dividends may be necessary, but in a really successful industrial concern they are among the by-products—the *means* to the end.

An object is always and inevitably an object of life; and the object of industry, it seems to me, is to further the objects of its customers.—I am, Sir, &c.,

Solihull, June 24 Henry L. Heathcote

"LUCIFER" v. "CALORIFER"

Sir,—Why Prof. Bone should seek to make me a co-respondent in this action I do not understand. I seem to be the buffer for all ribaldry in the scientific Press. Not long ago a certain "Age" attributed to me the authorship of sundry beery piscatorial utterances uncomplimentary to worshippers of the hydrogen Ikon. Now I am thought to be calorific, though I am as cool as a cucumber. Next I shall be told I am in orders in a Yorkshire Dale and blamed for my ignorance of lead.

Surely Prof. Bone does not expect me to advise without fee. He mentions none nor does he send a retainer through you. If he be serious in wishing for my opinion, I may say I should charge on distance, at superior surgical rates and extra for my report. Business men tell me they only value opinions when they have paid through the nose for them and I have no wish to waste *my* time; in saving Prof. Bone's, I should be paid at least the value he places upon his—with a *pour boire*. "Calorifer" must have been a simpleton to have attempted to aid him gratuitously; after reading the correspondence I, at least, shall not make the mistake. Still, as a chemist, one has duties to the elements, and, maybe, later on I shall feel called upon to intervene as King's Proctor, if nitrogen be further aspersed—then I shall expect you to raise a subscription on my behalf as a defender of the classical faith.

Prof. Bone seems himself to vibrate to carbonic oxide and to suffer from consequent lag of memory. At his request I paid a gratis visit, some time ago, to his laboratory and studied the linked sweetness of his long-drawn-out records. I well recollect coming to the conclusion that the peculiar lag which he has observed was due to the incidental interaction of azote and oxygen; I also recollect telling him so. If I were "Calorifer" I should refer his speculation, not to the "Liverpool School"—whatever that may be,—but to the department for mental defectives.

Perhaps by the autumn Prof. Bone will have learnt to describe his work in terms which even the oldest of us can understand, and not need to call upon any Daniel to interpret the message before him. I trust the case will be now taken off the list.—I am, Sir, etc.,

Henry E. Armstrong

Lewisham, S.E. 13
June 24

CHEMICAL JOURNALS IN JAPAN

Sir,—Supplementing the interesting letter of Mr. Akira Shimomura on this subject, may I call attention to the publications of the National Research Council of Japan to which he does not allude?

Following conferences in London and Paris in 1918, of the majority of Allied and Neutral Powers, the Japanese Diet passed the necessary Bills in July, 1920, and on August 26 of the same year the Constitution of the National Research Council of Japan was promulgated by Imperial Ordinance. The object was to encourage and facilitate scientific work, and for this purpose the Council is organised in eight divisions, each having its own publication committee. These divisions are:—(1) Astronomy and Geophysics; (2) Chemistry; (3) Physics; (4) Geology and Geography; (5) Botany; (6) Zoology; (7) Medical Sciences; (8) Engineering.

As an hon. member of the Tokyo Chemical Society I have regularly received their monthly journal and frequently have been tantalised by seeing on the cover in English the title of a paper which would have interested me, but being written in Japanese with Chinese characters I have been unable to decipher it. Now, however, the N.R.C.J. is endeavouring on the one hand to encourage authors to write their papers in one of the known European languages, and on the other to make abstracts of those papers which appear in Japanese and print them in either English, French or German. The abstracts are already appearing in the suitable division of the journal of the N.R.C.J., and I am sending you under separate cover for your inspection the first part of the *Journal of Chemistry*.

I also enclose the circular letter issued by the Council from which it will be seen that they are prepared to forward their journals to those institutions which can make use of them and who will state which division they wish. The universities also are very liberal in sending their Memoirs to anyone who desires them. I may instance the Imperial Universities of Tokyo, Kiyoto and Tohoku, Sendai.

I believe only one or two Englishmen are still living who served in Japan in the early days when she was adopting Western sciences. Divers, Ayrton, Perry and Milne are, alas! no more, but what they did for Japan lives after them.—I am, Sir, etc.,

Cardiff R. W. Atkinson

June 23, 1923

[The first part of the *Japanese Journal of Chemistry*, sent by Mr. Atkinson, contains two articles entitled "A Spectroscopic Method of Studying the Formation of Complex Salts in Dilute Solutions" (pp. 1-18) and "On the Chemical Constitution of Squalene" (pp. 19-33), and a number of abstracts covering twenty-two pages. The *Journal* is well printed in clear English and is of convenient size.—Ed.]

LEAD ARSENATE SPRAYS AND BEES

Sir,—I have read with interest Mr. W. F. Reid's letter on the subject of lead arsenate spraying. I am aware that injury to bees has been attributed to the use of this chemical, but have been rather sceptical about it. Has Mr. Reid satisfied himself that the loss in the particular apiary to which he refers was due to the bees absorbing lead arsenate with the nectar from the fruit-blossom? One meets with so many extraordinary superstitions and prejudices among bee-keepers that it is necessary to make quite sure of one's ground. In addition, the reverses of fortune to which bee-keepers have been subjected owing to disease and unfavourable weather have naturally made them suspicious. The loss of bees during the past winter and spring has been exceptionally heavy in this part of the country, owing to the bad weather last summer preventing the accumulation of winter stores, and consequent starvation. The loss, however, is not always attributed to its proper cause. It is, of course, quite undesirable to spray the trees when in bloom. Lead arsenate seems to be the most effective remedy for Codling moth, but the eggs of this moth do not hatch until after the blossom has fallen, and when the apples are setting is the best time.

The problem of rendering the spraying fluid objectionable to bees, if this is really necessary, does not seem to present any particular difficulty. I should suggest the addition of a small quantity of phenol, which is commonly used for subduing bees when examining the hive.

Mr. Reid's ingenious theory to account for the survival of blue-tits in his orchard is admirable, but has he ever offered a dead caterpillar to a small bird? There is something peculiarly unappetising about it. My recollection is of a head held on one side and a beady eye fixed on the inanimate object—and "nothing doing." I might add that I am not interested in the manufacture of insecticides.—I am, Sir, etc., W. S. Gilles

Bocking, Braintree, Essex

June 26

PERSONALIA

Mr. E. C. Williams, M.Sc., Vict., has been appointed to the New Ramsay Memorial Chair of Chemical Engineering at University College, London. Mr. Williams, who graduated in 1914, was a member of the staff of the British Dyestuffs Corporation, and since 1921 has been research chemist to the Joint Research Committee of the University of Leeds and the National Benzol Association.

Dr. R. J. S. McDowall has been appointed to the University Chair of Physiology, tenable at King's College, London.

Dr. H. S. Raper, at present professor of physiology and biochemistry in the University of Leeds, has been appointed Brackenbury Professor of Physiology in the University of Manchester.

Mr. A. B. Weir, B.Sc., A.I.C., has been appointed City Analyst at Aberdeen.

The first award of the Paternò Medal, founded to commemorate the 75th birthday and scientific achievements of the eminent Italian chemist, Senator Prof. E. Paternò, has been made to Dr. F. W. Aston. The award was made during the recent meeting of the International Union of Pure and Applied Chemistry at Cambridge.

Mr. W. Randerson, M.Sc., has been elected to the Albert Kahn Travelling Fellowship for 1923.

An anonymous gift of £20,000 has been made to the Sheffield University for the purpose of establishing an undergraduate scholarship in pure science, and several post-graduate scholarships for research in ferrous and non-ferrous metallurgy.

Sir David O. Masson, K.B.E., D.Sc., F.R.S., professor of chemistry at the University of Melbourne, was entertained to dinner on March 27, by the members of the Victorian Branch of the Australian Chemical Institute, to congratulate him upon receiving the honour of Knighthood. Speeches were made by several of the speakers describing Sir David Masson's work, which includes papers on the ionic theory of Arrhenius, the constitution of the atom, etc.

FORTHCOMING EVENTS

July 2. * The Faraday Society. Ordinary meeting in the Rooms of the Chemical Society, Burlington House, W., at 8 p.m. (1) "On a Relation Between Surface Tension and Density," by A. Ferguson; (2) "Concentration Cells in Methyl Alcohol," by J. Grant and J. R. Partington; (3) "The Law of Definite Proportions in the Light of Modern Research," by U. R. Evans; (4) "Determination of the Density of Charcoal by Displacement of Liquids," by J. B. Firth; (5) "The Formation of Anomalous Liesegang Bands," by F. G. Tryhorn and S. C. Blacktin.

NEWS AND NOTES

CANADA

Prospects for an Artificial Silk Industry

As imports of artificial silk, yarns and thread into Canada reached a value of $2,013,429 ($1,071,255 from the United Kingdom, $397,429 from the United States, and $377,136 from Belgium) in 1922, and purchases of manufactured goods, wholly or mainly of artificial silk, from the United States and the United Kingdom alone reached a total value of nearly $1,000,000, the National Resources Intelligence Bureau of the Department of the Interior has prepared a memorandum on the possibility of establishing the artificial-silk industry in Canada. Should acetate silk be chosen, a special advantage would be the low cost at which synthetic acetic acid can be made by cheap electric power, and a plant situated either in Ontario or in Quebec, where most of the textile plants are situated, would be favourably placed for the domestic market, labour conditions, proximity to raw materials, and also for transport facilities.—(*Ch. Comm. J., June* 15, 1923.)

AUSTRALIA

Metal Production in 1922

The Imperial Mineral Resources Bureau has received from its corresponding member in Australia (the Secretary of the Australian Metal Exchange) the following statistics of the production of refined lead, zinc, silver, copper, tin and iron, and the estimated metal content in ores, concentrates and other partially refined products in 1922 as compared with 1921 :—

			1921		1922
Lead	..	Tons	62,777	..	130,187
Zinc	..	„	21,297	..	159,414
Silver	..	Oz.	5,304,950	..	11,746,295
Copper	..	Tons	18,634	..	11,850
Tin..	..	„	2,990	..	2,657
Pig iron	..	„	352,365	..	83,535

The output of lead, zinc and silver has thus largely increased, but there is a decrease in the production of copper, tin and pig iron, due, in the last case, to the closure of the Newcastle steel works during almost the whole of 1922.

BRITISH INDIA

The New Mysore Distillation and Iron Works

The Mysore Distillation and Iron Works, which commenced operations on January 18, possesses 12 retorts capable of carbonising 240 tons of wood per day; a distillation plant for the recovery and manufacture of methyl alcohol, acetate of lime, and wood tar; and a charcoal blast furnace, with a daily output of 60 tons of charcoal pig-iron, low in phosphorus and sulphur. The wood for the retorts is supplied by the Mysore forest department from 350 square miles of well-wooded State forest, within easy reach of the works by a system of forest railway. Two qualities of wood tar will be recovered :—a "soluble" tar which will make a good disinfectant; and the "settled" tar, which possesses wood-preserving properties. The Mysore Government is considering a large scheme for the antiseptic treatment of railway sleepers with this wood preservative.—(*U.S. Com. Rep., June* 4, 1923.)

Final General Memorandum of the Winter Oilseeds Crop of 1922-23

Estimates based on reports received from provinces containing 98·7 per cent. of the total area under rape and mustard and 99·2 per cent. of the total area under linseed in British India, indicate that the acreage under rape and mustard totals 6,213,000 and under linseed 3,358,000. These figures represent a decrease of 2 per cent. below the areas of rape and mustard estimated at the same time last year, and an increase of 11 per cent. above the areas of linseed estimated in 1921-22. The condition of the crops is reported to be generally good, except in Bengal where the plants were adversely affected through continued absence of rain.—(*Ind. Tr. J., May* 31, 1923.)

UNITED STATES

Peat in 1921 and 1922

There was general depression in the peat industry in the United States during 1921, and many producers closed their works during the whole year. The production decreased by 58 per cent. in quantity, and 72 per cent. in value, to 42,798 short tons valued at $661,613. Despite the fact that the number of producing plants increased by 3 to 21, peat used in the manufacture of fertilisers decreased by 53 per cent. to 29,460 t., and that used in the manufacture of stock food decreased 93 per cent. to 946 t. in quantity. Imports, amounting to 3450 t., showed an increase of 25 per cent., but the price per ton fell from $13·11 to $6·60. Substantial progress was made, however, by the industry in 1922. The number of producing plants increased to 23, and the output increased nearly 100 per cent. in quantity and 52 per cent. in value to 60,680 t. valued at $397,729. Peat used in the manufacture of fertilisers showed an increase of 96 per cent. in quantity, a large increase also being shown by sales of peat used as fuel or as an ingredient of stock food. Imports of peat moss decreased by 1 per cent. to 3394 t., and no exports of peat or peat products were reported.

Fuel Briquets in 1921

Large stocks of coal were on hand at the beginning of the year, and the industrial demand was generally poor, so that the production of fuel briquets fell by 30 per cent. to 398,949 net tons, valued at $3,632,301. This represented a decrease in value of 21 per cent., although the average value per ton increased from \$8·15 to \$9·10. Of the plants that operated, 7 used anthracite culm as the fuel constituent, 2 semi-anthracite, one a mixture of anthracite culm and bituminous slack, one a semibituminous slack, one a mixture of bituminous slack and subbituminous coal, 2 carbon residue from the manufacture of oil gas, and one bituminous coal after low-temperature carbonisation; of the 401,129 tons of raw fuel used, 48 per cent. was anthracite and semi-anthracite, 21 per cent. sub-bituminous coal and gas residue, and the rest bituminous slack and coke. Asphaltic pitch and coal-tar pitch were used as binders for about 61 per cent. of the total output.

Argentojarosite, a New Silver Mineral

In a note in the *Journal* of the Washington Academy of Sciences (Vol. 13, No. 11), W. T. Schaller describes under the above name a new silver mineral from the Titanic Standard Mine at Dividend, Utah. The mineral, which forms small hexagonal scales of a yellow to brown colour and optically is uniaxial and negative, closely resembles jarosite, and has even been mistaken for it. From the average of several analyses its percentage composition is approximately, Ag_2O, 18; Fe_2O_3, 43; SO_3, 28; H_2O, 10; K_2O and PbO traces, corresponding to the formula: $Ag_2O.3Fe_2O_3\ 4SO_3.6H_2O$. Argentojarosite is the first silver mineral recorded which contains oxygen and is apparently sufficiently abundant to be mined as an ore.

GENERAL

Research in the Woollen and Worsted Industries

We have received a list of conditions of award of Research Fellowships and Advanced Scholarships by the British Research Association for the Woollen and Worsted Industries.

The Fellowships are of the annual maximum value of £200 and are granted for one year only, but may be renewed for a second year. It is contemplated that the Fellowship may be held at an educational institution but it is not intended to exclude individuals who dispose of other resources, *e.g.*, in factories. Publication of any research is subject to permission by the Research Association.

The Advancd Scholarships are intended to enable a scholar to carry his education a step further by way of specialisation and not to supplement or substitute county or other scholarships. In awarding these scholarships, the probability that the scholar could eventually undertake research work, would be taken into consideration. Among the subjects suited for textile students in this scheme would be zoology, physics, chemistry, economics, foreign languages, designing, etc. Applications for Fellowships or Advanced Scholarships must be made to the Secretary, Mr. A. Frobisher, B.Sc., at Torridon, Headingly, Leeds.

Radium in Soviet Russia

The Soviet Council of Labour and Defence has enacted that the mining of radium ore and the production of radium are to be controlled by the Supreme Council of National Economy. The Radium Institute of the Academy of Science is to store all the future production and to record the output and supplies on hand in Soviet Russia. It is estimated that the production of platinum in Soviet Russia during the last three months of 1922 was 1924 oz.

Assistance for the Beet Sugar Industry

At present the factories of Home Grown Sugar Limited and the English Beet Sugar Corporation Ltd., are working at capacity and offers for the further production of beet could not be accepted. As these companies have no capital available for building new factories, the British Sugar Beet Growers' Society, in response to inquiries from various sources, has got into touch with persons willing to assist in financing new factories and who can dispose of the necessary technical qualifications and expert staff. As a result of these negotiations, it is stated that the promoters of any scheme in a suitable district can be placed by the Society in touch with people willing to assist a limited number of such schemes subject to certain conditions. Further particulars can be obtained from the British Sugar Beet Growers' Society, 6 Lancaster Place, Wellington Street, Strand, W.C.

"Condensed Smoke"

To many people the idea that "condensed smoke" has a commercial value will seem absurd, yet it is actually in use on a fairly large scale in the United States, especially as a means of flavouring "smoke-cured ham." Smoke from hard-wood is preferred for this purpose, and, in the process used by E. H. Wright—who is the pioneer in this field—about 60 ℔. of smoke is produced from 100 ℔. of wood.

The business, which was founded in 1895, now makes an annual profit of half-a-million dollars. The process is not patented, but kept as a trade secret, and all that is known about it is that the smoke from hard-wood is condensed in an ordinary worm, and is "aged" before placed on the market. In appearance it resembles rye-whisky. No wood alcohol is present, the manufacturer having successfully won a law-suit brought against him by the United States Excise Authorities on this point. The sales are chiefly to farmers and other ham-curers, who are able, by means of "condensed smoke," to impart a desirable flavour to meat which would otherwise lack it. Incidentally, the business is another illustration of the benefits of some form of co-partnership, for, without the enthusiasm and loyalty of the workpeople, which the owner of the works attributes to their having a definite share in the business, it would not have weathered the storms to which it was subjected in its early days.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for June* 21)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia	Tinfoil, glassware	784
"	Hoop iron, mining equipment	785
"	Plant, etc., for pharmaceutical manufacturers	11446/E.D./C.C./2
British India	Glycerin, ferro-silicon (tender)	*
Canada	Hardware	788
"	Leather goods	11428/E.D./M.C./2
"	Smoke-abatement equipment	11427/E.D./E.C./2
Egypt	Builders' tools, pipes	803
France	Metal goods	795
"	Sugar, linseed, copper sulphate, tinplate	796
Netherlands	Sugar	798
Netherland E. Indies	Paint, asbestos sheets, medicines	809
Norway	Sugar	800
Rumania	Spring steel (tender)	10946/F.E./E.C.
"	Foundry coke (tender)	10943/F.E./T.C.
South Africa	Linseed oil, white lead, soap, artificial silk	789

* The Director-General, India Store Department, Branch No. 10, Belvedere Road, S.E. 1.

TARIFF CUSTOMS EXCISE

France.—An import licence is now required for benzol, benzine, toluene and spirits derived from coal tar.

Italy.—Exports of iron ores, except pyrites and scrap of copper, brass, bronze, cast and pig iron and steel are prohibited.

New Zealand.—A new tariff of classification, including copper and iron sheets, tinsmith's materials, etc., has been issued. A primage duty of 1 per cent. *ad valorem* is to be levied on these goods.

Norway.—The duty on sugar has been increased by 10 per cent.

South Africa.—Footware has been excluded from the operation of the Adulterated Leather Act.

Tunis.—Prohibition on the export of ammonium sulphate has been reimposed.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Merchandise Marks Bill

In reply to Lieut.-Col. Hilder, Sir P. Lloyd-Greame said he had received from the Co-operative Congress a resolution objecting to the Merchandise Marks Bill as being "unworkable, vexatious and protectionist in character."—(June 19.)

Applications for Patents

Sir P. Lloyd-Greame, answering Mr. Ede, said that the numbers of complete specifications still under consideration were as follows:—Received within the past 3 months 3157, received from 3 to 6 months ago 1650, from 6 to 9 months ago 600, from 9 to 12 months ago 120, over 1 year ago nil.—(June 19.)

Motor Spirit

Answering Mr. Hardie, Sir P. Lloyd-Greame gave the following figures of the consumption of motor spirit in 1922, the figures for 1914 being given in brackets:—Motor spirit, including benzol, 306,507,753 gallons (141,723,127 galls.), home produced benzol 11,155,756 galls. (17,713,227 galls.). In 1913 the figures were:—Motor spirit 117,524,421 galls., benzol, etc., 12,265,411 galls.—(June 19.)

Cost of Transporting Coal

Col. Ashley, replying to Commander Bellairs, said the average distance over which coal, coke and patent fuel was conveyed by rail in Great Britain in December, 1922, was 42·13 miles at an average rate of 3s. 9d. per ton, the average rate per ton mile being 1·07d.—(June 19.)

The Udi Coalfield (Nigeria)

Mr. Ormsby-Gore, in answer to Mr. A. T. Davies, said that the Udi coalfield was discovered by the Nigerian Government geologist in 1909, but it could not be worked until transport facilities were provided by building a railway of 150 miles from Port Harcourt. That railway reached the coalfield in 1916, and the Government colliery was now producing over 190,000 tons per annum. It was considered inadvisable to admit private enterprise to the field at present because: (1) The Government colliery was already producing more coal than is required in Nigeria and could now considerably increase its output with a corresponding reduction in the pit-head cost, and (2) the labour supply was limited. A private company would experience great difficulties in obtaining sufficient native labour, and competition by private enterprise at present could not fail to increase the cost of labour and therewith the pit-head cost of coal. Increased output and development depended on the possibility of marketing the surplus coal outside Nigeria, and the Nigerian Government would be glad to consider offers by private enterprise to undertake such marketing on an agency or contract basis.—(June 22.)

REPORTS

Report on the Economic and Financial Conditions in Mexico, dated September, 1922.

By N. King, *H.M. Consul-General, Mexico City. Department of Overseas Trade. Pp.* 25. *H.M. Stationery Office,* 1923. *Price* 9*d.*

The economic situation in Mexico still remains unsatisfactory (see *J.*, 1921, 438 R), and trade has been very depressed in sympathy with world conditions. Agricultural enterprise has suffered setbacks from legislation, providing for the partition of large estates into smallholdings; the maize harvest, however, a guide to the economic condition of the country, was good last year.

Data concerning mining are scanty, but the production of a few metals in 1921 (*cf. J.*, 1922, 374 R) was as follows :—Gold, 684,084 fine oz.; silver, 64,474,000 fine oz.; copper, 15,228 tons; lead, 60,513 t.; zinc, 1257 t. The mining industry is improving, and the increased price of silver gives producers more scope for extensions, whilst the Government has recently shown a desire to help the industry which may attract capital. The production of petroleum amounted in 1921 to 30,139,727 t. (24,061,846 t. in 1920); about 70 per cent. of the export is taken by the United States.

In 1920 imports into Mexico were valued at 357,550,442 pesos (1 peso = 2s. 0½d. at par), including chemical and pharmaceutical products, $24,041,724, and minerals, metals, and manufactures thereof, $83,778,834. Of the imports Great Britain supplied about 9 per cent., and the United States about 75 per cent. Exports in the same period amounted to $406,546,900, of which Great Britain took about 3·6, and the United States 88 per cent. British trade in Mexico is handicapped by severe competition from American and German merchants, but there is no reason why this difficulty should not be overcome.

Report on the Commercial, Industrial and Economic Situation in Italy, December, 1922.

By J. H. Henderson *and* C. H. A. Carpenter, *H.M. Commercial Secretaries, Rome. Department of Overseas Trade. Pp.* 73. *H.M. Stationery Office,* 1923. *Price* 2*s.*

Under the new régime in Italy efforts are being made to establish conditions favourable to trade. The worst feature of the outlook is, as in last year, the difficulty in balancing the budget (*cf. J.*, 1922, 223 R).

In 1922 Italian industries were still affected by trade depression, and those dependent on hydro-electric power suffered from a shortage of current owing to the drought of 1921. The total hydro-electric power developed in 1920-21 amounted to 4000 million kw.-hrs. During 1922 a tunnel was opened which enabled the iron ore of the Coque mines to be brought to the electric furnaces of Ansaldo at Aosta; this ore is as good as the best Swedish magnetic ore and will last for 30 years at the present rate of working, *i.e.*, 1000 tons a day. The accession of the mercury mines of Idria has made Italy the largest producer in the world of this metal. Petroleum production is still experimental, the total output for 1921 amounting to 4780 t. The sulphur industry has been almost extinct, but efforts are being made to revive it. The chemical industry in general is in a poor way, though some branches are doing well. Fertilisers have found increased demand, as have also home-produced dyestuffs, though the output of the latter is not yet up to full capacity. A plant has been established at Bordighera for the distillation of essential oils. The glass and pottery industries are suffering, perhaps more than any others, from Czechoslovakian, German and Austrian competition, and some factories have had to close.

Since July 1, 1922, trade returns have been compiled on a new system, and no comparison of the latest figures for imports and exports with those of previous years is possible. In 1921 imports amounted to 15,348·4 million lire, and exports to 7903·2 million lire. Thus exports formed 51·4 per cent. of exports, compared with 43·8 per cent. in 1920. For the first six months of 1922 this figure improved to 54·2 per cent.

The chief imports continue to be wheat, coal, and raw cotton, and the principal semi-manufactured imports are still mineral and other industrial oils, chemicals, and various forms of iron and steel. The main import from Great Britain is coal, 65·4 per cent. of the total import of 1,740,420 t. in 1922 coming from this source, whilst Germany supplied 27·2 per cent. principally on account of reparations. The principal chemicals imported are caustic soda, ammonium sulphate, copper sulphate, sodium sulphide, Glauber's salt, antimony and chromium salts; here, in addition to Great Britain, Belgium, Germany, France, and the United States are in the field, and Italian production meets part of the demand.

Report on the Economic and Financial Conditions in Bulgaria, January 31, 1923.

By D. MacKillop, *H.M. Commercial Secretary, Sofia. Department of Overseas Trade. Pp.* 15. *H.M. Stationery Office,* 1923. *Price* 6*d.*

Bulgaria made steady, and even remarkable progress during 1922. Reduced imports, especially of luxuries and non-productive articles, and increased exports have given the country a trade balance, which, though unfavourable, is comparable with that of an average pre-war year (*cf. J.*, 1922, 335 R). On the other hand, the general uncertainty as to the future in the Near East is unfavourable to trade, as is also the policy of the Bulgarian government, which acts in the interests of the peasant rather than those of the industrialist.

Of the natural resources of the country cereals and tobacco are the most important. The production of rose oil has decreased since 1915. The average annual output before the war was 4000 kg., but in 1921 and 1922 only 1500 kg. and 2000 kg. respectively, were produced. The sugar industry has never been in a strong position, owing to disputes between the beet-growers and sugar-manufacturers, and the 1922 production, 15,000 tons of sugar, was less than half the home demand. The output of coal from the State mines amounted in 1922 to 944,858 t., compared with 871,793 t. in 1921, a year in which 13,968 t. of copper, and 2534 t. of lead were produced. The growth of industry in 1922 was inconsiderable, and is not likely to become important in the near future.

The compilation of trade returns is slow, and the latest complete figures are for 1921. During this year exports were valued at 2,313,827,269 leva (the sterling value of the lev varied in 1922 between 604 and 765) and imports at 2,921,092,269 leva. For the first three months of 1922, however, exports increased and imports decreased, compared with the corresponding period of 1921. Of the imports in 1921 Italy supplied 20·9 per cent; Germany, 18·4 per cent., and Great Britain, 15·3 per cent. In view of the obstacles to British trade, namely, the depreciation of Bulgarian currency, cost of freights and customs dues, the trading position of Great Britain is not unsatisfactory. The British trader does not so willingly risk default in payment as some others and for this reason some Government offers for tenders have been passed by.

REPORT ON THE ECONOMIC, FINANCIAL AND INDUSTRIAL CONDITIONS OF THE UNITED STATES OF AMERICA IN 1922. *By* J. J. BRODERICK, *H.M. Commercial Counsellor, Washington. Department of Overseas Trade. Pp.* 204. *H.M. Stationery Office,* 1923. *Price* 5*s.* 6*d.*

The report opens with an historical survey of American trade conditions during the last century, tracing the transition, through the war, of the United States from a "debtor" country (in the sense of owing large sums as interest on foreign capital, etc.) to a "creditor" country, with exports largely in excess of imports. As a coal producer America holds the foremost position in the world. The output capacity is very elastic, as many small mines produce only when the demand is large. In 1921–22 the output of bituminous coal was 434,279,000 tons, but in 1918–1919, a period of heavy demands, 552,041,000 t. was produced. Coke is now mostly obtained from by-product ovens, and the total output reached high figures between 1916 and 1920. In 1920 51,888,000 t. was produced (60 per cent in by-product ovens), but this figure fell to 25,571,000 t. in 1921 (78 per cent. in by-product ovens). Very little coke is exported, and the production is a rough guide to steel manufacturers' demands. The chief products obtained in 1919 in the manufacture of 25,143,542 t. of by-product coke, were 289,000,000 galls. tar, 544,000,000 lb. ammonium sulphate, 50,000,000 lb. anhydrous ammonia, 415,642,000,000 cb. ft. of gas, and 92,000,000 galls. crude light oil. In 1921 the output of petroleum reached 469,639 thousand barrels (42 galls.) of crude petroleum. The home demand is greater than the home supply, but imports have been unnecessarily large, and big stocks are on hand.

Refined products comprise one of the chief exports of the country. The iron and steel trade experienced in 1922 a revival from the slump which commenced in the autumn, 1920, and steel production increased steadily in May. The copper industry experienced a serious slump when war demands came to an end. An association was formed in 1920 to hold for future export 400 million lb. of copper. The position improved greatly in 1922; most mines are now at work but the demand is still largely met by existing stocks. Spelter production, which had risen from 1150 million lb. in 1914 to 1909 million lb. in 1918, fell by 1921 to 461 million lb. The total zinc production in 1921 was only 200,500 t. (463,377 t. in 1920); but in 1922 there was a slow improvement, and surplus stocks were reduced and prices improved. Exports amounted to 48 million lb. of spelter and zinc sheets in the first seven months of 1922, compared with 4,000,000 lb. for the corresponding period of 1921. The magnesite, manganese, chrome and tungsten industries are in a weak state.

A detailed analysis of the textile, leather, chemical, vegetable oil and some other industries is postponed till the next report. The newly-established dye industry is now in a state of suspense, as a new tariff, although protecting lower grades, leaves competition in the higher grades open to foreign merchants. The chemical export trade has become important, having risen from 22,000,000 dollars in 1914, to 155,000,000 dollars in 1920.

The extensive exploitation of native sulphur beds in Louisiana and Texas has come within this period, and although war conditions were the primary cause of this the output has continued to increase; at present, however, production is in excess of demand. In 1921 1,879,000 t. of sulphur were mined. (For exports of chemicals from U.S.A. in 1922, see *Chem. and Ind.*, 1923, p. 444.)

The total imports of merchandise into the U.S.A. in 1921 were valued at $2,509,000,000, and in the first ten months of 1922, at $2,570,000,000. In the same periods exports were valued at $4,380,000,000, and $3,107,000,000, respectively.

REVIEWS

The Chemistry Tangle Unravelled. *By* F. W. Gray, M.A., D.Sc. *Pp.* $x+148$. *London: Longmans, Green and Co.*, 1923. *Price* 6s.

The title of this book is one that invites challenge. The purpose which the author has in mind involves two distinct factors, and demands in the author two totally distinct types of qualification. The first is that he must be so clear-sighted as to be able to form a bold mental picture of the facts of chemistry, in which every detail is sharply focussed, so that there are no concealed ambiguities even at the back of his mind. The second is that he must have the faculty, possessed in an eminent degree by great evangelists and great music-hall artists, such as Gipsy Smith and Harry Lauder, of transmitting their own clear picture "across the footlights" to the crowds in front. These two faculties were undoubtedly combined in many of the great chemists of earlier days, and in a notable degree by Dalton and by Kekulé, both of whom found in a new nomenclature the means for conveying a new idea in so simple a form that it could be accepted even by chemists of a much smaller average mental calibre. It is possible that Dr. Gray possesses the first of the two essential qualifications, and that he himself has formed a sharply-focussed picture of the facts of chemistry; but his attempt to convey his message to the world at large is so unattractive that it would certainly drive away the "man in the street," although an earnest and diligent student might, perhaps, acquire, after careful study, a working knowledge of the author's point of view.

A nomenclature in which carbon dioxide appears as $C^{+4}\,O_2^{-2}$, and sulphuric acid as

$$\begin{array}{l} \quad\;\; O^{-2} \\ H^{+1}O^{-2}S^{-6}O^{-2}H^{+1} \\ \quad\;\; O^{-2} \end{array}$$

, may possibly be correct; but it will never come into general use, if only because it makes chemistry appear more than ever like a debased form of algebra. The ultimate effect of the author's "unravelling of the chemistry tangle" is to leave so many loose hairs, threads and strands lying about that his equations demand ten times as much thought as those which have, by sheer force of merit, established themselves in universal use amongst chemists; and it is amusing to note that, when he has to deal with a relatively complex equation, such as the reduction of potassium dichromate by sulphurous acid or by sulphuretted hydrogen, the author drops his nomenclature, and falls back on the "unravelled tangle" of the old formulæ and equations, to the immense relief, it must be confessed, of the reader. One of the causes of his lack of success is perhaps that, following Kossel, he bases almost all his formulæ on electron-transference, rather than on electron-sharing; indeed, he does not appear to possess any specific nomenclature for representing the latter, and, therefore very wisely confines himself almost exclusively to inorganic compounds and formulates even the few carbon compounds, which he discusses as united by electrovalencies.

Since his story is not naturally attractive, the author seeks to hold the attention of his readers with the help of italics and heavy type; but these are on the whole rather a drawback than otherwise, as when the author asserts that:—

"*The kernel cation of a complex anion may, then, be of so weak clustering capacity, that it is only by* **multiplexing** *that it can prevail against the competing cation.*"

"*On the other hand, the clustering capacity of the kernel cation may be so strong that it can prevail against several competing cations. We then have the* **reverse of multiplexing** *or what may be called the forming of a* **submultiplex**."

If the above criticisms err on the side of frankness, it may be urged that the author lays himself out to attract such criticisms by the lack of modesty of his title, which is in effect a claim that chemistry in less competent hands has become involved in a tangle, which needed, and has found, a super-chemist to unravel it.

Handbuch der Saccharin Fabrikation. *By* Dr. Oskar Beyer. *Pp.* 143. *Zurich: Rascher and Co.*, 1923. *Price*, .

This book, in the original German, follows an earlier publication by the same author, entitled "Uber die Kontrolle und Herstellung von Saccharin" (1918), and certain portions of the present volume are written as supplements to the first volume. The book is intended particularly to help those who are responsible for the control of works' processes of saccharin manufacture, and in this respect it is most comprehensive. It is clear that the author has carried out the operations which he describes, and he has contrived to publish in a small space a valuable collection of what are really distinct reports covering the whole range of the technical processes involved in the manufacture of saccharin.

The author deals with the synthesis from toluene through the sulphonchloride and sulphonamide to saccharin. Each section (or report) from the first one dealing with the manufacture of chlorsulphonic acid, up to the pressing of the saccharin tablets, is a description of large-scale plant and operations, and the results that can be expected from them. There is a wealth of technical detail of a kind usually difficult to obtain, and the text is freely interspersed with tables, balance sheets of material in and out, diagrammatic sketches and photographs of plant. An inventory is given of the items of plant required for a complete unit, its disposition and the factory buildings necessary to cover the plant. The yields obtained in practice and the amount of materials consumed, including power and other services, are collected in a clear and concise quantity statement, which in turn is developed into an outline cost statement, although no actual prices are entered.

As to the processes described, the author records that from 100 parts of toluene, from 40 to 46 parts of saccharin can be produced, which is a yield figure that manufacturers in this country at any rate would have been glad to reach a year or two ago. In the laboratory, using glass apparatus, is is not difficult to obtain a 60 per cent. yield from toluene, but the elevation of the process, especially the oxidation stage, from the laboratory to the technical scale can provide a good example of the waywardness of things. The oxidation process, the most difficult in the saccharin synthesis, and in which most of the loss occurs, is treated at length, particularly with reference to the use of permanganate as the oxidising agent. Other methods using bichromate and electrolytic oxidation are described, but not in detail. It is interesting to note that the author considers that one of the most important factors for obtaining a successful oxidation is to use only the purest ortho-amide, such as is produced by crystallisation of the crude amide from alcohol. Also, in the process described only 85 to 90 per cent. of the theoretical requirement of permanganate reckoned on the amide is added, and consequently, from 12 to 15 per cent. of the amide is afterwards recovered and returned to the process. This method avoids too energetic an oxidation, which is generally considered to influence the closing of the imido ring unfavourably, but unfortunately, permanganate is not always used as profitably as this work would indicate.

After the oxidation the next most difficult problem is the separation of the ortho and para isomers. The author does not press the separation of the sulphonchlorides, and makes no attempt, by continued freezing, to approach the eutectic mixture of the sulphonchlorides, which contains between 10 and 15 per cent. of the para isomer. The distillation method of separation is mentioned, but is dismissed as irrational. The finished ortho oil contains 20 to 30 per cent. of the para isomer, and is amidated in that state. The various methods for the purification of the amide, namely, the partial precipitation from the sodium salt by acid, crystallisation from water and crystallisation from alcohol are fully treated. All these processes, however, are built upon slight differences in some property such as solubility, and in consequence the most rigid and careful control is required to secure such results as the author indicates.

The book also deals with the physiological action of saccharin and related bodies, new work and various general matters connected with saccharin, its derivatives and other sweetening agents of varying constitution.

L. A. Jordan

X-Rays. *By* G. W. C. Kaye, D.Sc. *Fourth edition. Pp. xxi+320. London: Longmans, Green and Co.,* 1923. *Price* 16*s.*

Les Rayons X. Recuil des Conférences-Rapports de Documentation sur la Physique. *By* M. Maurice de Broglie. *Vol. I. Pp.* 164. *Paris: Albert Blanchard,* 1922. *Price* 13·80 *francs.*

It is some time since the reviewer had the pleasure of reading a scientific treatise so thoroughly informative and yet of such fascinating interest as M. de Broglie's little volume, which forms the first of the series of "Conférences-Rapports" to be published by the *Journal de Physique.* With a boldness which is quite justified by the event, M. de Broglie takes the unusual course of beginning with the explanation and of dealing with the phenomena themselves at a later stage. Both the emission and absorption of X-rays are atomic phenomena and depend on the structure of the atom concerned. Thus a knowledge of the structure of the atom should enable us to predict its behaviour towards X-rays, and conversely a knowledge of the X-ray phenomena throws much new light on the vexed questions of atomic structure. The nuclear theory of the atom first suggested by Sir Ernest Rutherford in 1912 provided a convenient framework into which the new phenomena could be built, and, as developed by Bohr, Sommerfeld, and others, this theory has been found capable of accounting in a most convincing and numerical fashion for the minutest details for X-ray phenomena.

M. de Broglie, then, commences with an excellent account of the atomic theories of Bohr, which he uses as a string on which to thread the varied facts with which he has to deal. He proceeds forthwith to a discussion of the diffraction of X-rays by crystals, and the methods thus provided of determining the wave lengths of X-radiations. An exceptionally illuminating chapter on the absorption of X-rays intervenes, and is followed by a very full account of the various types of X-ray spectra, and the important information to be obtained from them on the subject of atomic structure. The chapter on X-ray spectrometers, which follows, is of great value to anyone who may desire to use this very powerful method of analysis, as the author is an acknowledged expert in the art. The final chapter deals with problems raised by the emission of secondary cathode rays when X-rays are absorbed.

It will be seen from this brief summary that M. de Broglie has marked out for himself a very important, but strictly limited portion of the whole subject. Within these limits he has done admirably, and his account is authoritative and complete. The value of the book to workers in the subject is enhanced by the full and numerous tables which the book contains, and by the excellent bibliographies which are appended to each chapter. M. de Broglie's exceptional clarity both of thought and style, and the skill with which he has evaded mathematical difficulties and complexities allow one to recommend the book with equal confidence not only to experts, but to all who wish to obtain a real understanding of this new and important branch of physics. The book is well got up, and the many plates are excellently reproduced. At the present rate of exchange its price is most moderat.

Dr. Kaye's book on "X-Rays," of which the fourth edition has recently appeared, is too well known to need extensive notice. The fact that new editions are called for with such frequency and regularity shows how indispensable the book is to all X-ray workers in this country. Unlike M. de Broglie, Dr. Kaye attempts to cover the whole subject, including not only the physics, but also the technique and in some measure the practical applications of X-rays. On all matters pertaining to the technique of the production and measurement of X-rays Dr. Kaye is one of our greatest authorities, and his chapters on these subjects will well repay the closest study on the part of those—an ever-increasing number—who find that X-rays are becoming a more and more important tool for their everyday work. The whole book, in fact, is a mine of information for all X-ray workers.

The arrangement of the book seems hardly so satisfactory as its contents. As is perhaps natural in a work, the first edition of which appeared within a year or so of Laue's great discovery, the historical method of development is followed in the main, and the reader lives again through the half-lights and uncertainties of the early stages of the subject, now so happily resolved. Though hints of it are given earlier, it is only in the very last chapters that the reader is initiated into the full solution of the problems presented to him in the previous pages. Dr. Kaye has chosen well from the large amount of new matter which has accumulated, and the new edition is well up-to-date in its facts. The constant additions and revisions have, however, necessarily blurred somewhat the clearness of the presentation of the subject. It would greatly increase the comfort of the reader if Dr. Kaye could find time, in the short interval which may remain before the publication of a fifth edition, to re-write the book from the standpoint of modern theory.

This is, perhaps, too much to ask; and in all other respects the author is to be congratulated on having maintained the high standard of accuracy and information which he himself set in his earlier editions. The reviewer fears he cannot congratulate the publishers on the appearance of this edition, which, in spite of its price, is distinctly inferior to that of its predecessors.

J. A. Crowther

Confectioner's Raw Materials. *By* James Grant, *M.Sc., F.I.C. Pp.* 165. *London: Edward Arnold and Co.,* 1922. *Price* 8*s.* 6*d.*

The object of this little book is to give a brief account of the sources, methods of manufacture, chemical composition and chief uses of the raw materials used by confectioners, and of likely adulterants and the means for detecting them. It is intended mainly for those having but a slender acquaintance with science. The author rightly but optimistically insists that the ideal modern confectioner should, in addition to his practical training, be equipped with a good general knowledge of chemistry, physics, botany and machinery.

A general introduction gives a short but clear explanation of the scope and meaning of chemistry. Subsequent chapters deal with the different classes of substances employed by the confectioner—alcohols and alcoholic beverages, fats, carbohydrates, dried and preserved fruits, essential oils, egg products and colouring matters, organic acids, and the proteins. There are also chapters on baking powders and methods of aeration, the general methods of using the raw materials, and finally some fourteen pages are given up to methods of analysis.

It is obvious that the task of covering so much ground in the limited space available is beset with difficulties, not the least of which is to hit the happy medium between being too popular and too scientific. Assuming a reasonable use of the short but excellent bibliography, the reader will have little cause to complain in this respect. The chapter on analysis is the least satisfactory. If, as it appears, the author assumes that the confectioner is going to carry out the analyses himself, it is far too scrappy and unequal. On the other hand, if the aim is only to give an idea of the general nature of the processes adopted, there is much unnecessary detail. Further, some of the methods suggested, *e.g.*, those for the examination of water, are not only valueless but likely to mislead.

In dealing with some of the manufactured articles more and more accurate information might have been given as to penalties, under various Acts of Parliament, which await the ignorant and the careless, as well as the unscrupulous. It is to be regretted that the author should acquiesce in, if he does not recommend, the use of preservatives, such as boric and salicylic acids and the addition to jams of such stiffening materials as apple pulp.

The book as a whole is clearly and interestingly written, contains for its size much useful information, and should stimulate the practical confectioner to acquire a more scientific interest in and understanding of his work. The illustrations, type and binding are alike excellent.

Cecil H. Cribb

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Prices are practically unaltered in all classes of products, and transactions, except in the really "heavy" chemicals, have been on a small scale. The lateness of the advent of summer weather is undoubtedly delaying purchases by the general public, and this ultimately reacts on every trade—even that in chemicals.

Acetic Acid, 40% tech.	£24 per ton. Still firm, but rather less inquiry.
Acid Hydrochloric	3s. 9d.-5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw.	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Demand steady, export inquiry good.
Arsenic (White)	About £71 per ton.
Bleaching Powder	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Business much below normal.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand.
Copper Sulphate	£27 per ton.
Potash Caustic	£33-£34 per ton. Little moving.
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Potass. Chlorate	3d. per lb. Very dull.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76%	£20-£21 per ton. Steady demand.
Soda Crystals	£5 5s.-£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£26 per ton. Very scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	2¾d.-3d. per lb. Very dull.
Sod. Nitrate refd. 96%	£13 5s.-£13 10s. per ton ex Liverpool. Steady demand.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	£15-£16 per ton carr. paid. Very quiet. Prices unstable.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25-£29 per ton according to quantity.
Carbon Black	1s. 1½d.-1s. 3d. per lb. Ample supplies now coming forward.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb. Firmer on advance in price of Rape Seed Oil.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood distillation products.

Acetate of Lime—	
Brown	£10 15s. per ton d/d. Very scarce. Higher prices would be paid for immediate delivery.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8 5s. to £10 15s. per ton, according to locality of market and type of charcoal.
Iron Liquor	1s. 5d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 8d. ,, ,, 60% O.P.
Solvent	5s. 9d. ,, ,, 40% O.P. Demand increasing.
Wood Tar	£5-£6 10s. per ton, according to grade.
Brown Sugar of Lead	£43 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 4d.-1s. 5d. per lb.
Crude 60's	3s. 4d.-3s. 6d. per gall. Not much business.
Acid Cresylic—97/99	2s. 1d.-2s. 4½d. per gall. More inquiries. Market firmer.
Pale 95%	1s. 11d.-2s. 4d. per gall.
Dark	1s. 11d.-2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	8¾d.-11d. per gall. Supply short.
Unstrained	8¼d.-9d. per gall.

Benzole—	
Crude 65's	1s. 1d.-1s. 1¼d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.
Pure	2s. 1d.-2s. 3d. per gall.
Toluole—90%	1s. 9d.-2s. per gall. Quiet.
Pure	2s.-2s. 5d. per gall. Not much inquiry.
Xylol	2s. 6d.-3s. 3d. per gall., according to quality. Good demand.
Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil Heavy Standard Specification	8d.-10d. per gall. Market steady. Good demand.
Naphtha—	
Crude	9d. per gall.
Solvent 90/160	1s. 7d. per gall. Business slightly better.
Solvent 90/190	1s. 5d.-1s. 7½d. per gall. Market moderately active.
Naphthalene Crude—	
Drained Creosote Salts	£7-£8 per ton. Fair demand. Supply short.
Whizzed or hot pressed	£11-£13 per ton. Plenty of inquiries.
Naphthalene—	
Crystals	£18 10s. per ton.
Flaked	£17 per ton.
Pitch, medium soft	Market firmer. Plenty of inquiries. Prices from 110s.-135s. per ton, according to delivery.
Pyridine—90/140	16s. 6d.-18s. 6d. per gall. Dearer. Demand good.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Business in dyestuffs is moderately good. Depression in the textile trade continues, and until this improves there is not much chance of better business, at least in the home trade. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 6d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 9d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. 6d. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market has been quiet, and prices weaker in consequence of lack of business.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s.-3s. 3d. per lb. The tendency is to ease somewhat, but the strong demand prevents any marked lowering of prices.
Acid, Benzoic	3s 6d. per lb. Still very scarce.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8¾d. per lb., less 5%.
Acid, Gallic	3s. per lb. Steady demand.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d. per lb. for quantity.
Acid, Tannic	3s. 6d. per lb. Firmer tendency.
Acid, Tartaric	1s. 4d. per lb. Demand improved on account of warmer weather.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 6d. per lb. Slow of sale.
Amidopyrin	14s. per lb. Still neglected.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. per oz.
Barbitone	22s. per lb. In very short supply.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Owing to the fluctuation in marks, Hamburg dealers are offering all bromides on this market at very low rates, but British makers maintain their prices without difficulty.
Calcium Lactate	2s. 9d. per lb. for best makes.
Chloral Hydrate	4s. per lb., duty paid.
Chloroform	2s. 2d. per lb. for cwt. lots.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	£90-£92 per ton. Very firm.

Guiacol Carbonate	8s. 6d. per lb.
Hexamine	4s. per lb. down to 3s. 10d. for ½ ton lots. Tendency rather weaker.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Market good with considerable inquiry.
Magnesium Carbonate—	
Light Commercial	£37-£38 per ton net, according to quantity.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	1s. 9d.-2s. per lb. Good demand.
Menthol	40s. per lb. spot.
Methyl Salicylate	2s. 6d. per lb. for carboys. Somewhat weaker in common with other salicylates.
Methyl Sulphonal	15s. per lb.
Paraformaldehyde	3s. 6d. per lb. Weak.
Paraldehyde	1s. 6d. per lb. accepted for large orders. In better supply.
Phenacetin	6s. 6d. per lb. spot value. Very steady.
Phenazone	7s. 6d. per lb. Very firm.
Phenolphthalein	6s. 6d. per lb. now wanted by most holders. Considerable advance in view of shortage.
Potass. Bitartrate— 99/100% (Cream of Tartar)	96s.-98s. per cwt., less 2½%.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. In very strong demand, with no offers from Japan, where there seems to be a great shortage.
Potass. Permanganate	10½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	6s. per lb. still quoted without inquiry.
Salol	2s. 9d. per lb.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 6d. per lb. now wanted by holders. Still in short supply, fresh stocks being quickly absorbed.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality.
Sod. Hyposulphite— Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.-85s. per cwt. Fairly good demand.
Sod. Salicylate	Demand not so good. Powder is slightly weaker at 2s. 7d. per lb., with crystal at 2s. 9d. per lb.
Sod. Sulphite, anhydrous	£27 10s.-£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	15s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.
Thymol	16s. per lb. would now buy finest white crystals. Demand very slow.

TRADE NOTE

Swiss Exports of Coal-tar Dyes

The exports of coal-tar dyes from Switzerland in 1922 totalled 3872·8 metric tons, valued at 55,257,000 francs, compared with 3706·7 tons and 57,676,000 francs in 1921. The following table shows the destination of exports in 1922:—*Aniline and other coal-tar dyes:* United States, 711·3 metric tons; Belgium, 328·2 t.; France, 977·7 t.; Great Britain, 786·6 t. Artificial indigo: China, 3094·8 t.; Japan, 165 t. The decrease in exports to the United States is due to the application of the new Customs Tariff in September. Swiss dye manufacturers are reported to complain of German competition and the effect of German Reparation Dyes on trade.—(*U.S. Comm. Rep., Apr.* 9, 1923.)

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JULY 6, 1923 No. 27

EDITORIAL

SOME vast amount of years ago, ere all our youth had vanished from us, we had an unpleasant habit of trying to confirm or verify many statements of fact repeated from one book to another until they became accepted as matters of gospel. We were reminded of one such search by an obiter dictum of Professor Partington in his article on "Bygone Chemical Technology" in our last week's issue: "The Cassiterides, doubtless the British Isles, appear as sources of tin, first in Herodotus about 550 B.C." We do not doubt that tin exists in the British Isles, and that it has been worked here from a time whereof the memory of man runneth not to the contrary. Nor do we doubt that some writers in bygone days believed the Cassiterides were the British Isles but, when we look to the contemporary writers, Posidonius (as quoted by Strabo and Diodorus Siculus), Mela, Strabo, Cæsar and Pliny, we find no certain reference to Britain, and a good many hints that the Cassiterides were islands off the west coast of Spain. Diodorus says: "Above Lusitania there is much of this metal in the little islands, lying off Iberia in the Ocean, which are therefore called Cassiterides"; and Pliny, in his *Natural History,* states: "Opposite to Celtiberia are a number of islands, which the Greeks called Cassiterides, because of their abundance of tin." The identification of the Cassiterides with Britain or the Scilly Isles is of a later date, and we are not aware that it has any sure foundation, but the statement has been made so often and copied from one book to another that it will now persist nearly for ever. We do not doubt that if careful search were made, some equally well authenticated facts in science could be found which study would show to deserve little acceptance.

* * *

At the Brunner Mond Anniversary Dinner there were some notable speeches; that of Sir J. J. Thomson dealt with education and democracy, not in too serious a fashion, but with that due proportion of the light and heavy which befits an after-dinner speech or an editorial. Let no one despise the editorial; Mr. James Gordon Bennett considered a good editorial to be the highest achivement of the human intellect! Democracy, so far as government is concerned, is a very secure and equitable basis; all are equally compelled to obey the laws, all should share in the responsibility of making them. It is more important to the commonwealth that the laws should be acceptable than that they should be wise; what an infinite number of foolish laws and customs do we cheerfully submit to; we are even proud of them, as of our faults. But democracy as applied to art, to science or to literature is mischievous. For these we do not want a system of education adapted to the great mass of the population; nine-tenths of us are by nature not fitted to become musicians, writers, chemists or even cricketers. It is a very small proportion of mankind which is capable of contributing largely to human knowledge; the highest education is wasted on all except the few and this statement we believe to be true of all classes. On the other hand the exceptional men of genius return a thousand fold the time and trouble spent on their education. One Sir J. J. Thomson, one Dr. Leaf, one Bentley, one Cayley, or one Pasteur is, in the advancement of science, literature or industry, worth more than a very large number of men of rather more than average ability. *Ne e quovis ligno Mercurius fiat*; it is not every piece of wood you can carve into a statue. Progress is very largely due to a small number of men who in genius or character stand head and shoulders above the average. Among such exceptional men we may reckon each in his own sphere those who built up the business we were celebrating, Sir John Brunner and Dr. Ludwig Mond.

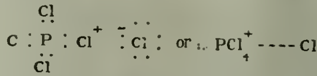
THE STRUCTURE OF THE HALIDES AND OXIDES OF THE 5th, 6th AND 7th GROUPS

BY E. B. R. PRIDEAUX, M.A., D.Sc.

By the earlier electronic theories of valency which contained only the idea of electrovalency, or the passage of an electron from one atom to another, the higher valent compounds of the elements of the 4th to the 7th groups were naturally represented in the same way as the salts of the 1st to the 3rd groups. Thus in such compounds as PCl_5 and $POCl_3$ the phosphorus, as the more electro-positive element, was considered to have lost 5 electrons to the chlorine, etc. Such an idea is not excluded by later theories, and in the compounds of the non-metals with fluorine, oxygen, chlorine which exhibit the maximum typical or group valency the non-metal can be represented as stripping its sheath. Such compounds do not show evidence of electrolytic dissociation, but this might be accounted for, on the one hand, by the difficulty of opening up strong closed fields of force (a difficulty which is already shown by the existence of salts in the non-ionic state in solution), and, on the other hand, by the fact that ionising solvents are decomposed with metathesis of the halogen (hydrolysis, etc.). A more serious difficulty in the way of considering these substances as salts is the fact that in the pure state as liquids they are not associated and have no appreciable conductivity. The two phenomena are connected, since auto-ionisation of a substance appears to depend upon its degree of association. (See Turner, "Molecular Association," p. 102.)

From group IV onwards, then, the compounds of the non-metals with chlorine, etc., are generally considered to be formed mainly by covalent linkages. Simple covalencies in which one electron is contributed by each element suffice for the maximum valency compounds of group IV, but in the succeeding groups, lead to chain or cyclic formulæ, because the maximum members of covalencies required to make up the octets are only 3, 2, 1 in groups V, VI and VII respectively. It may be remarked that the use of the Langmuir equation does not enable us to decide whether a compound is formed with electrovalencies only, or with the maximum possible number of covalencies. For we start with an assumption; if this is to the effect that one of the elements behaves as a metal we do not include it as an "element forming octets," and, *e.g.*, in the case of PCl_5, $2p=5\times8-\{(5\times7)+5\}=0$, but if the element is included as one forming octets, on the assumption that it will tend to take up, rather than lose, electrons, then $2p=6\times8-\{(5\times7)+5\}=8$ and there are 4 duplets.

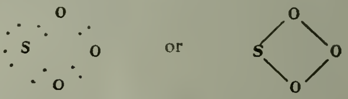
It has been already noticed by Holroyd (*Chem. & Ind.*, 1923, p. 348) that phosphorus pentachloride should have an electrovalency, and accordingly it may be written similarly to NH_4Cl, etc.



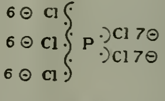
It does not seem very probable, however, that this ionisation will be experimentally verified for the reasons mentioned above. The application of the equation to halogen compounds of groups VI and VII leads to formulæ which appear somewhat improbable. Thus in the case of SF_6 the properties of which are fairly well accounted for by electrovalency alone—$2p=56-48$; $p=4$. There are 4 duplets and two electrovalencies, the formula being—

$$F_4{\equiv}S^{+}_{+}\quad F^-,F^-.$$

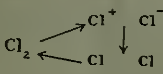
This compound is highly unsymmetrical and might be expected to split off a fluorine molecule rather easily. SO_3 demands 4 duplets, and would be (oxygen octets not shown)



whilst the formula for sulphuric acid, HO—O—S—O—OH, suggests the properties of persulphuric acid. We seem compelled to some disposal of the electrons different from either complete electrovalencies or covalencies. In comparing the possible NCl_5 with the impossible NH_5. Sir J. J. Thomson (*Phil. Mag.*, 41, 243 1921) suggested a structure in which three of the chlorine atoms (considered as cubes with electrons on the corners) are united by an edge to the phosphorus, *i.e.*, by duplets, and the two remaining chlorine atoms are united by a corner, *i.e.*, by half a duplet. These half bonds or partial valencies have been widely employed in the representation of organic compounds (see recent numbers of this *Journal*). In these

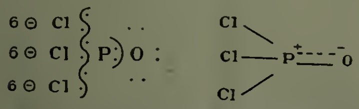


representations it is convenient to divide the electrons belonging originally to each of the elements in order to see at a glance the nature of the charges on each, or the direction of the bipole linkages considered later. Such a formula accounts for the easy detachment, by gaseous dissociation, of two chlorine atoms. When the two chlorines are replaced by oxygen, the $POCl_3$ is not easily dissociable, since the oxygen cannot complete its octets at the moment of dissociation, nor at all except by contact with another atomic oxygen or by an oxidation. Conversely molecular oxygen does not, like chlorine, easily add on to the unsaturated PCl_3, whereas atomic oxygen in the form of ozone does so. The fact that PCl_5 in some reactions is a more powerful chlorinating agent than chlorine itself may perhaps be related to the presence of atomic chlorine having a higher concentration than that derived from the dissociations



The hypothesis of the single shared electron has been applied by the author to many compounds. It is powerfully reinforced by a somewhat similar one suggested by Lowry (*Chem. & Ind.*, 1923, p. 412). "It is a general rule that if one atom shares two electrons with another, but contributes both electrons to the common stock instead of only one, it acquires a positive charge, whilst its neighbour (which has acquired a half-share in two electrons not originally belonging to it) becomes negatively charged." This phenomena was illustrated by amine oxides but is equally applicable to $POCl_3$, and in fine to all the compounds the representation of which meets with the difficulties mentioned above.

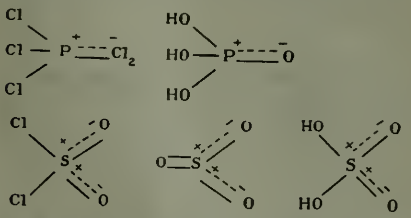
Thus $POCl_3$ may be written :—



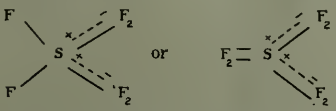
in which, as the dividing lines show, both electrons are contributed by the phosphorus atom, which only has a half share in a pair originally belonging wholly to it and is therefore positively charged, whilst the oxygen atom having a half share in this pair to which it has not contributed is negatively charged. By regarding the PCl_5 molecule in this manner we see that the pair of chlorine atoms are both united to the phosphorus by a single duplet, and thus completely take the place of an oxygen or sulphur atom, and may be replaced by these but not by OH groups. The fifth phosphorus valency is an electrovalency, but is not quite the same as an ordinary electrovalency: no electron has passed across and there is no ionisation possible, except by passing into the tautomeric form of NH_4Cl type. That this mode of union may be a strong one is shown by the fact that PF_5 does not behave as a fluorinating agent.

In the case of all halogen compounds which show the maximum valency of the element, halogen atoms equal in number to the hydrogen (or alkyl) valency in each case and replaceable by OH are shown to be united in a different manner from the remaining halogen atoms which are replaceable by oxygen or sulphur, or are left free in the lower valent compounds.

The formulæ of some compounds of maximum valency will be—



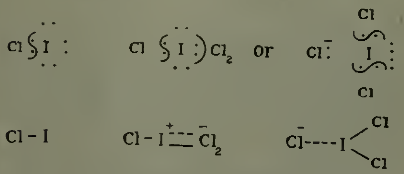
The series SF_6 and its analogues will be represented either by the combination of two fluorines in a covalent manner and the remaining two in a mixed electro- and co-valent manner or by a more symmetrical structure analogous to that of SO_3 :—



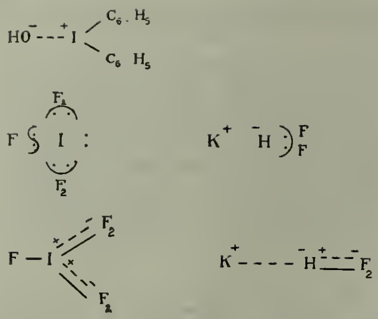
If any fluorine atoms can be replaced by OH, as can happen in TeF_6, they will be the pair united by the two covalencies, as in the case of SO_2Cl_2 and H_2SO_4.

The compounds of the seventh group with one another or with oxygen and hydroxyl cannot be explained by the ordinary kind of covalencies unless chains of atoms are introduced.

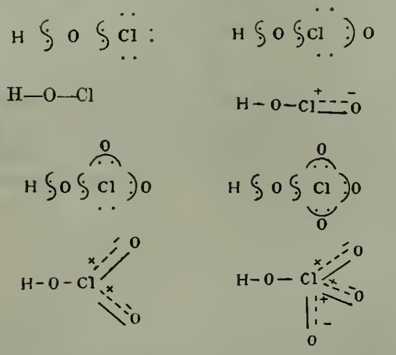
If electrovalency alone is used it is only complete for the heptavalent compounds, otherwise the element is left in a state between the stripped and complemented stable states. The chief types will be represented by



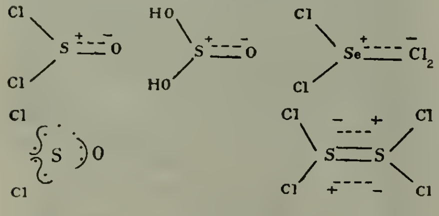
It seems unnecessary to assume that in this compound, which is sometimes ionised (see T. S. Moore, *Chem. & Ind.*, 1923, p. 427), there are any chlorine atoms which are not directly united to iodine. The analogous formula of diphenyl iodonium hydroxide will be



and the fluoride of iodine, the bifluoride of potassium, and the oxyacids of chlorine will be represented by—

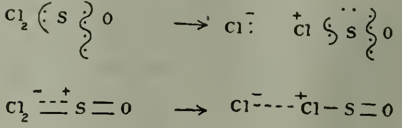


The quadrivalent compounds of the 6th group still have one of these bonds thus :—



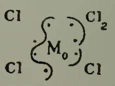
The number of halogen or oxygen ions which can theoretically be given by any of the abovementioned compounds is determined by the requirement that an electro-covalency shall be converted into an electrovalency and a co-valency, thus :—

Therefore RCl_5, as already stated, can give RCl_4^+ and Cl^-, RCl_6 can give RCl_4^{++} and Cl^-, Cl^-. Oxygen from oxychlorides cannot ionise in this sense, but the duplets can shift round from the chlorines to the oxygen and the one electro-covalent bond gives one univalent ion as before :—

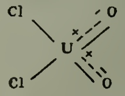


Similarly $SeCl_4$ could theoretically give $SeCl_3^+$ and Cl^- an ionisation which has been already attributed by T. S. Moore (*loc. cit.*) to the unstable SCl_4, which, however, on account of the fact that it can only exist at high chlorine pressures is more likely to have the form given above for $SeCl_4$. With $TeCl_4$ there seems a better probability that this ionisation will be experimentally verified.

Similar considerations apply to the sub-group VIA. Thus WCl_6 can give at the most two chlorine ions and WCl_4 one halogen ion. The constitution of quinquevalent compounds such as $MoCl_5$ would seem to require the hypothesis of the single shared electron first mentioned.

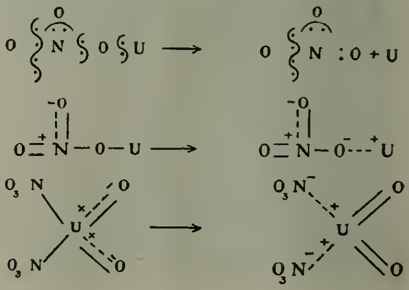


This could give only one halogen ion. The uranyl salts with their formal resemblance to sulphuryl chloride would probably have a similar formula in the case of the chloride



But the nitrate when ionised would pass over into a structure in which all the oxygen is combined by covalencies. The NO_3 group according to the above hypotheses is written :—

Non-ionised Ionised



The other method of writing this compound with the correct number of duplets is

$$O_3N{-}O{-}\underset{\cdot\cdot}{\overset{\cdot\cdot}{U}}{-}O{-}NO_3$$

Numerous other examples which might have been given show that the electro-covalent bond abolishes a good many incongruities and awkward formulæ. In the lower valent compounds of the 4th and 5th groups, however, great difficulties are encountered. It is hoped that these will form the subject of a further communication.

University College, Nottingham
April 30, 1923

THE BANQUET OF MESSRS. BRUNNER MOND & CO., LTD.

The Chairman and Directors of Messrs. Brunner, Mond and Co., Limited, gave a dinner at the Hotel Victoria, London, on Friday, the 29th June, to celebrate the Fiftieth Anniversary of the founding of their works at Winnington. The occasion was a great one, and the banquet was worthy of it. Mr. Roscoe Brunner presided; with the exception of Mr. Robert Mond, whose health did not permit him to be present, all the directors were present. The guests included Sir William Alexander, Dr. Walter Leaf, Sir J. J. Thomson, the Vice-Chancellor of the University of Cambridge, the Rt. Hon. J. R. Clynes, Sir Edward Brotherton, Bt., Sir Max Muspratt, Bt., Sir William Pope, Sir John Russell, Sir Richard Threlfall, Sir George Beilby, Dr. E. F. Armstrong, Sir Robert Robertson, Sir Frank Heath, Sir Arthur Colefax, and many other men distinguished in the profession of chemistry, in the manufacture of chemicals, in politics, in the law, and in a variety of other walks of life. The great majority of the guests met, not only a number of old friends whom they saw fairly frequently, but many others whom they had not seen for a long time; probably this was due to the fact that the guests were drawn from many sections of society.

Sir William Alexander proposed the toast of Messrs. Brunner, Mond and Co., Ltd. After alluding to soda as the badge or coat-of-arms of domestic cleanliness, he contrasted the histories of two British discoveries, the Ammonia Soda process of Dyar and Hemming of 1838, and the making of mauve by Perkin in 1856. The founders of the company had worthy successors, and the chairman, with ever-increasing success, was upholding the traditions of enterprise, courage and service. The firm were pioneers in the reduction of hours of work, in granting holidays with double pay, housing for workers, pensions for the feeble and disabled, and long-service awards for merit. Mr. Roscoe Brunner, in his reply, referred to Dr. Leaf as a representative of the bankers who, in the early days of the firm, had rendered such valuable assistance; he mentioned the lofty standards of integrity, determination, and scientific knowledge which characterised those who founded the firm, and rightly claimed that the firm had succeeded and continued to succeed because of such standards. Sir Alfred Mond who also responded to the toast gave some interesting sketches of the early history of the works, and his informal and pleasant reminiscences helped his audience to appreciate the many difficulties and the genius of the two men who overcame them.

Sir John Brunner proposed Science in very appropriate terms, alloying the soft metal of research with that due proportion of harder business instinct which is necessary to the permanence of prosperity. On behalf of Science Sir J. J. Thomson replied, reminding us that it was not everyone who could be trained to the highest pitch in science, that in America the very best athletes were trained with incessant care, the next best being sent out to applaud. Mr. Gerald Balfour proposed the Guests; Dr. Walter Leaf and the Vice-Chancellor of the University of Cambridge responded. Sir Max Muspratt, in proposing the health of the chairman, spoke of the days when both of them, *arcades ambo*, were lively boys, all unconscious of their fate.

Mr. Roscoe Brunner replied, and so concluded a delightful evening. Without a single exception the speakers spoke out, in both senses; they were easily heard and they spoke in a natural and sincere manner the thoughts which occurred to them on this historic occasion. There were no purple patches of sonorous eloquence, but all the speeches had a true ring about them, they were of the right length, in the right key, and made by men, to whom, both on account of the good sense they spoke, and their own intrinsic merits, all were glad to listen.

THE WOOD-PULP INDUSTRY IN QUEBEC

The Agent-General for Quebec informs us that a new groundwood pulp mill, with a daily capacity of 100 tons, will be built this summer at Sillery, near the City of Quebec. The plans include provisions for expanding the plant to produce sulphite pulp and newsprint paper whenever it is desired to make the necessary additions. The mill will be exceptionally well located for shipping facilities, having both rail and water connexions and favourable arrangements for its supply of pulpwood.

THE MECHANISMS OF OXIDATION IN THE LIVING BODY*

By Prof. F. GOWLAND HOPKINS, F.R.S.

The explanation of how the oxidation of foodstuffs occurs in the living body is a fundamental problem of biochemistry, for such foodstuffs are stable in the presence of molecular oxygen at the temperature and hydrogen-ion concentration proper to living tissues. It is probable that carbohydrates, fats and proteins may undergo preliminary non-oxidative changes yielding autoxidisable derivatives, but no autoxidisable product has yet been isolated which can be shown to represent a stage in the line of change. Special catalytic agents or systems maintained as constant constituents in the living cell control the processes involved.

The evidence for the "oxidase" theory of catalysis is mainly indirect, and although such systems may exist in many plant and animal cells, yet no organic peroxidase has been isolated, nor has the chemical nature of any naturally occurring peroxidase been made clear. It appears, however, that oxidative systems of this type would seem to play only a subsidiary part in metabolism. Much progress has followed upon the work of Bach and others, who have shown that many biological oxidations occur in aqueous solution in the complete absence of free oxygen so long as a reducing substance is also present. In fact, living tissues contain enzymes which actively catalyse those simultaneous and correlated processes of oxidation and reduction which may occur anaerobically in aqueous solutions. According to the established nomenclature, a substance which under these conditions suffers reduction, is called the hydrogen acceptor, the substances simultaneously oxidised being called the oxygen acceptor.

Experimental studies of anaerobic oxidations by Thunberg and others have shown that many substances, some of which occur in metabolism, are freely oxidised anaerobically by tissue catalysts when a suitable hydrogen acceptor is provided. Although reducible substances naturally present in the living cell may act as hydrogen acceptors, so that biological oxidations may occur anaerobically, the fact of most significance is that molecular oxygen can itself act as the hydrogen acceptor, so that tissue catalysts capable of controlling oxidations of the type under discussion can function in true respiratory processes. Many substances, including fatty acids, certain amino-acids, purins, etc., are oxidised *in vitro* under the influence of catalysts derived from living tissues, and this, under suitable conditions, *either* anaerobically or aerobically. The catalysts involved may display specificity in relation to the substrate, but there is no reason to suppose that in the case of a given substrate the aerobic and anaerobic oxidations are controlled by different catalysts.

According to Bach the essential happening is the uptake of hydroxyl groups by one acceptor and of hydrogen atoms by the second acceptor, and a modification of the water molecules leading to the formation of a peroxide hydrate and oxygen perhydride. But H. Wieland holds that many typical biological oxidations are in reality processes of dehydrogenation, the catalytic action of the enzymes concerned consisting in activating certain hydrogen atoms in the substrate, so that these are readily taken up by appropriate acceptors. In cases such as the oxidation of succinic acid to fumaric acid, this view permits of a simple application. In other cases the participation of a hydrate is proven or must be assumed.

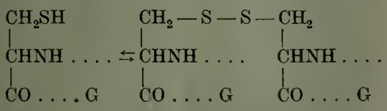
Whatever the precise nature of the chemical mechanism of these anaerobic or aerobic oxidations, it is sure that many biological events belong to the class represented. On the other hand, the catalytic systems responsible for their control in the living cell must be diverse. Apart from the marked specificity of these in relation with the substrates oxidised, they cannot be uniform even in type, because such great differences are found in their relative stability. Some seem to belong to the fluid phases of the cell-structure and display the characters of enzymes in ordinary colloid solution. Others are more closely associated with the solid structures in the cell, perhaps because special surfaces form an essential part of the catalytic system. Of these some, like that which is responsible for the oxidation of succinic acid, are relatively stable; whilst others, such as that which induces the oxidation of citric acid, are so unstable that brief exposure of a tissue to alcohol or acetone removes their activity. In the living cell there are certainly agents able to constitute oxidising systems which are not only more stable than those hitherto mentioned, but which, being also thermostable, are not to be classed as enzymic systems in any accepted sense of the word; thus, certain compounds of iron undoubtedly exercise a direct catalytic function in cell oxidations; respiration, indeed, has been defined as "a surface phenomenon catalysed by iron" (Warburg).

Of great significance are disulphide and thiol groups, which in the cell suffer reversible oxidations and reduction. In 1907 A. Heffter pointed out that the reducing powers of such substances as cystein, thioglycollic acid and thiolactic acid resemble those displayed by animal tissues. He showed that the tissues probably contain some constituent carrying an active sulphydryl group, and suggested that this might play a part in the respiratory changes of the cell. In 1918 O. Meyerhof showed that the thioglycollic and thiolactic acids acted as oxygen carriers, and when added to acetone yeast restored to the dead cells a part of their "respiratory" activity, which had previously been removed by washing with water.

---

*Report presented at the Meeting of the International Union of Pure and Applied Chemistry at Cambridge.

In 1921 Hopkins (*Bioch. J.*, 15, 286) separated from yeast and from mammalian muscle and liver a substance which he called *glutathione*. It is present in most, if not all, actively living tissues, and is a dipeptide in which glutamic acid is condensed with cystein, or (in the oxidised form) with cystine. The reduced form of glutathione (corresponding to cystein) and the oxidised form (corresponding to cystine) may be represented as follows, G standing for a glutamic acid nucleus attached *either* to the amine or carboxyl groups of the cystein (or cystine) :—



$$\begin{array}{lll} CH_2SH & CH_2-S-S- & CH_2 \\ | & | & | \\ CHNH\ldots\ldots \leftrightarrows & CHNH\ldots\ldots & CHNH\ldots\ldots \\ | & | & | \\ CO\ldots\ldots G & CO\ldots\ldots G & CO\ldots\ldots G \end{array}$$

In the case of the dipeptide, the disulphide as well as the thiol form is freely soluble in the tissue fluids, whereas cystine is not. Hence the capacity of glutathione to suffer reversible oxidations and reductions offers a more efficient chemical mechanism than the system cystine $\rightleftarrows$ cystein. In the tissues, the equilibrium is usually such that the greater part of the substrate is in the reduced form, and its thiol group contributes to the reducing power exhibited by fresh tissues. To appraise properly the significance of the substance in respiratory processes, it should be remembered that in the living tissues the thiol group of glutathione is autoxidisable, though the dipeptide structure as a whole is stable. On the other hand, the disulphide form which arises on oxidation is under similar conditions freely reducible to the thiol form by factors present in the tissues. For example, if fresh muscular tissue is thoroughly extracted with cold water, its previous ability to reduce methylene blue is lost, the treatment having removed the glutathione. If now the washed tissue be suspended anaerobically in a suitable fluid to which the *oxidised* (—S—S—) form of glutathione has been added, even in very low concentration (*e.g.*, M/500), the system thus established freely reduces methylene blue ; this is because the washed tissue first reduces the dipeptide to its thiol (—SH) form. It thus appears that the reducing potential of the extracted tissue-residue is not sufficient to reduce methylene blue or only sufficient to reduce it with a velocity too slow for observation. Yet this same tissue can reduce with much greater velocity the disulphide group of glutathione, which, in its thiol form, at once reduces the dye.

Taking the simplest view, we may look upon the —S—S— group as an intermediate hydrogen acceptor which facilitates the transport of hydrogen from oxidisable substances in the tissue to the methylene blue. The properties of glutathione fit with special readiness into the conceptions of Wieland ; it appears as a catalyst of hydrogen transport. However, the hydrogen transported may really arise, as in Bach's view, from molecules of water, whilst the tissue-constituents act as oxygen acceptors.

Glutathione functions in a similar way in aerobic conditions, when molecular oxygen becomes the final oxygen acceptor. A tissue when extracted with water as described above, and suspended in a fluid at the p_H proper to the living tissue, takes up atmospheric oxygen extremely slowly, if at all. If, however, a little glutathione, in its oxidised form, be added, oxygen is rapidly absorbed until a definite maximal uptake is reached corresponding with the complete oxidation of those tissue constituents which share in the process. A certain concentration of the thiol form is produced and maintained during the course of the oxygen uptake. The glutathione molecule itself suffers no oxidation under such circumstances, except the reversible one relating to the sulphur groups. Even a tenfold increase in its concentration, whilst increasing the velocity of the reaction, is without effect upon the amount of oxygen finally taken up. This is proportionate to the amount of tissue and to that alone.

These considerations by no means give a complete picture of the chemical events involved. Even the process of autoxidation of the —SH group (in other compounds as well as in glutathione) requires detailed study. Dixon and Tunnicliffe have shown, for instance, that the reduction of methylene blue by reduced glutathione, cystein or thioglycollic acid involves an autocatalytic reaction, and have established the remarkable fact that the active agent is in each case the disulphide form itself of the compound concerned, R—S—S—R. Indeed, all the disulphides studied catalyse reductions due to the sulphydryl compounds. Moreover, all the disulphide compounds investigated catalyse the oxidation of the sulphydryl compounds by atmospheric oxygen.

Glutathione by no means catalyses all the oxidations which occur in the living cell ; it is not a co-enzyme in the stricter sense of the word and seems not connected with the oxidations due to the enzymes and other unstable catalytic systems referred to. Its function, nevertheless, is to control no small part of the total respiratory events. It is not yet certain what, as a whole, the tissue constituents may be which remain in the water-extracted tissue and while in this residual tissue are oxidised in the presence, but *not* in the absence, of the thio-compound. Unsaturated fatty acids form, however, one known material of which the oxidation is actively catalysed by glutathione, and this as simple glycerol esters or when present in lipoids of the lecithin type. It is noteworthy that such fatty acids are oxidised by glutathione in the absence of tissue elements ; but only when the sulphydryl form is present from the first. A system composed of the glycerol ester of linoleic acid suspended as an emulsion in Ringer's fluid at p_H 6 and shaken with air takes up oxygen very slowly. The addition of a minute quantity of glutathione in its reduced (—SH) form greatly accelerates this uptake, and the amount of oxygen absorbed when equilibrium is reached is greatly in excess of that required to oxidise the —SH group itself. The addition of the oxidised (—S—S—) form of the dipeptide induces, on the other hand, no acceleration of the oxidation of linoleic acid in the absence of a tissue preparation. The reason is that the fatty acid does not primarily reduce the disulphide group. It is clear, therefore, that for the simple autoxidising system (fatty acid *plus* glutathione) the conception of hydrogen transport as outlined above cannot hold.

Otto Meyerhof has studied this matter, using, however, thioglycollic acid (not a natural cell constituent) as the active sulphur compound. He assumes that during the autoxidation of the thiol group peroxide formation occurs, and that this is followed by a transfer of the oxygen molecule as a whole to the unsaturated fatty acid or other organic molecule (M); somewhat as follows :—

(*a*) 
$$2RSH+O_2\rightarrow R.S.\,.H\diagup\overset{O—O}{}\diagdown H\,.\,.\,S.R$$

(*b*) 
$$R.S.H.\diagup\overset{O—O}{}\diagdown H.\,.S.H.+M\rightarrow 2RSH+MO_2$$

On this view the reduced form of glutathione might represent in the living cell a peroxide-forming factor of the kind postulated in the theory of oxidases. Whether the view proves to be justified or not, oxidation in such a system as that constituted by an unsaturated fat and the thiol form of glutathione, without a tissue preparation, never proceeds to completion. In the presence of the tissue residue, the system becomes different : since the tissue contains factors capable of actively reducing the disulphide group, a concentration of the thiol group is continuously maintained. The amount of fat oxidised is limited only by the amount of these reducing factors supplied to the system. These facts illustrate the importance of coupled or consecutive reactions in the chemical organisation of the living cell.

This view of the mechanism of oxidation of unsaturated fatty acids in the presence of the thiol group raises afresh the general question as to whether or not peroxides formed during autoxidations play any more than a subsidiary part in cell oxidations. Belief in their importance is justified by the fact that oxidations by peroxide of hydrogen are especially apt to resemble biological oxidations. But it is difficult to demonstrate directly the occurrence of peroxides in the cell or during oxidations induced experimentally with cell catalysts. The existence in the cell of the agent catalase which must inhibit the formation of any appreciable concentration of hydrogen peroxide seems to suggest that in biological oxidations the influence of peroxides is at most of secondary importance.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinions by his contributors, but it must be understood that he does not necessarily agree with them.

Is the Annual Meeting Too Formal ?

seems to be the question asked by the Editor last week, and in supplying the answer to his own question (as editors so often do), he suggests that perhaps we might have a supplementary annual meeting immediately preceding the Annual Dinner. I believe the Editor is as near being wrong in this suggestion as an editor ever can be. In my view the President's Address could and should be discussed the same day as it is delivered, preferably immediately after lunch, when the company has had time to think over what has been said. It should even be possible to supply prints of the address at the close of its delivery. The Annual Dinner should surely be held during the week when the Society is holding its meetings. Indeed, I took it that the Dinner in Trinity College Hall, Cambridge, which we so enjoyed a fortnight ago, was the official Dinner of the Society. If we are to have another, I hope it will be one in which all the scientific societies will join to make it a really representative gathering. Surely we can combine in our social functions, even if there is nothing else in which we are prepared to act together.

About Two Hundred

distinguished people sat down to dinner last Friday to commemorate the fiftieth anniversary of the founding of the Winnington Works of Brunner Mond and Co., Ltd. The eminence of the visitors fortunately did not overshadow the "family" character of the proceedings. I enjoyed hearing the Chairman, Mr. Roscoe Brunner, and then Sir John Brunner and Sir Alfred Mond referring modestly, and yet with real and proper pride, to the work which their fathers had done. Sir Joseph Thomson, in replying to the toast of "Science," seemed to me to have combined successfully a certain amount of worldly wisdom with his great scientific knowledge. He told us that chemical industry could not live on an influx of money but that it wanted a vitamin. I gathered that this is the product the Universities are turning out for us at the moment. His reminiscences of America were most interesting, and the moral was that industry must maintain the Universities in order that they may turn out the men required by industry. The Vice-Chancellor of Cambridge University, in replying for the visitors, confessed that he had a hectic week with the visit of the Society to Cambridge. The speech of Sir William Alexander deserves a fuller comment than I can make this week;

it was something rather more than a mere after-dinner speech.

The Annual Reports

of the Chief Inspectors under the Alkali etc. Works Acts have just been published. There is something about these reports which distinguishes them from the ordinary run of Blue Books and White Papers. Notwithstanding the fact that the reports are sometimes badly arranged, and, as in the case of the Scottish report this time, almost telegraphic in their literary style, yet they are always very welcome. If any other department of the Government were to produce such reports they would be received very differently. The truth of the matter, as I have only discovered recently, lies in the fact that the Alkali Inspectors are a body of men who have very gradually won the respect of chemical industrialists. They started under a severe handicap: no works manager welcomes the idea of a visit from a Government official. Soon their tactfulness removed any idea of Government "interference" with business, and latterly their usefulness to industry as well as to the State has become recognised. So much is this the case that when a year or so ago the question of raising the fees under the Act arose, from which fees the staff are paid, chemical industrialists agreed at once to pay 50 per cent. more than they were paying.

The Alkali Inspectors

point out that although there has been a distinct improvement in some sections of the heavy chemical trade, what may be called normal conditions have not yet been re-established. They also refer to the introduction of new methods of manufacture, on the one hand, as a hopeful sign of the future of the country, and, on the other, a call to increased vigilance on the part of the Alkali Inspectors. I rather agree with them when they express surprise that any chemical manufacturer can be so unfamiliar with the operations registrable under the Act as to lay themselves open to penalties for carrying on such operations. Yet so it is, and six works in the year under review were discovered doing so. All the way through the reports there are instances where manufacturers for their own (and the surrounding neighbourhood's) good have been gently coerced into getting rid of their noxious fumes instead of letting them loose on an unsuspecting public: "Two works have given considerable trouble, but a steady application of pressure has secured better working and greater attention to detail. . . . It is confidently anticipated that the improvement is of a permanent character." In another case: "The District Inspector had occasion to complain. . . . As a result a considerable improvement has been effected." In trying to convey the spirit of the reports I ought not to omit to mention the valuable statistics, a noteworthy feature.

SOCIETY OF CHEMICAL INDUSTRY

LIST OF MEMBERS ELECTED

June 21, 1923

Coles, Alfred B., Technical College, Workington, Principal.
Cruikshank, Samuel G., c/o Tasmanian Cement, Ltd., Railton, Tasmania, Chemist.
Dent, James H., 25, Dover Street, Crumpsall, Manchester, Chemist.
Dow, Eric, 9, Park Quadrant, Glasgow, W., Research Chemist.
Feeny, Howard R. J., 2, Mannering Road, Sefton Park, Liverpool, Technical Chemist.
Frame, Archibald W., 662, Fillmore Avenue, Buffalo, N.Y., U.S.A., Chemist.
Furusaki, Hidejiro, 3570, Agariyashiki, Mejiro, Tokyo-fu, Japan, Engineering Chemist.
Hill, R. Ashton, 4, Cloud View Cottages, Timbersbrook, Congleton, Cheshire, Chemist.
Hutchinson, Dr. Henry B., The Distillers' Co., Research Laboratory, Hammersmith Distillery, Hammersmith, London, W. 6, Technical Bacteriologist.
Jeacock, Arthur G., "Ombersley," Moughland Lane, Runcorn, Analytical Chemist.
Karavaeff, Nicolas M., 8, Campden Grove, London, W., Engineer-Chemist.
Lawrence, William J., 13, Bryant Street, Rockdale, Sydney, Australia, Chemist.
Lee, Frederick C., 5, Bower Street, Oldham, Manufacturing and Analytical Chemist.
Macarthur, Hector, 23, Langside Road, Newlands, Glasgow, Assistant Works Manager.
McEvoy, Fred, 161, North Road, St. Helens, Analytical Chemist.
Ohfuka, Mitsuzo, Bei Dr. C. Tobias, 16, Hähnel Strasse, Dresden, Germany.
Rao, K. Umanatha, c/o The Mysore Distillation and Iron Works, Bhadravati, Shimoga District, Mysore State, India, Chemist.
Rawlinson, Herbert, 21, Clarendon Road, Garston, Liverpool, Chemist.
Turner, Sydney L., 26, Aston Street, Oxford, Chemist.
Veillon, Dr. Louis, c/o The Graesser-Monsanto Chemical Works, Ltd., Ruabon, N. Wales, Director.
Wainwright, Frank, "Heathside," Heath Road, Runcorn, Analytical Chemist.
Whiston, John R. H., Artillery College, Red Barracks, Woolwich, London, S.E. 18, Lecturer in Chemistry.
Willcox, Cyril M., 4, Worple Avenue, Wimbledon, London, S.W. 19, Student.

DEATHS

Calm, Dr. Charles E. (elected 1902), California Club, Los Angeles, Cal., U.S.A., Chemical Manufacturer. On 22 May, 1923.
Clemes, J. H. (elected 1893), 111, Mount Wise, Newquay, Cornwall. On 8 May, 1923.
Esilman, Alexander (elected 1884), of 38, Norwood Avenue, Southport, Lancs., Analytical Chemist. On 13 April, 1923.
Klipstein, Ernest C. (elected 1902), of 93, Prospect Street, East Orange, N.J., U.S.A. On 29 April, 1923.
Scard, Frederic I. (elected 1917), c/o West India Committee, 14, Trinity Square, London, E.C. 3, Consulting Chemist. On 22 June, 1923.
Storie, Geo. Bright (elected 1914), of Hotel Atlantic, Beach and Rockland Roads, Sea Point, Cape Town. On 21 May, 1923. Works Manager.
Wilkinson, Herbert T. (elected 1916), 17, Grosvenor Gardens, Westminster, London, S.W. 1, Engineer. On 7 May, 1923.

THE FARADAY SOCIETY

Five papers were read at the meeting held on July 2 :—(1) " Determination of the Density of Charcoal by Displacement of Liquids," by Dr. J. B. Firth. Investigation showed that the value obtained for the density of the charcoal increases with the time of contact between the liquid and the charcoal. The final density value varies with different liquids. The rate of change in the density value and the final density will be determined by the rate of sorption and sorptive capacity respectively. Cude and Hullet concluded that sorption forces exert only a very minor influence. The author, however, found that the density of each variety of charcoal is higher in benzene than in water which, compared with chloroform and alcohol, again gives the lowest value. Capillarity is an important factor, but the author believes that an additional force of a chemical nature which is responsible for sorption phenomena also operates. A further factor that must also influence the final result is the compressibility of the liquids.

(2) " Concentration Cells in Methyl Alcohol," by J. Grant and Prof. J. R. Partington. The paper consists of a re-examination of Wilson's work on the E.M.F. of concentration cells formed from solutions of silver nitrate in methyl and ethyl alcohol, compared with the E.M.F.'s calculated from Nernst's formula. The authors' results are in satisfactory agreement with Nernst's equation and show that the discordant results of Wilson must have been due to experimental errors.

(3) " The Formation of Anomalous Liesegang Bands," by F. G. Tryhorn and S. C. Blacktin. The authors adduce two examples of the production of these bands in addition to the case of lead chromate in agar gels first noticed by Hatschek, and show that the substances formed in these three reactions crystallise from the respective gels more readily in the light than in the dark. This effect is put forward to explain the formation of anomalous bands in these instances, and a tentative suggestion of the mechanism of the process is advanced.

(4) " On the Relation between Surface Tension and Density," by Dr. A. Ferguson. The paper consists of a mathematical investigation of the exactness and physical meaning of the relation between surface tension and density, designed to determine the connexion of the constant C in Macleod's formula $\gamma = C(\rho_l - \rho_v)^4$, with other physical constants.

(5) " The Law of Definite Proportions in the Light of Modern Research," by U. R. Evans, M.A. The author points out that many solid solutions met with in alloys show a maximum melting-point (*i.e.*, a maximum thermal stability) at a composition indicated by a simple atomic formula. It is usual to describe this number of the series as an " inter-metallic compound," and to record it as the parent of the series, but where there is a maximum hardness, *i.e.*, a maximum mechanical stability, at a composition indicated by a simple atomic formula, or where there is an abrupt change of chemical behaviour, it is not customary to apply the word compound. The use of the word is clearly one of convenience, and the compound is often merely a member of a continuous series of solid solutions, but possessing greater stability than other members. The fact that the maximum stability usually occurs at a composition expressible by a simple formula, is often capable of physical explanation. Many oxides of metals which possess more than one valency have variable composition. The decomposition pressure varies greatly with the oxygen content, thus distinguishing these solid solutions from mechanical mixtures. There is a continuous series of iron oxygen crystals varying in composition between Fe_3O_4 and Fe_2O_3 and homogeneous bodies of variable oxygen content occur along with oxides of platinum, iridium, nickel, molybdenum, tungsten, and possibly silver, lead and thallium. Similar series can be traced among various chlorides, bromides and sulphides.

ACADÉMIE DES SCIENCES

At the meeting held on June 11, Monsieur Lemoine presented a paper in which he showed that on cultivating *B. subtilis* in an infusion of hay, the acid formed was intermediate between glucose and acetone.

The influence of neutral salts on silica gels was discussed by Monsieur Urbain ; Prof. C. Moureu gave a list of radioactive springs ; and Dr. Roux communicated a note by MM. Levaditi and Nicolan on the immunity of body tissues.

PERSONALIA

The following names are included in the Prime Minister's List of Honours, conferred on the occasion of the King's birthday :—*Baronet*, Sir A. J. Dorman, K.B.E., J.P. *Order of the British Empire, Commander of the Civil Division*, E. T. Neathercoat, president of the Pharmaceutical Society. *Imperial Service Order*, Mr. T. J. Cheater, B.Sc., Superintendent Chemist, Customs House Laboratory.

The following officers have been elected by the National Academy of Sciences : President, Prof. A. A. Michelson ; vice-president, Dr. J. C. Merriam ; secretary, Dr. David White ; foreign secretary, Prof. R. A. Millikan ; and treasurer, Dr. F. L. Ransome, and Professors D. L. Webster and R. C. Tolman as council members.

Dr. V. F. Hess has resigned his post as chief physicist to the U.S. Radium Corporation in order to take up the professorship of experimental physics at the University of Graz, in Austria.

CORRESPONDENCE

BIOCHEMICAL ACTION OF POLARISED LIGHT

Sir,—In tropical and sub-tropical countries there is a deep-rooted belief in the poisonous character of meat, and especially fish, that has been exposed to strong moonlight. South African fishermen, Italians and Malays mostly will not go out fishing at full moon, nor will housewives knowingly buy fish caught beneath or exposed to lunar radiation. Many of our transport-riders will not sleep where the full moon can shine on their faces. Perhaps this may seem to many readers like "lunacy" in more than one sense. Some years ago I wrote a letter to *Nature* on this subject and detailed certain experiments I had made. I received personal replies from England, Canada and Australia giving apparently well-authenticated cases of actual poisoning from eating "moon-struck" fish or flesh (the Canadian and English correspondents had served as sailors in tropical waters). So far as I know no scientific worker took up the matter.

Now that the Biochemical Society is in being, and that your *Journal* numbers the members of that society among its readers, I thought it might be of interest to bring the matter up again in the hope that someone better qualified than myself might investigate it. My own experiments were necessarily very crude and ill-fitted to deal with such problems as fermentation and putrefaction, yet they showed results of some promise.

In searching for any possible explanation of the alleged action of moonlight, I recalled the well-known fact that moonlight, like almost all reflected light, is more or less polarised. In order, then, to obtain artificial "moonlight" I took a 1000 candle-power electric lamp and reflected a portion of its rays from a pile of glass plates. Some perfectly fresh fish were taken and split lengthways so as to get two portions as nearly alike as possible. One half of each fish was placed directly under the lamp and about one foot away from it, the other was a little further off, and only the reflected light was allowed to reach it. The whole arrangement was enclosed in a cool, dark chamber for from twelve to twenty-four hours. The sole criterion of any change that I could make use of was the effect on my own nose, but it was quite sufficient. The specimen exposed to the reflected light was invariably in the condition known as "stinking," the other piece being far less affected. I also attempted experiments on the growth of seeds and of moulds, but they were inconclusive.

It seems almost impossible that the possible chemical or biochemical action of polarised light has hitherto not been investigated, but I have never been able to find any reference to the matter in the records I have been able to examine. Since ordinary light has such marked effects, it seems *a priori* reasonable to suppose that polarised light might have even stronger powers as a directional agent for certain changes. If that be so, the poisonous effects of easily decomposed matter exposed to moon-rays is explainable.

Another matter mentioned by my correspondents was "moon-blindness"; a person with apparently normal eyesight by day becoming totally blind in moonlight. I have never seen any other mention of this phenomenon.—I am, Sir, etc., E. G. Bryant

Prieska, S. Africa

THE FORMULA OF CARBON MONOXIDE

Sir,—The formula of carbon monoxide presents a good deal of interest from the point of view of the octet theory.

The formula $:\mathrm{C}\overset{\textstyle :}{\underset{\textstyle :}{:}}\mathrm{O}:$ allows us to represent both atoms as surrounded by an octet, and receives support from thermochemical data.

v. Weinberg (*Ber.*, 1920, 1352) has pointed out the remarkable fact that the heat of combustion of a ketone, such as $CH_3.CH_2.CO.CH_2.CH_3$ equals the heat of combustion of CO + the heat of combustion of the hydrocarbon—in this case $CH_3.CH_2.CH_2.CH_3$—which would be formed by the combination of the remaining parts of the ketone molecule.

In the example chosen we can imagine the two carbon-carbon bonds between the carbonyl group and the neighbouring carbon atoms to be overcome, thus conferring the energy of two carbon-carbon bonds on the system, and then we can imagine the two ethyl groups uniting, which would involve the loss of the energy of one carbon-carbon bond. If the carbon monoxide formed had the constitution represented by the formula $C = O$, the net result would be that we conferred the energy of a carbon-carbon bond on the system, and we should expect the heat of combustion of the two new compounds to be greater than that of the ketone by an amount equal to the value of one carbon-carbon bond.

Since the new compounds have the same heat of combustion as the ketone, we must conclude, as v. Weinberg does, that more valency is exercised on the oxygen by the carbon in carbon monoxide than in the ketone, and further that this increase in energy of combination is equal to that of a C-C bond.

This increased energy of combination of carbon and oxygen finds expression in the formula $:\mathrm{C}\overset{\textstyle :}{\underset{\textstyle :}{:}}\mathrm{O}:$ v. Weinberg shows, further, that $Q_{C=O}$ (*i.e.*, the energy of combination of carbon and oxygen in the ketones) is equal to Q_{C-O-C} (*i.e.*, the energy of combination of carbon and oxygen in the ethers) (*cf.*, Hückel, *Ber.*, 1922, 2841).

In spite of the great affinity of carbon for oxygen, carbon monoxide is stable in the air at ordinary temperatures, whereas nitric oxide is spontaneously oxidised, although nitrogen has not much affinity for oxygen. It is not possible to represent nitric oxide with a complete octet round each atom if we use the electrons of the outer shells only. We can only write

$\cdot\mathrm{N}\vdots\mathrm{O}\vdots$ This may be connected with the tendency to oxidise.—I am, Sir, etc.,

NEWS AND NOTES

"Van't Hoff Fund."

The Faraday Society announces that application for grants from the above Fund must be made before November 1, 1923, by registered post to: Het Bestuur der Koninklyke Akademie van Wetenschappen; bestemd voor de Commissie van het "Van't Hoff-fonds," Trippenhuis, Kloveniers-burgwal, te Amsterdam, with a detailed account of the proposed use of the grant, and of the reasons on which the candidate grounds his claim. The grants are made to investigators in the fields of pure and applied chemistry. The amount available for 1924 is about 1400 Dutch florins.

The Arsenic Industry in Canada

The Canadian production of arsenic declined from 4,918,000 lb. ($447,848) in 1920, to 2,982,000 lb. ($269,300 in 1921). The production in 1920 included 3,662,000 lb. of white arsenic, the remainder of the output being obtained from arsenical concentrates. Important deposits of arsenic occur in the Kingston district, some containing as much as 12 per cent. of arsenic. Arsenic is also a constituent of silver-cobalt ores obtained at Cobalt, Ontario, large quantities being recovered in the silver refineries. Recently, the manufacture of insecticides was commenced at Deloro, Ontario.—(*Cham. Comm. J., June* 23, 1923.)

The Japanese Camphor and Celluloid Industries

It is reported from Yokohama that the Japanese camphor market has begun to revive in consequence of orders received from Europe and the United States. There is also a certain improvement in the celluloid industry, and camphor manufacturers in Japan and Formosa are now supplying the home trade. Since 1916, when the record production of 6,517,232 kin of crude camphor and 11,010,059 kin of camphor oil was obtained, the output has decreased gradually until in 1921 it was 2,535,047 kin and 7,224,600 kin, respectively. Exports have also decreased, falling from 6,014,200 kin in 1916, to 982,700 kin in 1921.—(*Cham. Comm. J., June* 23, 1923.)

PARLIAMENTARY NEWS

HOUSE OF COMMONS

The Alcohol Industry

Replying to Mr. Hardie, Capt. D. King said available information indicated that there were 125 distilleries producing alcohol solely for use as a beverage, 14 producing it for use as a beverage and in industry and 3 for industrial purposes only.

Sir W. Joynson-Hicks, in a written answer to Viscount Curzon, gave the following figures of consumption of spirits during the year ended March 31, 1923:—*Home-made spirits*: retained for consumption, 12,858,660 gallons; exported (excluding Irish Free State exports *via* Great Britain), 5,848,787 galls.; exported as medical preparations, 167,960 galls.; used for ships' stores, etc., 320,638 galls.; used in arts and manufactures, 597,669 galls; methylated, 6,458,695 galls.; allowed as deficiencies, 3,706,703 galls.; distilled in England, 6,564,824 galls., in Scotland 27,095,609 galls., and in Northern Ireland 2,476,985 galls. *Foreign spirits*: retained for consumption, 2,299,620 galls.—(June 26.)

Exports of Coal

Sir P. Lloyd-Greame, answering Mr. Hardie, gave the following figures of exports of coal from the United Kingdom and of imports of coal into Great Britain and the Dominions during 1922, the figures for 1913 being given in brackets:—*Exports of Coal from the United Kingdom*: Italy, 6,341,743 tons (9,647,161 t.); Spain, 1,711,021 t. (2,534,131 t.); Germany, 8,345,606 t. (8,952,328 t.); France, 13,579,417 t. (12,775,909 t.); India, 999,159 t. (179,192 t.); Denmark, 2,866,233 t. (3,034,240 t.); Sweden, 2,522,820 t. (4,563,076 t.); Algeria, 1,032,282 t. (1,281,664 t.). *Shipments of Coal from Great Britain to Ireland*: 4,062,748 t. (4,667,548 t.). *Imports of Coal into Great Britain and the Dominions*: Great Britain, 113 t. (7226 t.); British India, 1,191,966 t. (622,659 t.); Dominion of Canada, 11,622,344 t. (16,251,744 t.); Commonwealth of Australia, 15,213 t.* (4849 t.); Dominion of New Zealand, 501,478 t. (468,940 t.); Union of South Africa, 4358 t. (51,526 t.); Newfoundland, 223,300 t.† (289,451 t.).—(June 26.)

* Year ended June, 1921, later figures not being available.

† Year ended June.

Consumption of Boiler Fuel in Collieries

Replying to Lord Cavendish-Bentinck, Lieut.-Col. Lane-Fox said that 16·25 million tons of coal was consumed under colliery boilers at coal mines in Great Britain during 1922. The percentage of output thus consumed was 3·3 in Durham, 5·9 in the Eastern districts, 9·5 in Lancashire and 9·7 in Scotland. The reasons for this disparity were discussed in the final report of the Mining Sub-Committee of the Coal Conservation Committee (Cd. 9084). Allowance had to be made in any such comparison for the difference in the calorific value of the coal used for steam raising in the different districts.—(June 26.)

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for June* 28)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W.1) from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Leather	835
,,	Rubber goods, bronze and copper tubes ..	836
Australia	Steel	11541/E.D./E.P.
Belgium ..	Pharmaceutical specialities	814
British India	Steel rails (tender) ..	*
Egypt ..	Hides (tender)	**
Italy ..	Shellac, gum arabic, medicinal herbs and plants	818
Japan ..	Steel	10966/F.E./E.C./2
Norway ..	Sugar	822
Poland ..	Caustic soda, perfumery, ethereal oils ..	823
Spain ..	Chemicals, fertilisers ..	824
,, ..	Rubber sheeting, surgical and rubber goods	825
Spain and Portugal	Chemicals	826
Tripolitania	Sugar	830
United States	Fertilisers, glassware ..	19858/F.W./M.C./2.

* Director-General, The East India Railway Co., 73-76 King William Street, E.C. 4.

** Muh. 1923/64/1 Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, S.W.1.

TARIFF CUSTOMS EXCISE

France.—Anthraquinone is now admitted duty-free.

Malta.—Amendments in the customs tariff affect petrol and refined and raw sugar.

New Zealand.—The prohibition of the exportation of silver has been revoked.

Rumania.—New export duties have been applied to caustic soda, tinplate, iron sheets, zinc dross and casein. Copper sulphate is exempted from import commission tax.

San Salvador.—A duty of 5 per cent. has been imposed on exports of sugar.

Sweden.—The sugar import monopoly has been withdrawn and all restrictions removed.

REPORTS

FORTIETH REPORT OF THE COMPTROLLER-GENERAL OF PATENTS, DESIGNS AND TRADEMARKS, 1922. *Pp.* 20. *H.M. Stationery Office,* 1923. *Price* 6*d.*

That the business transacted by the Patent Office is gradually approaching a more normal level may be judged by the slight increase (compared with previous years) in the number of applications for patents in 1922, viz., from 35,132 to 35,494; of provisional specifications from 24,674 to 25,862; complete specifications from 19,159 to 19,060, and of sealed patents from 17,697 to 17,336 (*cf. J.*, 1922, 296 R).

A small increase was shown in the number of applications for trademarks (11,620 as against 11,168), but the number registered under Part A decreased from 6787 to 6443. The number of letters and correspondence forms despatched was 275,000, and the number of parcels of publications 113,000, compared with 265,000 and 112,000, respectively, in 1921. There was a slight decrease in the sales of the various publications of the Patent Office.

Hearings upon oppositions to the grant of patents numbered 83, as compared with 35 in 1921, and there were 12 appeals to the Law Officer. Hearings fixed under Sections 7 and 8 of the Acts numbered 3384, but 1712 were either abandoned or withdrawn. In five of the 1762 cases outside appeals were made to the Law Officer. Altogether 135,785 readers used the Library (129,975 in 1921), and the number of works in the library increased to 61,106, the approximate number of volumes, excluding duplicates, being 194,697.

Receipts from patents fees were £413,378, from designs fees £10,373, and from trademarks fees £46,045, compared with £445,947, £9648 and £47,803 respectively in the previous year. Receipts fell by £32,367 to £493,133. Expenditure totalled £419,059, leaving a surplus of £74,073.

REPORT ON THE ECONOMIC AND FINANCIAL CONDITIONS IN GERMANY TO MARCH, 1923. *By* J. W. F. THELWALL, *H.M. Commercial Secretary, Berlin, and* C. J. KAVANAGH, *Commercial Secretary, Cologne. Pp.* 157. *Department of Overseas Trade. H.M. Stationery Office. Price* 4*s.*

The outstanding features of Germany's position in 1922 were, as in the immediately preceding years, inflation and reparations, and they have become more important with the lapse of time. Extreme caution has to be observed in coming to a conclusion on the actual position of the country as results of trading are almost completely disguised by inflation.

Trade in 1922 was much below pre-war level, but it must be remembered that the pre-war frontiers were wider than the present ones, and also that reparations do not figure in trade returns. Exports, 21,560,244 metric tons in

1922, amounted to 29 per cent. of the pre-war figure and imports, 45,871,043 t., to 62 per cent. In the latter part of the year exports declined and imports increased. Coal, coke, and briquettes imported in 1922 amounted to 10,914,000 t., exports to 6,115,000 t.; imports of iron ore were 9,276,000 t., exports, 117,900 t.; iron imports 774,300 t., exports 199,800 t.; cement imports, 122,500 t., exports, 350,200 t. The policy of merchants as to prices has been very erratic and though this is comprehensible when applied to inland sales, owing to fluctuations of currency, it is less so where exports are concerned, as merchants are encouraged to quote in a stable currency. Complaints from buyers have come from all over the world; these appear to be due chiefly to an excess of orders leading to neglect of contracts and scamping of work. It is considered that in any case satisfactory conditions cannot be established until control of exports is abandoned. Important commercial treaties were entered into in 1922 with Finland, Lettland, Russia, and Czechoslovakia.

The occupation of the Ruhr area last January created a new situation with regard to Germany's coal supply. Of her pre-war coalfields Germany has lost Lorraine and 75·4 per cent. of the Upper Silesian area, whilst the Ruhr and Aix-la-Chapelle fields may be drawn upon only at the discretion of the occupying Powers; the annual supply of the country is only about 18,576,000 t. compared with 190,109,000 t. in 1913, whereas in 1922 about 163,621,000 t. was required. The sinking of new shafts, a work neglected since the beginning of the war, is becoming a necessity, but the cost presents an obstacle; levies on coal and coke have been suggested as sources of revenue for the purpose. Lignite has been produced in increasing quantities and in 1922 the output was 137,207,000 t. The relatively high cost of transport prevents the use of lignite, however, except near its source. Instead of being the largest European exporter of iron and steel, Germany has now become the largest importer, with serious effects upon State finance. The industry itself is working at full pressure, but only as the result of inflation. Germany is no longer self-contained as regards the raw materials of the iron industry; home production of ore in 1922 was about 5,000,000 t., and imports about 11,000,000 t. The pig-iron output in 1922 was about 9,000,000 t.; the demand has been relieved to some extent by the extensive use of scrap iron and steel. The steel trade has been busy, with demands far in excess of supply, and the 1922 output is estimated at 9,000,000 t.

In an appendix devoted to potash it is pointed out that of the world's consumption in 1922, 1,600,000 t., Germany supplied 1,300,000 t.; thus the supposition that the loss of Alsace would break the German monopoly does not appear to have been fulfilled.

REVIEWS

Market Milk. *By* E. Kelly *and* C. E. Clement. *Pp. xvii*+445. *New York: John Wiley and Sons; London: Chapman & Hall, Ltd.*, 1923. *Price* 19*s*.

"Market Milk" is a term in general use in America to distinguish milk sold ultimately by retail in its liquid state, from the equally large volume of milk which is ultimately marketed as cheese, butter, and other manufactured goods. One of the authors is described as a "Market Milk Specialist" in the United States Department of Agriculture, and the other as in Charge of the Market Milk Investigations of that Department. Of their qualifications, therefore, to write of the production and distribution of milk in their own country, there can be no doubt. The book will be studied eagerly in Great Britain because certain sections of the milk industry are disposed to adopt certain American practices, and because there appears to be in Whitehall and elsewhere an organised attempt to accelerate this tendency. The circulation of this book may well have a contrary effect, although its authors seem well satisfied with the way that the trade in market milk is carried out and regulated in the United States. A study of this book, however, must make clear to those who did not realise the fact before that our insular problem is very different from that which confronted the great cities of the States. Distances are so much less here. As the President of the forthcoming World's Dairy Congress said to the writer, what we call "long-distance milk" would be regarded as "short-distance milk" in America, and we ought to be able largely to dispense with pasteurisation, which is becoming universal in America.

The book is not written for chemists, but no chemist who is connected with the milk industry should fail to study it. In studying its interesting statistics, one has constantly to bear in mind that the American gallon is only 0·83 of an imperial gallon. There is no aspect of the market-milk industry that is not dealt with, and dealt with at length, so one need not reproduce the Table of Contents, minutely subdivided as is the way with American books. The amount of supervision to which American traders submit, and the readiness with which they produce detailed profit and loss accounts to these statistical officers will occasion surprise to British readers, but in some respects Whitehall might take a lesson from Washington. For example, the authors say that in planning a grading system, it is desirable to have only a very few grades, and they suggest three. Now grading is of long-standing in America. Here we have just started with five official grades, exclusive of ordinary milk, which is still the staple article of the trade.

The section on the cost of milk production is particularly interesting just now to us in Great

Britain, and not less interesting because it gives costs of milk produced under conditions differing widely from our own. Very briefly the authors discuss the question: "Can production cost govern selling price?" and their conclusions can be commended to the consideration of everyone in the industry. One section may do mischief if it falls into the hands of ignorant people anxious to fasten American standards upon us. In some States of the Union it is an offence to sell milk containing less than 3·5 per cent of fat, and this is stated in the book. The application of such an ordinance in Great Britain would hold half the milk off the market from March to August inclusive. Reformers of a certain type do not think of these things.

There are very few misprints or statements of fact to which exception can be taken. In a table on page 16, 24·68 per cent. of milk sugar in condensed milk appears to be a misprint for 14·68 per cent. On page 52 one reads that the freezing point of milk is usually from 29° to 31° F. On page 130 it is correctly stated that the freezing point of milk is practically constant at -0·55° C. On page 19 it is stated that scientific opinion is generally to the effect that heated milk is uninjured in its nutritive properties. One could cite many authorities against this dictum. Finally, on page 252 the estimate for a 500 gallon plant ($4000-6000) must be too low, or that for a 1000 gallon plant ($15,000-25,000) too high.

G. Cecil Jones

Anorganische Chemie. Ein Lehrbuch zum Weiterstudium und zum Handgebranch. *By Prof.* Fritz Ephraim. *Second edition, revised. Pp. viii+742. Dresden and Leipzig: Theodor Steinkopff,* 1923. *Price, paper,* 8*s.* 6*d., bound,* 10*s.* 8½*d.*

The utility of this comprehensive text-book of inorganic chemistry may be gathered from the fact that only a few months after publication a second edition has been called for (*cf. J.*, 1922, 407 R). Opportunity has accordingly been taken to add accounts of recent work, such as that of Bohr on the rare earths, and to enlarge the subject index. By the use of concise, clear language the author manages to cover a very wide range of subjects and although omissions are inevitable in a work of this kind, nothing of real importance has been neglected. The book is primarily of interest to advanced students, but it should prove stimulating reading for everyone who has more than a slight knowledge of chemistry.

Mr. C. H. MacDowell, president of the Armour Fertiliser Works, Chicago, has been awarded the United States Service Medal for his work as Head of the Chemical Branch of the War Industries Board during the war.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech...	£24 per ton. Still firm, but rather less inquiry.
Acid Hydrochloric ..	.. 3s. 9d.-5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw. ..	.. £23 per ton.
Acid Sulphuric ..	.. Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical ..	.. £6 10s. per ton.
Ammonia Alkali ..	.. £7 12s. 6d.-£8 per ton. Demand steady, export inquiry good.
Arsenic (White) ..	.. About £71 per ton.
Bleaching Powder ..	.. Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Business much below normal.
Bisulphite of Lime ..	.. £7 per ton, packages extra.
Borax, Commercial—	
Crystal ..	.. £27 per ton.
Powder ..	.. £28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride ..	.. £5 17s. 6d. per ton d/d. In slightly better demand.
Copper Sulphate ..	.. £27 per ton.
Potash Caustic ..	.. £33-£34 per ton. Little moving.
Potass. Bichromate ..	.. 5¾d.-6d. per lb. d/d.
Potass. Chlorate ..	.. 3d. per lb. Very dull.
Salammoniac ..	.. £32 per ton d/d.
Salt Cake ..	.. Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76% ..	.. £20-£21 per ton. Steady demand.
Soda Crystals ..	.. £5 5s.-£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98% ..	.. £26 per ton. Very scarce for spot delivery.
Sod. Bicarbonate ..	.. £10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62% ..	.. £19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate ..	.. 2¾d.-3d. per lb. Very dull.
Sod. Nitrate refd. 96%..	.. £13 5s.-£13 10s. per ton ex Liverpool. Steady demand.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	£15-£16 per ton carr. paid. Very quiet. Prices unstable.

Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25-£29 per ton according to quantity.
Carbon Black	1s. 1½d.-1s. 3d. per lb. Ample supplies now coming forward.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood distillation products.

Acetate of Lime—	
Brown	£11 10s.-£11 5s. per ton. Dearer. Good steady demand.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8 5s. to £10 15s. per ton, according to locality of market and type of charcoal.
Iron Liquor	1s. 5d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	1s. 3d. „ „ 14/15° Tw.
Wood Creosote	2s. 7d. „ „ Unrefined.
Wood Naphtha—	
Miscible	6s. 8d. „ „ 60% O.P. Market quiet.
Solvent	5s. 9d.-6s. per gall. 40% O.P. Demand increasing.
Wood Tar	£5-£6 10s. per ton, according to grade.
Brown Sugar of Lead	£42-£43 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 4d.-1s. 5d. per lb.
Crude 60's	3s. 4d.-3s. 6d. per gall. Numerous inquiries.
Acid Cresylic—97/99	2s. 1d.-2s. 4½d. per gall. Steady demand.
Pale 95%	1s. 10d.-2s. 4d. per gall.
Dark	1s. 10d.-2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	8¾d.-11d. per gall. Supply short. Plenty of inquiries.
Unstrained	8¼d.-9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1¼d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.
Pure	2s. 1d.-2s. 2d. per gall.
Toluole—90%	1s. 9d.-2s. per gall. Quiet.
Pure	2s.-2s. 5d. per gall. Not much inquiry.
Xylol	2s. 6d.-3s. 3d. per gall., according to quality. Good demand.
Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil	8d.-9½d. per gall. Market steady. Good demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.-9½d. per gall.
Solvent 90/160	1s. 6½d.-1s. 7d. per gall. Business quiet.
Solvent 90/190	1s. 5d.-1s. 7½d. per gall. Market moderately active.
Naphthalene Crude—	
Drained Creosote Salts	£7-£8 per ton. Fair demand. Supply short.
Whizzed or hot pressed	£11-£13 per ton. Few inquiries.
Naphthalene—	
Crystals	£18 10s. per ton.
Flaked	£17 per ton.
Pitch, medium soft	Market quiet. Prices from 110s.-135s. per ton, according to delivery.
Pyridine—90/140	17s.-18s. per gall. Demand good.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Business in dyestuffs is moderately good. Depression in the textile trade continues, and until this improves there is not much chance of better business, at least in the home trade. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 6d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Dinitrobenzene	11d.-1s. per lb. naked at works.

Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 9d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. 6d. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market remains very dull and stocks are slowly accumulating.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s.-3s. 3d. per lb. Market steady but quiet.
Acid, Benzoic	2s. 6d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8¾d. per lb., less 5%.
Acid, Gallic	3s. per lb. Down to 2s. 11d. for large quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 3d. per lb. Orders falling off.
Acid, Tannic	3s. 6d. per lb. Firmer tendency.
Acid, Tartaric	1s. 4d. per lb. Demand improved on account of warmer weather.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 6d. per lb. Complete lack of demand.
Amidopyrin	14s. per lb. Still neglected.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. per oz. More active.
Barbitone	21s. per lb. Less inquiry.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Unchanged. Continent still offering at low prices.
Calcium Lactate	2s. 6d. per lb. for best makes. Foreign makes of inferior quality still being offered.
Chloral Hydrate	3s. 8d.-4s. per lb., duty paid.
Chloroform	2s. 2d. per lb. for cwt. lots.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	£90-£92 per ton. Very firm.
Guiacol Carbonate	8s. 6d. per lb. Neglected.
Hexamine	3s. 7d. - 3s. 10d. per lb. Tendency rather weaker.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots.
Magnesium Carbonate—	
Light Commercial	£37-£38 per ton net, according to quantity.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	1s. 9d.-2s. per lb. Good demand.
Menthol	40s. per lb. spot.
Methyl Salicylate	2s. 4d.-2s. 5d. per lb. for carboys. Somewhat weaker.
Methyl Sulphonal	15s. per lb.
Morphine	Makers have advanced all prices. Alkaloid—Cryst. 10s. 11d., Precip. 10s. 8d., Acetate 8s. 6d., Hydrochlor. 8s. 6d., Sulphate 8s. 6d. per oz.
Paraformaldehyde	3s. 9d. per lb. Lifeless.
Paraldehyde	1s. 6d. per lb. accepted for large orders. In better supply.
Phenacetin	6s. 6d. per lb. More active than other pharmaceuticals.
Phenazone	7s. 6d. per lb. More active than other pharmaceuticals.
Phenolphthalein	6s. 6d. per lb still quoted, but demand slow.
Potass. Bitartrate—99/100% (Cream of Tartar)	96s.-98s. per cwt., less 2½%.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d.-15s. 11d. per lb. In very strong demand.
Potass. Permanganate	10½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	6s. per lb. Very firm.
Salol	2s. 9d. per lb.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 6d. per lb. Slow of sale.
Sod. Citrate	2s. 2d. per lb. for U.S.P. quality.
Sod. Hyposulphite—Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.-85s. per cwt. Fairly good demand.
Sod. Salicylate	Powder 2s. 7d. per lb., and Crystal at 2s. 9d. per lb. In steady demand for small lots.
Sod. Sulphite, anhydrous	£27 10s.-£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.

Thymol	.. Better inquiry. 15s. 6d. per lb. for cwt. lots of natural recryst. The synthetic product is being offered at 14s. 6d. per lb. for cwt. lots.

TRADE NOTES

The Japanese Fertiliser Trade

During 1922 the Japanese fertiliser trade recovered considerably from the previous year's depression, and imports increased nearly 42,000 tons in quantity and 15,000,000 yen in value (yen = 2s. 0½d.). Exports increased in value by 538,325 yen to 859,665 yen. The agricultural demand, however, is still low. The following statistics show the values and quantities of fertilisers imported during 1921 and 1922:—

	1922 tons	1922 Yen	1921 tons	1921 Yen
Ammonium sulphate..	92,284	12,742,145	78,596	11.006,010
Nitrate of soda	52,447	6,540,094	18,057	2,601,093
Sulphate of potash ..	7,431	1.003,560	1,194	224.044
Bean cake	1,093,250	89.375,154	1,196,841	85,793,475
Rape seed cake ..	70,519	5,350,549	46,190	3.169,110
Cotton-seed cake ..	34,719	2,978,912	58,024	4,387,443
Oil cake, other ..	10,704	817,718	15,180	961.235
Fish guano	22,308	3,043,951	1,256	193,879
Phosphate rock ..	282,827	8,983,554	210,586	8,884,692
Bone dust	40,429	3,789,465	29,099	2.375.700
Animal bones	20,403	1.964,500	30,618	2,302.187
All other manures ..	—	881,150	—	899.624

It is stated by the Department of Overseas Trade, which has furnished these figures, that imports of ammonium sulphate from the United States and from Great Britain stand in the proportion of roughly 8 to 1. Exports of phosphatic fertilisers continued to decrease, but exports of oil cake rose considerably. Production costs hamper the Japanese manufacturers in competing in foreign markets.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JULY 13, 1923 No. 28

EDITORIAL

IN our issue of June 29 we suggested that the Presidential Address of this year was of such importance that a discussion of it was very desirable, that no adequate opportunity for discussing it existed at the Annual Meeting, and that it might be worth while to have a full discussion of it prior to the dinner in London, which is usually held in the autumn. For this we have been taken to task in last week's issue by " Eye-witness," who suggests that a discussion should have been arranged in the afternoon after the delivery of the address. Perhaps, but it was not arranged. Hastily written editorials are perhaps not always plain enough. *Brevis esse laboro, obscurus fio.* To avoid any further misapprehension may we repeat, in slightly different words, that we regard the meeting at Cambridge as unusually important by reason of the many matters of public interest dealt with by the President in his Address. We believe that a full discussion of these would interest not only our readers but also a far wider public whose attention should be directed to these problems through the agency of the newspapers. The Society of Chemical Industry includes leading representatives of the academic, industrial and commercial classes, and is for this reason particularly qualified to take a wide outlook on such matters and, notwithstanding the criticism of " Eye-witness," we hope that the items we alluded to may be discussed seriously and carefully and that the discussion, at any rate of such proposals as affect chemistry in its relation to the public or the State, will be such that the public will have an opportunity of realising the importance of them.

* * *

Of the many attractive fields of speculation which abound in the vast domain of applied chemistry, none presents greater interest or wider scope for the imagination than that relating to the origin of natural products. When we come to review the state of our knowledge of such products we have to admit that, in the majority of cases, we know surprisingly little having regard to the amount of theorising which has been indulged in, and of experimenting which has in some instances led up to the formulation of the respective theories. A striking case in point is the problem of the origin of petroleum. The many theories that have been put forward to explain the genesis of this, one of the world's most valuable raw materials, may be grouped broadly as " organic theories " and " inorganic theories." The protagonists of the former theories hold that petroleum has its origin in materials of organic nature, particularly plant materials or humic acids and related compounds. Recently, too, K. Kobayashi has put forward the idea that petroleum originates from fish oils and has adduced experimental evidence to support this view. Again, J. E. Hackford is of the opinion that Mexican petroleum is derived from seaweed. The adherents of the " organic theories " will, however, have to take serious account of certain facts which at present seem to lend considerable support to the views of the " inorganic theorists " ; particularly is this the case regarding the metallic content of petroleum. In a recent note in the " Transactions " Mr. W. Ramsay publishes the interesting fact that all the fuel oils which he examined contained nickel in small, but definite, amounts, ranging from 1 to 83 parts per million, whilst petroleum pitch and asphalt held 120 to 240 parts per million ; most of these oils also contained small amounts of copper. Vanadium is another metal which has been found in oils from such widely distant sources as Egypt, Persia, and America. Ramsay points out that the presence of these metals can hardly be accidental, and he puts forward the ingenious suggestion that the presence of nickel, with its well-known catalytic powers, gives material strength to the theory of Sabatier and Senderens, that petroleum results from a process similar to that which occurred when they produced a liquid strongly resembling natural petroleum by hydrogenating acetylene at high temperatures and pressures. It will be interesting to watch the progress of the arguments for and against the various theories as they develop in the light of the facts of the hypotheses that are constantly being put forward.

* * *

The Report of the British Dyestuffs Corporation, Limited, must be agreeable reading for the shareholders of that company and satisfactory to Sir William Alexander and his colleagues on the board. It is no little achievement to show a profit of over £100,000 after making due provision for depreciation. The chairman claims, and we believe rightly, that the dye-making industry has been definitely established in this country, that the quality of our production is equal to that of the best German types, and that British makers are now able to satisfy the bulk of the requirements of the colour-using industries here. The consumer now has a security of supply which was lost to him in 1914, and enables him to face with equanimity the present uncertainty of foreign supplies. The industrial supremacy and national security of this country have in the past been mainly due to our strong position in the iron, steel and heavy chemical industries. We shall all wish Sir William Alexander, his colleagues and shareholders, success in their efforts to include the dye-making industry in this category. Surely the time is not far distant when the chemical industry of this country will no longer be divided into a strong heavy one and a weak fine one. The two are now so intimately connected that the country cannot afford that either of these shall be weak. As time goes on they will be more and more closely connected, and the sooner they are regarded as one industry and so organised that there is a great deal of mutual support and common interest, the better for all. The dye-making industry may, and we trust will, be an important means of building up again the prosperity of the country, but its intimate connexion with the fine chemical industry, the heavy chemical industry and the industry of chemical engineering is obvious. A few years ago the prospects of the dye-making industry in this country seemed very gloomy; they are difficult yet, but the courage with which the difficulties are being faced gives us every ground for hope. Every reader of this Journal will join us in congratulating the Dyestuffs Corporation on its past achievement and hoping for a great measure of further favours to come.

THE THEORY OF SPECTRA AND ATOMIC CONSTITUTION

By PROF. W. L. BRAGG, F.R.S.

This English edition of three essays by Bohr* will be universally welcomed, as it constitutes a fascinating introduction to the theory which has thrown so much light on atomic constitution. The essays which Bohr has selected to represent his work were published in 1913, 1920 and 1921. They therefore give an historical summary of the way in which the theory has been developed step by step, and it is a remarkable tribute to the intuition which has guided the author from the first, that the earliest essay still describes, with hardly any modification, the main principles which have inspired the remarkable developments during the last few years.

The first essay describes Bohr's classical theory of the hydrogen spectrum, introducing the principle which marked so radical a departure from the established way of regarding the emission of radiation by the atom, and which gave an explanation for the first time of the most fundamental feature of all series spectra, the Ritz law of combination. According to this law the very complex assemblage of frequencies in the spectrum of an element can be summarised more simply by assigning to the element several series of terms, these terms having the form first proposed by Rydberg, and expressing the frequency of any line in the spectrum as the difference between a pair of these terms each chosen from one of the series. Bohr regarded the emission of radiation as due to an alteration in the structure of the atom, resulting in a diminution of its total energy. The energy is emitted as monochromatic radiation whose frequency, given by the quantum relationship $h\nu = E_1 - E_2$, can be equated to the difference in energy of the final and initial stages, divided by Planck's constant h. If it is supposed that each series term corresponds to a possible configuration of the atom, and that the lines of the spectrum are due to transitions from one of these configurations to another, the combination principle follows as an immediate consequence.

Radiation is emitted when an electron is being recaptured by an atom from which an electron has been removed. The lines in the spectrum represent successive stages by which this takes place. If their frequencies are multiplied by Planck's constant h, we obtain a measure of the potential energy lost as an electron passes from one orbit of temporary stability to the next. The simplest spectrum is that emitted by the hydrogen atom, all the lines being represented by the formula

$$\frac{1}{\lambda} = R\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)$$

---

* *The Theory of Spectra and Atomic Constitution.* Three Essays. By Niels Bohr. *Pp. x + 126.* Cambridge: The University Press, 1922. *Price 7s. 6d.*

In this formula λ is the wave length of the line, R the Rydberg constant, n_1 and n_2 integers. The case of the hydrogen atom also lends itself readily to calculation, since the atom consists of a single electron describing an orbit about the nucleus. Bohr supposes that in the process of radiation the electron is more and more tightly bound by the nucleus, the major axis of the ellipse which it describes rapidly diminishing as it passes from one stage to the next. In order to explain the series formula for hydrogen by the quantum law, it must be supposed that the energy lost in arriving at the nth orbit is equal to $\frac{R\ hc}{n^2}$ c being the velocity of light, and n an integer which is the quantum number of the orbit. The process is complete and the stable hydrogen atom formed when n becomes equal to unity.

This is an entirely different view of the process of emission from that given by classical electromagnetic theory. According to classical theory, an electron rotating about the nucleus with a definite frequency, will give out electromagnetic radiation of that frequency, and of its higher harmonics. As the electron passes from one orbit to another in the process of being bound to the atom, its frequency continually increases, and we would expect the radiation to consist of a band of all frequencies between two extremes. This reasoning obviously fails somewhere, since in actual fact the spectrum of an element consists of sharp lines. Bohr's theory does not "explain" this failure; recognising its existence, it provides a satisfactory formula by which to calculate the frequency of the monochromatic radiation which we observe. In certain cases, however, classical theory is found to represent the observed facts. For instance, when electrons surge up and down a wireless antenna, the electromagnetic radiation which is emitted has the same frequency as the current in the antenna. In the Bohr atomic model, although the classical theory cannot indicate the frequency of the radiation when the electron passes from one orbit to another of very different frequency, there are cases where it may be expected to give a close approximation to the truth. This is so when the electron passes from one orbit of a high quantum number to a neighbouring one, for during the whole of this process the rate at which it circulates around the atom remains practically constant. It is here that Bohr's theory receives one of its most brilliant confirmations; the frequencies calculated by his application of the quantum theory become identical, in this limiting case, with those radiated by the electron according to classical theory. This may alternatively be expressed in another way. Assuming that the two theories must tally or "correspond" in these limiting cases, we can calculate a value for the Rydberg constant R from the charge and mass of the electron, which agrees exactly with that which is actually observed in the hydrogen and other spectra.

The "correspondence principle," thus outlined in the first essay, has been a guiding principle in suggesting formal relationships for more complex spectra. The series terms in these spectra, as in the case of the hydrogen spectra, again indicate different energies of configuration of the atomic system. The application of the correspondence principle to the determination of the formulæ for these series terms is developed in the second essay.

The theory is applied, for instance, to the radiation given out by the atom when placed in an electric or magnetic field (Stark and Zeeman effects) in order to explain the splitting-up of the lines into components in such fields. Electromagnetic theory indicates that the orbit of the electron around the hydrogen atom will go through a series of transformations in such a field, returning at definite intervals to its original conformation. Each frequency of radiation which is emitted in the unperturbed condition becomes a group of frequencies slightly differing from each other on account of these slow transformations. According to the Bohr theory, the splitting up of the lines corresponds to the existence of several configurations of the atom differing slightly in energy. Bohr finds formal expressions for the energies of the perturbed stationary states, which are such that in the limit quantum theory and classical theory give the same answer. He shows that the same formal expressions can be applied throughout the spectrum, and give results which are in the closest agreement with the observed effect for all the lines.

In considering these perturbed orbits the necessity for a second quantum number arises. In the unperturbed hydrogen atom, for instance (neglecting the relativity correction), it is only necessary to assume that the possible orbits are restricted to those with a definite major axis and energy characterised by the major quantum number "n." When the atom is in an electric field, the slightly different energies of the perturbed orbits must be sharply defined by a second quantum condition, involving an integer "k," in order that in the limit there may be correspondence between these energy differences and the harmonics of the cyclic changes through which the orbit goes.

The realisation of the significance of these two numbers "n" and "k" is essential to the understanding of Bohr's theory of atomic structure. This theory depends on the assignation of the correct quantum numbers to each electron in the atom, thus defining the energy with which that electron is bound to the atom, and ultimately the form of the orbit which it takes up. The electron orbits around the nucleus of an atom of high atomic weight are not simple ellipses, since the electron comes into the sphere of different fields of force in approaching and receding from the nucleus, owing to the variation in the screening effect of the other electrons. The orbit is perturbed and goes through a cycle of changes. It must, therefore, be characterised by two quantum numbers " n " and " k." In the case of the hydrogen atom in an electric field, the perturbations are so small that the energy is almost entirely determined by the " n " quantum number, and the integer " k " only produces slight alterations in the total energy which account for the splitting up of the lines. In an atom such as sodium, the perturbations produced by the complex atomic structure are very large, and the energy is greatly influenced by " k " as well as by " n. " Each series of terms in the spectrum of an alkaline element corresponds to orbits of the returning valency electron, for which " k " is a constant and " n " varies, so that there is a set of terms for every value of " k." A study of the spectrum leads to the determination of the quantum numbers " n " and " k " for every term. We can say, for instance, that the yellow line of sodium is given out when the electron goes from an orbit where $n = 3$, $k = 2$ to an orbit where $n = 3$, $k = 1$, and that the last orbit is the final stage of the process, in that no transference to a more tightly bound orbit with the emission of radiation takes place.

It is in this way that Bohr develops his theory of atomic structure in the third essay. In examining spectra, we are in fact witnessing the final stages in the building of an atom from its constituent parts. The whole process can be followed in the case of hydrogen with its single electron, but in the more complex atoms we can only watch the last electron, or the last but one, being incorporated into the structure, since under the conditions of excitation of the spectrum no more than one or two electrons are torn away from the atom. There are two ways, however, of arriving at a complete knowledge of the quantum numbers for all the orbits. The optical spectra tell these numbers in the case of the last few electrons to be added ; the X-ray spectra give information about the firmness of binding of the other electrons, since X-rays are emitted when an electron in one of the interior tightly bound orbits is removed from the atom.

It is this third essay which will make the greatest appeal to the chemist, since Bohr shows that the form of the periodic table can be predicted by a study of spectra alone. He considers the formation of the atoms in turn, commencing with hydrogen, and supposing them to be formed by the binding of electrons accompanied by the emission of radiation. In all cases where series spectra are available, they tell the orbits into which the last electrons finally settle down. In helium, for instance, the two electrons move in 1_1[*] orbits. In lithium the spectrum shows that the third electron does not join the former two, but ends its approach to the atom in a far more loosely bound 2_1 orbit, so becoming the valency electron. The electrons added during the second period culminate in neon with four 2_2 orbits and four 2_1 orbits. The valency electron of sodium does not join this two quantum group, but ends in a three quantum (3_1) orbit. The spark spectrum of calcium indicates that a previously formed group of three quantum orbits, completed in argon, will be still further added to in the succeeding elements. Hence, while the valency electrons describe four quantum orbits in the elements from scandium to copper, their number is not increased in passing from atom to atom ; the additional electrons go into an existing three quantum group to build up its numbers from eight to eighteen. From zinc onwards the inner group is complete, and the valencies of the elements pursue their usual course. During the transition stages the metallic ions possess an inner quantum group, which is only partially completed, and Bohr shows that this explains the colour, paramagnetism, and double valency of these ions.

A radical departure from accustomed ways of regarding radiation and atomic dynamics is inevitable, for it appears that the laws which have been deduced for large-scale phenomena must be modified when considering the atom. A new mechanics has to be framed, and this constitutes the main difficulty in the investigation of atomic constitution. Whatever may be the significance of the formal relationships which Bohr proposes, there can be no doubt of their accuracy, and of their power in correlating a vast number of phenomena.

THE REFEREEING OF SCIENTIFIC PAPERS

By T. S. PATTERSON

Most authors of scientific papers will probably agree that our methods of refereeing leave something to be desired, and I should like to raise the question here in order, if possible, to elicit from others interested in the subject, suggestions for improving the procedure. I do not take up the question with any very strong personal feeling, not having had much reason to complain[†] in regard to my own papers, but I do feel that the method adopted, at any rate by the Chemical Society, is one which, for extremely little that it produces of value,[‡] gives rise to an entirely disproportionate amount of irritation. As I am most familiar with the procedure adopted by the Chemical Society, it must be understood that, in what follows, I refer to their practice.

---

[*] $n = 1$, $k = 1$.

[†] Of refereeing : literary form is another question.

[‡] I can in fact only recall one single instance in which I was really glad to adopt a suggestion made by a referee ; only one instance in which the referee succeeded in discovering what would have been an actual mistake in the paper.

The majority of papers sent to the Chemical Society, although considered by the referee to be worthy of publication, are also thought by him to require some alteration, and it is here that trouble is apt to ensue. The autocratic command to alter or omit certain passages, which reaches him through the editor from an unknown referee, seldom makes a sympathetic appeal to an author. He feels that there is something to be said on his side, and it is very difficult for him to carry on an argument, through an intermediary, with an anonimity.

It would be vastly better if, in some way, the author were put into communication with the referee in order that any debatable points might be adequately discussed. It is objected to this, and certainly with some reason, that a referee might be thus involved in a certain amount of, perhaps uncongenial, correspondence. It may be that some referees would either be so afraid of giving offence or would have so little confidence in their own judgment that they would not care even for this modified procedure, although I believe that it would tend considerably to lessen friction between the Publication Committee and the author. At least it might be tried; it would help to ensure that the refereeing of a paper, upon which, after all, much may depend, should not be done in any perfunctory manner. I should myself always be glad to hear from a referee what impression my paper had made upon him and how, if it seemed necessary, it might be made clearer. As things are now, it seems hardly worth while to put a paper into final form before sending it to the Society. If some trouble has been taken in writing the paper, so that its parts are closely knit together, it is often exceedingly difficult to cut out some portion, even a small portion, here or there, because this may easily alter the whole structure of the remainder.

But if a referee prefers to remain anonymous and the author, unable to accept his suggestions, cannot get into touch with him, then I would suggest that the author should be invited to choose a referee agreeable to the Committee, to whom the paper might be submitted for an opinion on any point in question, and with whom the author could communicate direct. Most authors would be quite willing to accept the decision of the referee whom they had themselves chosen or had a say in choosing.

A third method by means of which scientific papers might be dealt with is the simplest of all. It is that which, as far as I can judge, used to be practised by the German Chemical Society. A paper submitted to the Society was read by the editor, who, if he found it suitable, might perhaps make some slight suggestions for its modification or improvement—although in my own experience I remember none such—and if he then thought the paper suitable for publication, immediately sent it to the printers. A paper which either seemed unsuitable for publication, or else to require considerable modification, he could send to a referee.

Another method might be to allot to a paper which had been generally approved a certain number of pages, and leave the author to do the best he could with that. He might then tell his own tale exactly in his own way, which would make for greater originality in the presentation of his subject. He would probably write with a keener sense of responsibility than when he feels that there is a referee in the background, and the result in the end would be both more satisfactory and easier to achieve. In fact, if an author had attained to some standing as a contributor to a journal, he might well be trusted to write his papers without the assistance of a referee at all.

The most obvious difficulty for the referee is, of course, to have to advise the rejection, or even a very fundamental reconstruction of a paper. But this might be met by withholding always the name of the referee until his report had been submitted, and if his report were very definitely adverse, withholding his name altogether in order that a second, absolutely independent and unprejudiced, opinion might be taken. If both referees advised rejection the Committee might, with some confidence, act on their recommendation. Even then, however, I consider that the author should have a say in the selection of the second referee. As I think the matter is of greater consequence than seems sometimes to be realised by those who decide the fate of other people's papers, I trust it may be ventilated in the columns of *Chemistry and Industry.*

University of Glasgow

CHEMICAL SOCIETY'S LIBRARY

Owing to the work of redecorating the rooms of the Society, the Library will be closed during the entire month of August.

The Library will therefore close on Tuesday, July 31, at 9 p.m., and reopen on Saturday, September 1, at 10 a.m.

The Library, in accordance with the usual practice, will be closed at 5 p.m. from September 1 to 17, on and after which date it will remain open until 9 p.m. every day except Saturday, when it will close at 5 p.m.

A

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

DYESTUFFS AND HEAVY CHEMICALS.

At the recent Brunner Mond & Co. dinner, Sir William Alexander made a very good speech, carefully prepared and excellently delivered. It dealt in an interesting manner with the history of the company whose jubilee we were celebrating, and every now and then there was a comparison of the dyestuff with the heavy chemical industry. Occasionally there was a reference to the struggle through which the dyestuff industry has just emerged and the advantages of cooperation between the two branches of the industry. All of which set me thinking. There is the heavy chemical industry well established, developing under its guidance is the production of ammonia from atmospheric nitrogen, and now the prospect opens out before us of the linking of the dyestuff industry with it. One hardly knows what to think of such a prospect, but one thing is certain, it would mean an additional menace to the German Chemical Industry.

THE CHEMICAL SECTION

of the British Empire Exhibition is, I am told, now quite full, and those who have delayed until now are finding it difficult to obtain any space for their exhibits. I was shown a letter from Dr. Ruttan, the ex-President of the Society, who is hoping that Canada will cooperate with the Mother Country in the pure chemistry part of the section. Whether this can be arranged I do not know, but I imagine that Dr. Levinstein, who is the Chairman of the Committee dealing with that portion of the exhibit, will welcome any example of distinctive work from the Colonies. The only difficulty I foresee is that each of the Colonies has its own exhibit, and may be unwilling to allow any scientific novelty to be placed anywhere, except in the very ample spaces taken by the Colonies.

THE BRITISH DYESTUFFS CORPORATION MEETING

last Tuesday was not the vigorous affair we were treated to last year. Circumstances have changed for the better, and although the Corporation is by no means out of the wood, the shareholders had evidence that the position has been consolidated. Hence there was a change in the tone of the meeting, and Sir William Alexander's speech to his shareholders was listened to with a great deal of interest. The position in the dyestuff industry at the moment is most interesting and anything may happen. Two absolutely contrary views are being put forward as to the action of the French in removing German dyestuffs from the Ruhr and its effect on the British industry. The more general opinion in the industry seems to be that the flinging of the dyes which have been taken on to the open market to fetch anything they will, must have a paralysing effect on the British industry from which it might never recover. On the other hand, I did hear that a singularly competent observer holds the view, that after a temporary depression in prices there will follow a shortage of dyestuffs all over the world which will raise prices and set the British industry on its feet once more. The industry has suffered from crisis after crisis ever since the war, and I imagine that having been "threatened" so often its leaders are becoming inured to such scares.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

this week completes its seventh year, and the Annual Meeting and dinner took place yesterday (Thursday). Circumstances have conspired to make this Association rather more truly representative of the industry than similar associations usually are. One is familiar with the association or society devoted to the furtherance of some scientific object: it usually has a small subscription and a large membership. Then you may have an association where the relative sizes of the subscription and membership are reversed; its object is, quite frankly, to make money for its members, and unless it does so it fails to retain its members. The Association of British Chemical Manufacturers falls into neither of these groups. It has a small membership, but it represents a very large amount of capital invested in the industry. The annual subscription is a large one, although graduated according to the capital of the company member. It gives no direct return for the large annual subscription it demands, yet its membership shows no diminution.

THE EXPLANATION OF THE PARADOX

is to be found in the broad basis on which the Association was built seven years ago and the wise restraint exercised by the Council in its development. Think of what our British Chemical Industry really is; it is in fact a collection of inter-related industries with scientific chemistry for their basis. If you are to group these industries under one head for purposes of representation and collective action, you must allow sufficient freedom of action for the various groups, and this the Association does by its group system. When all the groups are interested and unanimous, the Association acts in its corporate capacity in the dissemination of information and in parliamentary and transport matters for example. With this kind of organisation the individual groups in the course of their development by "trial and error" gradually work out for themselves the lines on which they can obtain the greatest possible good from combining with other groups.

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of Council was held on June 21, 1923 at the Arts School, Bene't Street, Cambridge, the President, Dr. E. F. Armstrong, F.R.S., in the Chair.

Prof. Harold Hibbert, of Yale University, U.S.A., representing the American Section of the Society, was present by invitation.

It was reported that the Committee of the Chemical Engineering Group had agreed, at the request of the Council, to organise both the Chemical and Physical sections of the World Power Conference, to be held in June, 1924, at the British Empire Exhibition.

It was decided to hold the Annual London Dinner of the Society in November.

The Society's annual contribution to the Federal Council for Pure and Applied Chemistry was renewed for 1922.

The reports of the Hon. Treasurer and of various Committees of the Council were discussed, and 23 new members (Home, 17 ; Australia, 2 ; India, 1 ; U.S.A., 1 ; Japan, 2) were elected.

On the proposal of Sir Wm. Pope, the following were unanimously elected honorary members of the Society :—Prof. C. F. Chandler (U.S.A.), Prince Ginori Conti (Italy), Monsieur Paul Kestner (France), Prof. Joji Sakurai (Japan), Sir Dorabji J. Tata (India).

The revised Rules of the Chemical Engineering Group were approved.

It was agreed, at the request of the Executive Committee of the National Gas Exhibition, 1923, to allow the name of the Society to appear in the list of patrons, and that the President should be a Vice-president of the Exhibition.

The President was nominated the Society's representative at the meeting of the British Association for the Advancement of Science, to be held in Liverpool on September 12 to 19.

As no meeting of Council will be held until October, the following members were appointed an Executive Committee to deal with matters of urgency arising in the meantime :—The President (Dr. E. F. Armstrong), the Hon. Treasurer (Mr. E. V. Evans), Mr. J. L. Baker, Mr. C. S. Garland, Sir Wm. Pope, Mr. Edwin Thompson, and Mr. W. J. U. Woolcock.

It was reported that Mr. C. F. Cross had represented the Society at the Centenary Meeting of the Société d'Encouragement pour l'Industrie Nationale de Paris, and that Prof. R. H. McKee, Chairman of the American Section, had similarly attended the inauguration of Prof. Stratton at the Massachusetts Institute of Technology.

The date of the next meeting was fixed for Friday, October 12, 1923, at 2.30 p.m.

CORRESPONDENCE

DR. EHRHARDT'S PAPER ON "PATENT CLAIMS FOR PRODUCTS"

Sir,—My attention has been called only within the last few days to Dr. Ehrhardt's admirable paper, entitled, "Patent Claims for Products," appearing in your issue of March 29 last. In it he discusses the case—In the Matter of Applications for Patent by W. K.-J., and W. Ltd., reported in Vol. 39 Reports of Patent Design and Trade Mark Cases at p. 263 —and its bearing on applications for Patents for new chemical substances, *e.g.*, new azo-dyes. He suggests that the Law Officer's decision in that case in so far as it interprets the word "special" in Section II of the Patents and Designs Act, 1919, renders an application for a patent for a new azo-dye, produced "in the usual way with a well known component," liable to rejection, because its method of production would not be "special."

In the case referred to the Comptroller-General raised no objection before the Law Officer to Claim 1 for the process of making the bread, giving as the reason that the claim involved chemical action during the baking stage, nor to Claim 6, which was in these words, "Bread prepared or produced by the special methods or processes of manufacture above described and claimed." The Law Officer's decision contains the following passage :—

"Lastly I have to deal with the meaning of the word, 'special.' In my judgment given upon an application by 'M.,' I have decided that the word is used not in respect of a new mixture of ingredients ; but in order to connote a method or process which has such attributes that it is the proper subject of a claim for letters patent, one that has some intrinsic characteristics which are the invention of the inventor and for which a patent may be properly and legitimately claimed and granted."

In the Law Officer's decision in the case—In the Matter of M.'s Application for a Patent (reported *loc. cit.* at p. 261)—the following passages occur :—

"In my judgment the word 'special' is introduced, in addition to the word 'described,' in order to connote that the particular method or process set out in the specification must contain the essentials of a valid patent-novelty, a manner of new manufacture—a process which produces by its own chemical reaction a new substance. It must be a method, or process, which has such attributes that it is the proper subject of a claim for letters patent, one that has some intrinsic characteristics, which are the invention of the inventor and for which a patent may be properly and legitimately claimed and granted."

"An applicant may not solely mix certain ingredients by known processes and say that he has produced a new medicine that can be the subject of a patent. That is merely to introduce a prescription to the world. But he may, by a new manner of manufacture, produce a new medicine or substance hitherto unknown, which would be the proper subject of letters patent. This might be produced, for example, by chemical reaction with properties resulting therefrom, be it by some process newly discovered, or by chemical reaction of the ingredients."

I do not think it necessary to discuss the facts, or the Law Officer's application of his interpretation of the Section to the facts of these two decisions, but it is sufficiently clear from these extracts that Dr. Ehrhardt is in error in thinking that the application for a patent for a new azo dye would be beset with difficulties by reason of the meaning given to "special" in these decisions. Such an application would be concerned not with a mere prescription, but with a process involving and dependent for its results upon chemical action and, accordingly, the process would be a "special" one within the meaning of the section as interpreted by these decisions.—I am, Sir, &c.,

Arthur Colefax

July 3, 1923

THE CASSITERIDES

Sir,—The identification of the Cassiterides is a difficult problem. There have been three main theories: the locality was off the North-West coast of Spain; it was Britain, *i.e.*, Cornwall, including the Scilly Isles; it was imaginary. The latter theory, advocated in the "Encyclopedia Britannica," need hardly be considered. The Spanish theory, although it appears to be supported by the descriptions of Diodorus Siculus and Strabo, both of whom probably drew on the same source, suffers from the defect that there are no islands off the coast of Spain which produced tin. The British theory, which is advocated by most modern writers (I may refer to Mr. T. R. Holmes' "Ancient Britain," Oxford, 1907, pp. 483 ff., to Prof. Lippmann's "Alchemie," 1919, p. 583—he gives a most exhaustive literature collection, but omits Holmes; Reinach, "L'Anthropologie," 1892, vol. 3) has a good deal in its support. These authors quote all the classical authorities in detail. The position of the Cassiterides seems to have been correctly given by Pytheas, about 360 B.C., from his own travels; the source of the Spanish theory was later, and is traced by Berger ("Geschichte der wissenschaftlichen Erdkunde der Griechen," Leipzig, 1903, p. 512) to Polybios (*c.* 200 B.C.). The charge brought against me by my editorial critic that I was guilty of propagating an old and exploded error, presumably owing to ignorance, I must vigorously repudiate.—I am, Sir, etc.

J. R. Partington

45, Kensington Gardens Square
July 7, 1923

Sir,—After reading your editorial on the subject of the Cassiterides I looked at Ptolemy's map of the world and compared it with a modern map. Although Ptolemy flourished about a century later than the ancient writers whom you mention; you ought, nevertheless, to allow him to appear as an expert witness. Bearing in mind the state of geographical knowledge in his time, I think that his evidence is conclusive that the ancient Cassiterides are the same as the Scilly Isles.

If Diodorus and Pliny were familiar with some such map as Ptolemy's, they would naturally describe the Cassiterides as "above Lusitania . . . lying off Iberia in the Ocean," and as "opposite to Celtiberia."—I am, Sir, etc.,

R. H. Atkinson

26, Maids Causeway, Cambridge
July 8, 1923

I am afraid I have put my foot into a hornet's nest, but plead not guilty to the fault which Prof. Partington attributes to me. I do not think any words of mine imply that he was ignorant of the subject. It is now obvious, and I already knew it when I wrote my article, that he was well acquainted with the literature on the subject, and I suspected him of having an acute and logical mind. My criticism was really that people are apt to go to modern books about such points when the original information is available. Now Prof. Partington refers to Holmes, Lippmann, Reinach and Berger, but I should prefer his own opinion on what the early writers said.

Herodotus says, "nor am I better acquainted with the Islands called the Cassiterides from which we are said to get our tin." (iii., 115). I have already quoted Diodorus and Pliny. Posidonius says that tin was dug up among the barbarians beyond Lusitania, and in the islands called Cassiterides and also in Britain. Pomponius Mela, after locating the Celtici in the neighbourhood of the Douro, says:—"Among the Celtici are several islands all called by the single name of Cassiterides because they abound in tin." (Mela iii., 3, 6.) Prof. Partington says "the position of the Cassiterides seems to have been correctly given by Pytheas, about 360 B.C., from his own travels." The writings of Pytheas long since disappeared except for some references to him or quotations in Strabo, Ptolemy, Geminus, Stephanus Byzantius, Plutarch, Hipparchus, the Scholiast on Appollonius Rhodius, and three or four other authors. Will Prof. Partington kindly tell us what ancient author quotes such a statement of Pytheas? I have not come across it in the references I have so far had time to turn up. I also invite him to quote any author prior to, say, 100 or 150 A.D. who states anywhere that the name Cassiterides is applied to Britain. I have furnished him with three or four references which do not. There was an old tradition that there was a tin island in the Indies, and having read most of the early passages relating to the Cassiterides I am of opinion that the old Greeks did not know very clearly where their tin came from, and that the identification of the Cassiterides (as they used the word) with Britain is without foundation.

In reply to Mr. R. H. Atkinson, the writings of Ptolemy might be of interest on such a point ; a modern reproduction of a mediæval map, supposed to have been copied from some earlier map prepared by Ptolemy is not very much good, but what particular map has he in mind ? There is a map in a well-known Latin Ptolemy of 1478 ; if Diodorus and Pliny based their views on such a may as this they would be perfectly clear that the Cassiterides were not the same as the Scilly Isles.

THE EDITORIAL CRITIC

PRESIDENTIAL ADDRESS

SIR,—On reading through the President's address to the recent Annual Meeting of the Society of Chemical Industry, I notice what is either an omission or a mistake to which I think it is worth while to draw attention.

Of the Research Association to which the President referred, the first to be formed, the Photographic, completed its first five years in May of this year. Unfortunately the financial position of the Photographic industry, comparatively a small industry, is at present at a very low ebb, and it is not yet quite certain whether it will be found possible to continue the Association. I do not know whether this should be attributed in any way to a too literal acceptance by the responsible heads of the industry of the dictum laid down by the President in another part of the address that the object of industry is definitely financial, a dictum which I am pleased to see produced a protest from Dr. Heathcote in your issue of June 29th. I think it more probable that it may be ascribed to the fact that the work of the Association has been concerned, and rightly so, with the fundamental principles underlying photographic processes, and that it has therefore made a less direct appeal to the industrial director than work which is concerned with the discovery of new processes, or the improvement of existing ones. In times of financial stress, such as the industry is now experiencing, the continuance of subscriptions to such work is one of the first things to be imperilled.

Considering the difficulties with which the Association has had to contend in its first five years, a change of directorship in the third year being one of the chief of these, it is somewhat surprising how much valuable research work has been accomplished, and how well established its reputation has become over the whole world for careful and accurate work. That the energies of the director, Dr. Slater Price, and his co-workers should be suddenly switched into other channels, and the various researches in progress should be suddenly stopped, would be a very serious loss, not only to photographic research in particular, but to scientific research in general—not only to the photographic industry in particular, but to all those industries which in one way or another make use of photographic methods or material in their own work.—I am, Sir, &c., B. V. STORR.

FORTHCOMING EVENTS

July 13 and 14.	THE FARADAY SOCIETY, Department of Physical Chemistry, Cambridge. Friday afternoon and Saturday morning. General Discussion on "The Electronic Theory of Valency."
Sept. 10–13.	THE INSTITUTE OF METALS. Annual Autumn Meeting, to be held in Manchester. "The Use of Non-Ferrous Metals in Engineering," by Lieut.-Colonel Henry Fowler. Tickets are obtainable from Mr. G. Shaw Scott, M.Sc., 36, Victoria Street, S.W. 1.
Sept. 12–19.	The British Association for the Advancement of Science. Ninety-first Annual Meeting, Liverpool. Among the papers to be read are the following:—(1) "The Electrical Structure of Matter" (Presidential Address), by Prof. Sir E. Rutherford, F.R.S. (2) "The Origin of Spectra," by Prof. J. C. McLennan, F.R.S. (3) "The Physical Chemistry of Interfaces," by Prof. F. G. Donnan, C.B.E., F.R.S. (4) "The Position and Opportunity of the British Empire," by Dr. V. Cornish. (5) "Unemployment and Population," by Sir W. H. Beveridge, K.C.B. (6) "Transport and its Indebtedness to Science," by Sir H. Fowler, K.B.E. (7) "The Education of Demos," by Prof. T. P. Nunn. (8) "Science and the Agricultural Crisis" by Dr. C. Crowther. Membership Fees, £1 and upwards. Students' Tickets, for duly qualified persons, 10s. Full particulars can be obtained from the Secretary, British Association, Burlington House, London, W. 1, or from Local Hon. Secs., British Association, Manesty Buildings, College Lane, Liverpool.

PERSONALIA

Prof. A. C. Neish has been elected President of the Canadian Institute of Chemistry.

Monsieur Jean Perrin, professor of physical chemistry at the Sorbonne, has been elected a member of the Académie des Sciences. Prof. Perrin is the author of classic researches on the constitution of matter and is at present engaged in investigations on the changes of matter induced by light which promise to furnish an explanation of the phenomena of radioactivity.

* * *

E. F. Dyer, a well-known expert in the United States sugar industry, has died at the age of 65 years.

The death is announced, at the age ofseventy, of Prof. J. Nevinny, professor of pharmacology, in the University of Innsbruck.

The death is announced of Monsieur P. Mossot, director of the Société Métallurgique de Knutange and president of the Association des Maîtres de Forges de Lorraine.

The death is announced from Germany of Heinrich Baum, a well-known worker in the field of Azo colours, and the originator of Coccinin and many other colours. Also of Prof. B. Martiny, the founder of the modern German milk industry.

From Germany the deaths are announced of Dr. H. Liebmann, chemist to Bayer und Co., Leverkusen; W. Eckhardt, managing director of the Brüder Passer Factory; Dr. O. Spanjer, director of the Upper Silesian Portland Cement and Lime Works; of W. Hollweck, who was responsible for many improvements in firing technique in the gas industry; and of R. Schmidt, a director of the A. G. für Anilin Fabrikation.

NEWS AND NOTES

AUSTRALIA

The Sugar Industry.

According to the latest returns the output of raw sugar in Queensland in 1922 was 288,928 tons from 2,176,949 t. of cane harvested on 149,863 acres; in 1921 the figures were 282,198 t., 2,287,416 t., and 122,956 acres, respectively. The production of sugar in New South Wales in 1922 is given as 17,267 t., an increase of 483 t. over the previous crop. —(*Ind. Tr. J., June* 7, 1923.)

CANADA

Profits in the Italian Chemical Industry

It is announced in the Roman Press that during the first half of 1922, 47 out of 57 chemical companies representing a total capital of 355,000,000 lire made a profit of 28,000,000 lire, the remaining 8 companies making a loss of 6·8 million lire.—(*Chem. Ind., June* 2, 1923.)

FRANCE

Societe de Chimie Industrielle

The Third Congress of Industrial Chemistry will take place at the National Academy of Arts and Sciences, Paris, from October 21 to 26, 1923.

The Société de Chimie Industrielle has extended an invitation to members of the Society of Chemical Industry to attend this Congress as delegates. and the secretary of the Société entertains the hope that many of these delegates will be willing to present papers at the different sections of the Congress.

It is hoped in this way to strengthen the bond which already exists between the two associations.

The Turpentine and Rosin Industry

The production of turpentine and rosin in France during the last 10 years has been as follows :—

Year	Turpentine Metric tons	Rosin Metric tons
1913	25,000	85,000
1914	19,000	64.000
1915	15.000	51,000
1916	17.000	60,000
1917	17,000	60.000
1918	20.000	60.000
1919	25,000	85.000
1920	35.000	120,000
1921	31,000	105,000
1922	32,000	118,000

In normal years France is responsible for roughly one-sixth of the world output; the United States furnishes roughly four-sixths. Official statistics for 1922 are not yet available, but from private sources it appears that the export during 1922 consisted in 9105 tons of turpentine and 58,136 t. of dry rosin, figures which indicate that over 28 per cent. of the output of turpentine and slightly under 50 per cent. of the production of rosin were exported. The chief markets for rosin are Germany, Belgium, England, Italy, Holland and Poland, England and Belgium taking the largest proportion of the turpentine. Practically the whole of the French output originates in the province of Bordeaux.

Notes from Paris

The Cabinet has recently decided to allocate 5 million francs from the profits made by the "Consortium des Pétroles et Essences" to exploration for petroleum in France and the Colonies. It is understood that the scientific committee of the "Direction des Pétroles et Essences" will shortly proceed to examine a scheme of exploration extending over five or six years. It has already been decided to send a commission to study the geological and economic conditions in Madagascar with a view to exploiting the island's resources of petroleum.

The French Association for the Advancement of Science is to hold its annual meeting at Bordeaux, from July 30 to August 4.

The "Societé d'Encouragement pour l'Industrie Nationale" has recently celebrated the 122nd anniversary of its foundation. Mr. C. F. Cross, F.R.S., represented the Society of Chemical Industry and the Chemical Society at the opening meeting, and made a speech extolling French contributions to science. The proceedings included the presentation of numerous papers and visits to factories, etc.

AUSTRALIA

Mineral Output of Queensland in 1922

The value of the mineral output of Queensland in 1922 was £1,791,333 which represents an increase of £334,897 over the value of the output in the previous year. The following figures give the quantities and ore values in 1922 :—

1922	Quantity	Value
Copper	—	£321,535
Gold	80,584 fine oz.	£342,300
Coal	958,519 tons	£840,472
Coke	5,265 tons	£8,762

A general improvement is reported in tin, lead, silver, and gold-mining. The State boring for petroleum at Roma has been abandoned, but a private syndicate has carried on the work. Important discoveries of copper and cobalt ores have been made in the Kloncurry district.—(*Ind. Aust., May* 3, 1923.)

GENERAL

German Reparations Duty

In a written answer Sir W. Joynson-Hicks informed Mr. W. A. Jenkins that the amount collected under the German Reparation (Recovery) Act was £3,709,000 for the year ending March 31, 1922, £7,474,000 for the year ending March 31, 1923, and £1,397,000 for the two months ended May 31, 1923. The percentage rate of the levy was reduced from 50 to 26 per cent. after May 13, 1921.—(June 28.) .

Mineral Output of Algeria in 1922

During 1921 Algerian mining passed through a crisis which left it at the end of the year with stocks on hand exceeding 700,000 tons, principally of iron ore. During 1922, however, there was a general improvement as will be seen from the following figures showing the output of various minerals during 1921-1922 :—

	1921	1922
Phosphates	372,019	525,396
Ores :		
Iron	684.964	1,294,907
Copper	2,007	1.901
Lead	11.421	14,118
Zinc	17,537	39,405
Antimony	320	1,645
Manganese	1,893	—
Kieselguhr	1,563	3,425

The value of the export of minerals in 1922 was 110,000,000 francs compared with 69,000,000 francs in 1921.

Nickel in New Caledonia

The Institut Colonial de Marseille, reports that the Société des Hauts-Fourneaux in New Caledonia is now resuming full production as its stocks of nickel matte are partly cleared and the world market has improved. Coal obtained from the mines at Moindou has proved satisfactory and a plant is being installed to ensure regular supplies, in order to reduce the importation of Australian coal and coke The smelting works of the Société le Nickel will soon be consuming 4000 m.t. of nickel ore per month, compared with 2500 m.t. a year age. No new mines have been opened however, as the present one, combined with actual stocks, suffices to supply the works. Much difficulty is being experienced owing to the shortage of labour. The Société le Nickel is contemplating the production of chrome from an abandoned mine.

Proposed International Chemical Congress in South America

We are informed that it is proposed to hold the first chemical congress in South America in 1923. As the first National Congress held by Argentine chemists in 1919 was so successful—the transactions published in connexion with it fill four stout volumes—the Argentine Chemical Union has approached all the other chemical organisations in South America, with a view to organising an International Congress of South American chemists.

PARLIAMENTARY

HOUSE OF COMMONS

Patent Medicines

In answer to Lieut.-Colonel Fremantle's enquiry as to whether it is proposed to introduce a Bill to give effect to the recommendations of the Select Committee on Patent Medicines, Mr. Chamberlain said that in the present state of business the Government could not undertake to introduce legislation on this subject during the present Session.—(July 4.)

Coal Output and Royalties (Yorkshire)

Answering Mr. Lunn, Lieut.-Colonel Lane-Fox said the total output of saleable coal in Yorkshire during the year ended March 31, 1923, was 43,266,000 tons. He could not say what was the amount paid in royalties in Yorkshire alone ; in the eastern district, comprising Yorkshire, Nottinghamshire, Derbyshire, Leicestershire, Cannock Chase and Warwickshire, with a total output of 85,154,000 t., they amounted to £1,505,000. Royalties were not assessable to local rates in these districts.

To Mr. Lunn's further enquiry, Lieut.-Colonel Lane-Fox replied that he was not aware of any intention on the part of the Government, either to nationalise the minerals, or to introduce a Bill to make the minerals public property.—(July 4.)

Pasteurisation of Milk

In a written answer to Mr. Adams, Mr. Chamberlain stated that it was expressly provided in the Milk (Special Designations) Order, 1923, that the milk sold as "pasteurised" milk should not be heated more than once. The danger arising to public health from the sale of reheated milk, however, was not such as to justify the issue of special regulations which in present circumstances might result in restricting the supply of milk.—(July 4.)

White Lead Convention

Sir M. Barlow in a written answer to Mr. A. Greenwood said that he was aware that the International Materials' Committee, representing the Master Painters' Federation of England and Scotland, and the Association of Ireland, had declared in favour of the ratification of the White Lead Convention; also that the operatives in the painting trade had also declared themselves in favour of ratification. He added that the ratifying of the Convention by the Government was being carefully considered in the light of all the circumstances, and that the decision would be announced as soon as possible.—(July 4.)

REPORT

Report on Economic Conditions in France to March, 1923. *By* J. R. Cahill, *H.M. Commercial Counsellor, Paris. Pp.* 129. *Department of Overseas Trade. H.M. Stationery Office*, 1923. *Price* 3*s.* 6*d.*

The report opens on an optimistic note, pointing out that the present economic position of the country is strong. The industrial population is fully employed, the reconstruction of the devastated areas is almost complete, and agriculture is fast approaching pre-war conditions. In general the resources of the country are being developed and improved industrial organisation has led to consolidation of the basic industries on regional and national lines. Foreign trade is bigger than before the war. The country is still suffering, however, from war losses and the present employment of the population is no doubt due to the demands of reconstructional work, but it is hoped that France will inspire confidence and maintain her present strong position.

The trade policy of the Government is one of protection. British trade with France, however, in spite of high tariffs and the depreciated franc, has shown signs of improvement. Important commercial treaties were entered into in 1922 by France with Spain, Italy, Canada, Poland, and other countries. Restrictions on imports were largely removed in 1922 but the export of iron and steel scrap was prohibited last December. Exports in 1922 were valued at 20,642 million fr., and imports at 23,900,000 million fr., against 19,773 million fr. and 22,067 million fr. respectively in 1921. Among the items exported in 1922 were (in million fr.):—Sugar, 348 million fr.; ores, 238; iron and steel, 1003; coal, 354; chemicals, 633; perfumes and soaps, 213. Imports included:—Sugar, 657 million fr.; coal, 2392; copper, 351; mineral oils, 945; nitrate of soda, 127; iron and steel, 532; chemicals, 385.

As mentioned above French industry and production is in an improved position. Factories were erected in all parts of the country during the war occupation by Germany of the industrial areas, and the new factories erected in occupied regions are improvements upon those they replace. The coal industry has been extremely active since the beginning of 1922. Output has been checked only by the difficulties of labour and the state of the pits; in 1922 the output of coal was 31·91 million tons. In the first ten months of the year 17 million tons of iron ore was produced. During 1922 the number of blast furnaces alight increased from 73 to 116, whilst pig-iron output amounted to 5,128,600 t., and steel to 4,471,300 t.

The potash output has been much increased from that obtaining under German rule, and in 1922, 540,000 tons of potash salts were exported. In future the fields are to be worked by a single company, profit-making, but of public utility character. France is now the principle European producer of bauxite. Oil development is taking place, but the production is still relatively unimportant in France. Water-power is being developed and schemes have been formulated for the working of 1·5 million horse-power of the 8 or 9 million h.p. available.

TARIFF CUSTOMS EXCISE

British India.—A schedule is given containing a list of goods with revised rates of duties. Among the various articles are included gums, resins, lac, hides, iron, steel, oils, kerosene and motor spirit, sugar, silk and chemicals.

Finland.—A new customs tariff has been proposed, which will provide for a reduction of duty on silk goods, and an increase of the duty on sugar.

Poland.—The consumption tax has been increased on crude oil products and on coarse and refined sugar. The excise duty on sugar has been raised from 150,000 to 280,000 Polish marks per 100 kilogs.

Switzerland.—Reduction has been made in the import duties on certain kinds of iron.

REVIEWS

SYNTHETIC RESINS AND THEIR PLASTICS. *By* CARLETON ELLIS. *Pp.* 514. *New York: The Chemical Catalog Co., Inc.,* 1923. *Price,* $6·0.

Synthetic resins are beginning to play an important part in industry. In England manufacturers are touching only the fringe of this promising field, whereas America has been the pioneer in establishing a profitable business in the manufacture and use of artificial resins of all kinds. The latter country is in an exceptional position, by reason of its natural resources, to hold the market in the various resinous substitutes, which have been introduced of recent years for industrial use, and it has now again taken the lead in providing a reference book on the intricate subject of synthetic resins.

At the outset it may be said that the book under review serves to establish the impression of the growing stability of these new manufactures, and of the large and promising field for future development. Mr. Ellis merits the gratitude of the chemist and manufacturer interested in synthetic resins. The literature of the subject is exceedingly meagre, and consists mainly of isolated articles in the chemical and technical journals, and of patent specifications. The author has devoted much care to the wearisome task of collecting and arranging this widely-scattered and miscellaneous information, and he has also included results from his own researches. He has had the advantage of criticism and information from American technical chemists and engineers concerned in the manufacture and use of these resins, notably Dr. L. H. Baekeland, the originator of the most widely known synthetic resin, "Bakelite."

The varieties of resins dealt with, and their applications, are too numerous to catalogue briefly here. Those produced from aldehydes and phenolic bodies naturally occupy considerable space in the book; cumarone and indene resins are fully considered; and much data are given in regard to the newer and lesser-known substances, such as furfural resins, urea resins and the resins from polybasic acids and glycerin.

The practical nature of the book may well be judged by the four concluding chapters, dealing with the use of resins in moulding compositions. Much detail is here given by one who evidently has an intimate knowledge of the technical difficulties involved. A great deal of this information has remained until now in the private possession of the expert in the manufacture of moulded articles, the moulding foremen and skilled operators, and its publication therefore marks a distinct step in advance. Plates are included in these chapters, showing the types of machinery necessary for the successful working of moulding compositions. These illustrations are naturally—but unfortunately, from the point of view of the British user — of American machinery. American methods of testing moulded articles for use in electrical insulation are described. Here again, the chemist in this country may be preferably referred to the methods recommended by the British Electrical and Allied Industries Research Association (*Beama*, 1922, p. 374).

It is, perhaps, worth while to comment on the author's remarks relative to the nomenclature of the resins loosely termed *phenol-condensation products*. Mr. Ellis says rightly that it is better to make general use of the term *phenol-formaldehyde resins*. Moreover, it may be remarked that to obtain a still more general, and at the same time, accurately descriptive term, *formaldehyde resin*, can be used.

The general arrangement of the matter is reminiscent of Worden's *Nitro-cellulose Industry*, and Mr. Ellis has evidently endeavoured to provide the same careful presentation of detail for the synthetic resin industry, as was done for the nitro-cellulose industry. The binding, paper and print are good, typographical errors almost entirely absent, and altogether, the book is a valuable and interesting addition to the technical bookshelf, and certainly a source of inspiration for the synthetic-resin chemist.

ALAN A. DRUMMOND

THE SPECTROSCOPE. *By* T. THORNE BAKER. *Second edition. Pp. vi*+208. *London: Baillière, Tindall and Cox,* 1923. *Price* 7*s*. 6*d*.

Although the existence of the coloured spectrum of white light has been known from a very early date—certainly from the time of the Deluge—the foundations of the science of spectroscopy were laid only in 1859 as a result of the work of Kirchhoff and Bunsen at Heidelberg. Writing to Roscoe in that year, Bunsen refers to the discovery by Kirchhoff of the origin of the Fraunhofer lines in the solar spectrum, and remarks "thus the way is pointed out by which the material composition of the sun and the fixed stars can be ascertained with the same degree of certainty as we can ascertain by our reagents the presence of SO_3 and Cl. By the method, too, the composition, of terrestrial matter can be ascertained. . . ." Bunsen's modest anticipations were speedily fulfilled. By means of the spectroscope the new elements, cæsium, rubidiun, thallium, indium, germanium, gallium and scandium, were discovered in the period 1860-1879. What shall we say of modern applications and developments of the science? The electron, atomic structure, molecular configurations, isotopes and the curvature of space in the region of gravitating matter are a few among modern physical conceptions with which spectroscopy is intimately concerned. How exacting are the demands of modern spectroscopy may be illustrated by the fact that one of the crucial phenomena in Einstein's Theory of Relativity requires the measurement of a difference of wave lengths in the spectra of solar and terrestrial sources equal to 0·008 Å. U. (*i.e.*, 8×10^{-10} mm.). The spectroscopic determination of isotopes demands equally refined measurements. Modern spectroscopic methods are able to satisfy these demands.

Included in the work under review are sections devoted to: the principles and methods of spectroscopy, types of spectroscopes and of spectra, spectro-photography and photographic plates for same, spectro-photometry, spectral series and X-ray analysis. An adequate presentation of these subjects within the modest dimensions of the volume is impossible, and in our opinion were better left unattempted.

The author has "endeavoured to give as much information as space allows of the practical laboratory side of the subject . . . bibliographic notes have been supplied to enable the reader to seek further information." He will, we feel sure, agree with us that even in these broadcasting days too wide a field of reading is opened up to the reader who happens on the references, "Journ. Roentgen Soc.," or "University Press" on pp. 75 and 100 respectively. The following are noted among points in the book standing in need of revision:—The Rowland method of coincidences described on p. 15 is inaccurately given, and, moreover, it should be pointed out that wave lengths so determined need correction; resolving power is wrongly defined on p. 40 and wrongly calculated on p. 41; the angle determined by the method given on p. 47 is *twice* the prism angle; a grating is never mounted normal to the incident light by the trial and error method described on p. 50; angles are confused with their sines on p. 63; the method of use of the prism spectroscope given on this latter page leaves one wondering what one does if the third reading differs from the previous two; modern theory far from assuming "that lines in the spectrum are evidently due to wave-motions set up in the ether" (p. 65) has abolished the ether almost completely if not entirely, and contends that the lines originate in the analysing system, prism, grating, etc., just as a row of palings may convert a noise having no periodicity into a musical note; thoria is in part confused with ceria on p. 85; many substances have been dissolved in water since 1900, and one fails to recognise Hartley as a pontifical authority on the problem of solution (p. 150); the significance of Fig. 77 is far from clear; the expressions on p. 182 for the velocity of propagation of electro-magnetic disturbances are seriously in error. A number of minor inaccuracies has been noted on pp. 54, 75, 84, 181, 182. Interspersed through the book are portions dealing with photo-electricity, fluorescence and phosphorescence and the Zeeman effect. Scant justice is done to these. The reviewer would commend in the volume only Chap. VII., dealing with the manufacture of colour-sensitive plates. The author's connexion with the Research Laboratory of the Imperial Dry Plate Co., Ltd., gives an authority to this part of the book which is missing from the remainder. An authoritative work similar to Kayser's "Handbuch der Spectroscopie" is lacking in English scientific literature.

J. S. G. Thomas

Raw Materials for the Manufacture of Sulphuric Acid and the Manufacture of Sulphur Dioxide. *By* W. Wyld *Pp. xiii* + 558. *London: Guerney and Jackson*, 1923. *Price* 36*s*.

This is the first volume of the new edition of the late Prof. Lunge's classical work, "Sulphuric Acid and Alkali." Forty-four years have elapsed since the publication of the first edition in this country and in the present year of grace the chemical trade at home is celebrating the centenary of the alkali industry and the jubilee of the ammonia-soda process. Forty-four years ago the ammonia-soda process was in its infancy, the Leblanc process well established but still lacking the improvements and refinements attained in later years. The Leblanc process as a source of alkali has disappeared and the older methods of chlorine production have been replaced by electrolytic methods. In Lunge's several editions these changes and all they imply have been faithfully followed and Lunge's work has become an essential standard book of reference to a very wide circle.

The welcome to the new edition is sure to be hearty and congratulations are due to Dr. Cumming for his courage in undertaking his present task. In an appreciative editorial preface Dr. Cumming indicates the necessity for re-subdivision more in accord with modern developments; separate authors undertaking the special subject volumes. Notwithstanding the re-arrangement of the subject matter, the elimination of some that is old and the introduction of much that is new—and perhaps most of all the disappearance of the personal note—the new volume breathes the spirit of Lunge and still remains Lunge's work. Lunge's work, yes; but in improved form. Though the subject-matter index is still inadequate, the new setting out of the sub-headings makes the volume much more convenient for reference purposes and the transference of the numerous literature references to the bottom of the page renders the text much more readable. In the main the present volume covers the major part of the subjects dealt with in Volume 1

Part I, of the 1913 edition; Chapter V dealing with copper extraction, etc. is, however, based on material formerly appearing in Part III. In many cases where old subject matter remains the wording has been amended to suit the English idioms—at the same time, notwithstanding such alteration, the reviewer feels that the old wording caused him to make notes of important matter apparently omitted although such matter was subsequently found to be fully described in later pages.

Considering the contents in sequence, Chapter I deals with the history and general principles of the manufacture of sulphuric acid. Chapter II goes fully into the occurrence, properties and statistics of the various raw materials, such as sulphur, pyrites, zinc blende, etc., and concludes with the methods of supplying nitrogen oxides in the sulphuric-acid process. The literature references and statistics clearly show the large amount of new matter that has been introduced. Very striking figures indicating the growth of the sulphur industry in the United States are given on page 24, the production in 1921 amounting to 1,879,150 tons or nearly 80 times that in 1903 when the Frasch process began to receive serious general consideration. This large production, coupled with change of process, has had a marked effect on the vitriol industry and the final result of the competition between sulphur and pyrites cannot yet be foreseen.

On page 56 there is a repetition of matter appearing on page 13 under colloidal sulphur and it is not quite clear why the headings "Special Technical Forms of Sulphur" (pp. 56, 57) should be separated from those of "Commercial Descriptions" and "Uses of Sulphur" (pp. 18-19). On p. 61 under "Estimation of Arsenic" in sulphur it is stated that: "it (As_2S_3) occurs more especially in that recovered from alkali works"—this surely cannot refer to Chance sulphur, which was universally recognised as a product of remarkable purity in every respect. The statement on p. 123 under Coal-Brasses as to the non-injurious effect of carbon dioxide in vitriol manufacture should be noted and whilst the reviewer has not had experience to guide him at the same time he has never been able to understand or get any explanation as to why its presence should act prejudicially. In this connexion should not the reference on p. 143 to Chapter IX read Chapter IV? Probably the most interesting new matter in this chapter is contained in pp. 166-175 under supply of nitrogen oxides by oxidation of ammonia This subject is discussed in considerable detail, but it is difficult to understand the omission of any reference to the work of Imison and Russell published in this *Journal* (Feb. 28, 1922).

Chapter III (pp. 176-288) deals with "The Properties and Analysis of the technically employed Oxides of Sulphur." On p. 183 certain of Pellett's observations—perfectly true and probably needing emphasis in the original communication—appear superfluous to-day with our better understanding of vapour pressures The Knietsch curves for H_2SO_4—SO_3 (p. 198) deserve a more complete diagram; that given is merely qualitative, whereas to-day quantitative figures are wanted, especially of freezing (or melting) points. The specific gravity tables for sulphuric acid (pp. 203-205) have been recalculated by Dr. Cumming and are new; they occupy only half the space of the earlier tables and still contain all that is necessary for general work at home or abroad.

Under the action of sulphuric acid on metals the reviewer regrets absence of reference to his earlier work (*cf. J.*, 1903) on the action on platinum. Much new matter is given regarding the action on lead, but much still remains to be done before a satisfactory explanation of the varying life of the lead-chamber can be given The action on iron alloys (silicon iron) is discussed in two pages, and it is to be hoped that the merits and defects of these alloys will be more fully dealt with in the later volumes.

The older controversy relating to the part played by the oxides of nitrogen in vitriol manufacture has been much condensed and made more intelligible; discussion will probably continue so long as the chamber process exists.

Under Chapter IV, on the production of sulphur dioxide, the author deals with the crushing of pyrites and the burning of sulphur, pyrites, zinc blende, spent oxide, etc., and here one finds much new matter illustrated by new diagrams. The preparation of sulphur dioxide in pure or liquid state is also included, together with methods of dust removal and composition of burner gas. Several pages are devoted to electrical precipitation, but no reference is made to the results obtained in this country and published by McNab (*Ministry of Munitions Report*).

The final chapter embraces the briquetting and sintering of cinders and recovery of copper and other metals, etc. Much new matter is introduced here and the general change in methods of working is clearly indicated.

Many of the analyses quoted in this and earlier editions are old and not representative of modern conditions. In this respect an author's opportunities are limited; the average quality of a raw material or finished product is seldom advertised and published figures generally relate to odd samples or to a particular class of ore used in limited quantity in some particular works.

Printers errors are few in number; exception must, however, be taken to the word "volumetrical" and still more to "cuprous" as applied to pyrites containing copper. Cuprous to chemists has its own special meaning and hitherto home readers have only been acquainted with the word "cupreous" in the above connexion.

As in the earlier editions, patents practically stillborn are included whilst others actually operated for considerable periods are not evely quoted. All the same the volume clearly shows the trend of the industry and gives due prominence to the majority of the newer methods responsible for definite advance. More cannot be expected. J. T. Conroy

Die Polysaccharide. *By* Hans Pringsheim. *Second edition, revised. Pp. vi+234. Berlin: Julius Springer,* 1923. *Price, paper,* 7*s.* 6*d., bound* 9*s.*

So little information is available on the polysaccharides to the student of chemistry in the early stages of his work before he is in a position to consult original memoirs, that the publication of a work, now in its second edition, devoted specially to the subject, is a welcome addition to scientific literature. The explanation why no work has previously appeared on the subject is that it is of such a complex character that the workers themselves did not understand the true interpretation of the experimental data which they brought forward. They wrangled with one another, often over minor points. This state of affairs underwent a change when the "organic chemist" appeared on the scene. The subject has not, however, been divorced entirely from biochemistry, for the crisis dates from 1904, when Schardinger announced that he had obtained crystalline dextrins, by inoculating starch paste with a bacterium, *Bacillus macerans*. These dextrins were submitted to purely chemical diagnosis by the author of the present work. Pringsheim determined the molecular weights of the three crystalline dextrins obtained by Schardinger, and he showed that they were polymeric or co-ordination compounds, and that they could be reduced in molecular weight—depolymerised—by treatment with acetic anhydride and zinc chloride. Starch, cellulose and other polysaccharides appeared therefore to be polymeric or co-ordination compounds of some simple basal units. This work has been continued by Karrer, by Pictet, and by Irvine, and has thrown an entirely new light on one of the most intricate problems in chemistry.

The volume under consideration does not aim at being an exhaustive monograph. Indeed it is almost exclusively concerned with the subject from the time of Schardinger's work, although there is some mention of previous biochemical researches. The author deals with recent chemical work fairly completely, and we are glad to see that he has given credit to other workers who differ from his views in regard to the constitution of the polysaccharides. He mentions specially in his introduction the recent work of Irvine and his school, of Pictet, and of Karrer.

The author divides the fundamental units of the polysaccharides into four groups: The trehalose-, maltose- (copper reducing compounds), amylose- (ring compounds and glucosans), and anhydro-types (open chain compounds, glucans). Under the heading "Polysaccharides of the first order" are included lactose, maltose, sucrose, etc., and special attention is paid to the method of determining the constitution of these sugars by the methylation method first employed by Purdie and Irvine twenty years ago. Dealing with the synthesis of these sugars doubt is thrown on E. F. Armstrong's observation (1905) that maltose is produced by the action of emulsin on glucose, seeing that the enzyme in question does not hydrolyse maltose. It should be pointed out, however, that Armstrong was fully aware of this apparent anomaly. Pictet has claimed to have synthesised maltose by heating together the two glucosans and hydrolysing the resulting dextrin with oxalic acid.

The main portion of the work commences on page 50 and deals with what are termed polysaccharides of the second order, that is to say cellulose, starch, inulin, glycogen, pentosans, and nitrogenous bodies such as chitin.

One of the most interesting sections of the work is that devoted to the crystalline dextrins or polyamyloses with which the author's researches have been so closely connected. The bearing of this part of the subject on the constitution of starch is at present a matter of dispute between Pringsheim and Karrer. The latter holds the view that the basal unit of starch is anhydromaltose or diamylose. Pictet and Jahn have recently obtained an amorphous substance isomeric with the triamyloses, and as a result of this discovery Pringsheim is inclined to the view that the basal unit of starch is a triamylose. Irvine and his school, whose main studies are based on the methylation of polysaccharides, also put forward formulæ of the triamylose type as the basal unit of both starch and cellulose.

The author appears to have dealt with all the principal points in more recent literature on the subject, but the sequence in which these are discussed leaves much to be desired, since it is somewhat disconnected, in addition to which the diction is involved: we miss the lucid language on carbohydrate chemistry of Emil Fischer, and of Tollens. The work is remarkably free from typographical errors. It may be added in conclusion that chemists who are working on this involved branch of their subject cannot but feel grateful to the author for bringing together within a compass of a small volume an account of the extensive modern work, together with full references to the literature. Arthur R. Ling

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business in the Chemical trade is exceedingly quiet; there is no sign of any recovery to more normal conditions. Prices are well maintained and show but little tendency to fall; naturally at times like the present there will always be a certain weakness owing to the attempts of producers to keep manufacture going.

Acetic Acid, 40% tech.	£24 per ton. Still firm, but rather less inquiry.
Acid Hydrochloric	3s. 9d.-5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw.	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Demand steady, export inquiry good.
Arsenic (White)	About £71 per ton.
Bleaching Powder	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Business much below normal.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand.
Copper Sulphate	£27 per ton.
Potash Caustic	£33-£34 per ton. Little moving.
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Potass. Chlorate	3d. per lb. Very dull.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76%	£20-£21 per ton. Steady demand.
Soda Crystals	£5 5s.-£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£26 per ton. Very scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b London, 1-cwt iron drums included.
Sod. Chlorate	2¾d.-3d. per lb. Very dull.
Sod. Nitrate refd. 96%	£13 5s.-£13 10s. per ton ex Liverpool. Steady demand.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	£15-£16 per ton carr. paid. Very quiet. Prices unstable.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25-£29 per ton according to quantity.
Carbon Black	1s. 1½d.-1s. 3d. per lb. Ample supplies now coming forward.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood distillation products.

Acetate of Lime—	
Brown	£11-£11 5s. per ton. Dearer. Good steady demand.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8 5s. to £10 15s. per ton, according to locality of market and type of charcoal.
Iron Liquor	1s. 5d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	1s 3d. „ „ 14/15° Tw.
Wood Creosote	2s. 7d. „ „ Unrefined.
Wood Naphtha—	
Miscible	6s. 8d. „ „ 60% O.P. Market quiet.
Solvent	5s. 9d.-6s. per gall. 40% O.P. Demand increasing.
Wood Tar	£5-£6 10s. per ton, according to grade.
Brown Sugar of Lead	£42-£43 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d.-1s. 2½d. per lb. Increased demand in some directions due to lower prices now possible owing to reduction in Crude Carbolic price.
Crude 60's	3s.-3s. 3d. per gall. Fewer inquiries.
Acid Cresylic—97/99	2s.-2s. 5d. per gall. Steady demand.
Pale 95%	1s. 11d.-2s. 4d. per gall.
Dark	1s. 10d.-2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.

Anthracene Oil—	
Strained	8¾d.-11d. per gall. Supply short. Plenty of inquiries.
Unstrained	8¼d.-9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1¼d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.
Pure	2s. 1d.-2s. 2d. per gall.
Toluole—90%	1s. 9d.-2s. per gall. Weaker in sympathy with solvent naphtha.
Pure	2s.-2s. 5d. per gall. Not much inquiry.
Xylol	2s. 6d.-3s. 3d. per gall., according to quality. Good demand.
Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil	8d.-9½d. per gall. Market steady. Good demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	8¾d.-9d. per gall.
Solvent 90/160	1s. 6½d.-1s. 7d. per gall. Business quiet.
Solvent 90/190	1s. 6½d.-1s. 7½d. per gall. Market moderately active.
Naphthalene Crude—	
Drained Creosote Salts	£7-£8 per ton. Fair demand. Supply short.
Whizzed or hot pressed	£11-£14 per ton. Few inquiries.
Naphthalene—	
Crystals	£18 10s. per ton.
Flaked	£17 per ton.
Pitch, medium soft	132s. 6d.-140s. per ton. Autumn delivery. Numerous inquiries.
Pyridine—90/140	17s.-18s. per gall. Demand good.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Business in dyestuffs is moderately good. Depression in the textile trade continues, and until this improves there is not much chance of better business, at least in the home trade. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 6d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 9d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. 6d. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Markets are practically stagnant, and with foreign exchanges in violent fluctuation no improvement can be expected at present.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. 3d. per lb. for cwt. lots. This price would be shaded for large quantities.
Acid, Benzoic	2s. 6d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8¾d. per lb., less 5%. Business rather slack, but continuation of the hot weather should improve the market, as spot stocks are not large.
Acid, Gallic	3s. per lb. Down to 2s. 11d. for large quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 3d. per lb. Poor demand.
Acid, Tannic	3s. 6d. per lb.
Acid, Tartaric	1s. 4d. per lb. Demand improved on account of warmer weather.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 6d. per lb. Complete lack of demand.
Amidopyrin	12s. 6d. per lb. Now cheaper but demand still very poor.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. per oz. More active.
Barbitone	21s. per lb. Still maintained.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Unchanged. Continent still offering at low prices.
Calcium Lactate	2s. 6d. per lb. for best makes, which are not in too plentiful supply. Better demand.

Chloral Hydrate..	.. 3s. 9d. per lb., duty paid.
Chloroform ..	.. 2s. 2d. per lb. for cwt. lots. Higher prices are looked for in near future.
Creosote Carbonate	.. 8s. lb. Demand negligible.
Formaldehyde 40%	.. £90-£92 per ton. Very firm.
Guiacol Carbonate	.. 8s. 6d. per lb. Neglected.
Hexamine ..	.. 3s. 7d.-3s. 9d. per lb. Tendency rather weaker.
Homatropine Hydrobromida	.. 30s. per oz.
Iron Ammon. Citrate	.. 2s. 5d. per lb. for cwt. lots.
Magnesium Carbonate—	
Light Commercial	.. £37-£38 per ton net, according to quantity.
Magnesium Oxide—	
Light Commercial	.. £82 10s. per ton, less 2½%.
Heavy Commercial	.. £28 per ton, less 2½%.
Heavy Pure ..	.. 1s. 6d.-2s. per lb., according to quality.
Menthol	.. 40s. per lb. spot.
Methyl Salicylate	.. 2s. 4d. per lb. for carboys. Somewhat weaker.
Methyl Sulphonal	.. 15s. per lb.
Morphine ..	.. Makers have advanced all prices. Alkaloid—Cryst. 10s. 11d., Precip. 10s. 8d., Acetate 8s. 6d., Hydrochlor. 8s. 6d., Sulphate 8s. 6d. per oz.
Paraformaldehyde	.. 3s. 9d. per lb. Lifeless.
Paraldehyde ..	.. 1s. 6d. per lb. accepted for large orders. Slightly lower for forward delivery.
Phenacetin ..	.. 6s. 6d. per lb. More active than other pharmaceuticals.
Phenazone ..	.. 7s. per lb.
Phenolphthalein	.. 6s. 3d. per lb.
Potass. Bitartrate—99/100% (Cream of Tartar) ..	.. 96s.-98s. per cwt., less 2½%.
Potass. Ferricyanide	.. 3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide ..	.. 15s. 8d. per lb. Good demand. Steady market.
Potass. Permanganate	.. 10½d. per lb. for large quantities.
Quinine Sulphate	.. 2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin ..	.. 5s. 6d. per lb. Cheaper.
Salol	.. 2s. 9d. per lb.
Silver Proteinate	.. 10s. 6d. per lb.
Sod. Benzoate ..	.. 2s. 6d. per lb. Slow of sale.
Sod. Citrate ..	.. 2s. 2d. per lb. for B.P.C. 1923 quality in cwt. lots.
Sod. Hyposulphite—	
Photographic	.. £15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	.. 15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	.. 82s. 6d.-87s. 6d. per cwt. Fairly good demand. Expected to improve with continued warm weather.
Sod. Salicylate ..	.. Powder 2s. 7d. per lb., and Crystal at 2s. 9d. per lb. Less business.
Sod. Sulphite, anhydrous	£27 10s.-£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal ..	.. 14s. per lb.
Tartar Emetic ..	.. 1s. 2d.-1s. 4d. per lb.
Thymol	.. Better inquiry. 15s. 6d. per lb. for cwt. lots of natural recryst.

PERFUMERY CHEMICALS

Acetophenone ..	.. 10s. 6d. per lb.

TRADE NOTES

London Joint City and Midland Bank, Limited

The Directors of the London Joint City and Midland Bank, Limited, announce an interim dividend for the half-year ended June 30, last at the rate of 18 per cent. per annum less income tax, payable on July 14. The dividend for the corresponding period of 1922 was at the same rate.

Reeves & Sons, Ltd.

Messrs. Reeves & Sons, Ltd., Colourmakers, Dalston, have issued a directors' report and balance-sheet at April 30, 1923, with profit and loss account from May 1, 1922, to April 30, 1923, which shows a net profit of £20,142 4s. The directors recommend a dividend of 10 per cent. upon the Ordinary shares payable on July 13 next, carrying forward the balance to next account.

The report was adopted at a meeting of the company held on July 5.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JULY 20, 1923 No. 29

EDITORIAL

Our advertisement columns this week include a first preliminary list of the subscriptions to the Federal Council Fund. The list is at the moment a small one; times are not propitious for the collection of that large amount which is required for all the schemes and activities of the Federal Council. But such a time will come, and when it does the Federal Council will not hesitate to ask the large companies and the wealthy individuals for handsome gifts. However, a beginning has to be made. We understand that in the interim the Federal Council will go on begging for small sums until a capital of three or four or five thousand pounds is obtained, the income of which will more than suffice for its present needs and will enable a respectable amount to be set aside each year to be added to the capital. The Federal Council has no paid officials, no office expenses, not even two shillings per annum. No organisation carrying on important work can perform its duties more cheaply. It has already been useful to the chemical community, and we believe that it will steadily and quietly increase its influence and usefulness. When the time comes for the large schemes and the need for large sums an income of two or three hundred pounds will be very useful towards organising a thorough campaign on a large national scale. The Committee entrusted with the collection of the Fund includes representatives of all sorts and conditions in the chemical world, and consists of Sir William Pope, Dr. E. F. Armstrong, Mr. H. E. Coley, Mr. E. V. Evans, Mr. Emile Mond, Mr. W. J. U. Woolcock and Dr. S. Miall. We noticed in Dr. E. F. Armstrong's Presidential Address an appeal to chemists to support the Fund and a suggestion for a more extensive machinery for the collection of gifts in all parts of the kingdom, and we commend his eloquent words to the careful consideration of our readers.

The article, which appeared in our last week's issue, by Prof. Patterson on the "Refereeing of Scientific Papers" deals with a subject which, though it only appeals directly to a small percentage of the members of any Society, yet has a considerable indirect interest for all readers of scientific journals. The article leaves the impression that the majority of papers presented to Societies give rise to more or less serious friction between the author and Publication Committee. We hope and believe that this is only true of the small minority of papers. In the case of our own Society we can say with some authority that with only a very small portion of the papers submitted is there anything in the nature of controversy between author and Committee, and we should be sorry indeed if the opposite impression prevailed, for this would inevitably tend to check the supply of papers, especially from the younger and more sensitive authors. It should be realised that the object of the Publication Committee is to secure the dissemination of the truth, and nothing but the truth, in a form in which it can best be understood and assimilated. Authors who submit their papers to a Society for publication should feel assured that they will receive sympathetic consideration at the hands of the referee and of the Publication Committee. At the same time it is the duty of the Societies to the readers of their journals to get expert opinion on such papers. It is not, therefore, a light responsibility which is undertaken by the Publication Committees of the various Societies—to see that full justice is done to the author whilst adequate security is afforded to the reader. We might mention that Prof. Patterson's suggestion that author and referee should be put into communication with one another has in several instances been adopted by our Society, on the suggestion of the referee, and in each case the result has been eminently satisfactory.

ARTIFICIAL ABRASIVES

By M. BARRETT

The use of artificial abrasives in the engineering and allied trades is increasing very rapidly and the total amount consumed per annum now reaches an enormous total. For all practical purposes only two artificial abrasives are used industrially and these are silicon carbide, *i.e.*, Carborundum, and crystalline alumina, *i.e.*, Alundum. Unfortunately, neither of these materials is manufactured on any commercial scale in this country, and we are entirely dependent on foreign sources of supply, particularly from America. During the War this lack of a home supply occasioned, at one period, very great anxiety and necessitated the control of all existing supplies and the establishment of the Abrasives Department of the Ministry of Munitions.

Although adequate stocks are now available, at a price, it is difficult to understand why artificial abrasives are not manufactured in this country, having regard to the fact that the master patents controlling the production of both products have now expired, and ample data are available to ensure the successful technical production of both these products.

Both materials are electric-furnace products and there seems to be an impression that economic manufacture can only be carried out in countries provided with ample water power, and thus able to produce electrical energy cheaply. There is some justification for this belief in respect of silicon carbide, and it is probable that manufacture in this country would be somewhat speculative unless cheap energy was available from waste coke-oven or blast-furnace gases.

For silicon carbide the cost of electrical energy represents nearly 60 per cent. of the total cost of production, but this energy represents only eight per cent. of the total cost of producing crystalline alumina.

As raw materials we have everything required in abundance for manufacturing silicon carbide, but we have no workable deposits of suitable bauxite which is the sole raw material used in the manufacture of crystalline alumina. Very extensive deposits, however, exist in Ireland, and it is even possible that use might be made of the bauxitic clays recently discovered in Ayrshire. American bauxites, of suitable quality, it is curious to note, are scarce, and a considerable proportion of United States requirements is obtained from the Var district of France.

It is extraordinary that no attempt is made here to treat either the Irish or French bauxites and that we are willing to pay the cost involved in shipping raw material from France to America subjecting it there to a very simple process, and then shipping it back to this country. Prominent American electro-metallurgists of the writer's acquaintance have commented on this anomalous state of affiars and expressed surprise at the lack of enterprise and initiative in this country.

The aluminous type of abrasive is of much more general application and importance than the silicon carbide type ; in the United States six times as much of the former is manufactured as the latter, although the proportions were at one time reversed. This ratio difference is becoming more pronounced each year and there would appear to be little inducement, on that account alone, for the manufacture of silicon carbide to be taken up here. In case of need, however, both materials could be produced in one plant as the equipment necessary is practically the same for both products.

A conservative estimate of the total cost of producing the aluminous abrasive in this country, assuming that electrical energy would cost three times as much as it does in America, would not exceed 3d. per lb., and the current selling price is 10d. per lb. A market for the product is absolutely assured and there are even possibilities of an export trade being developed. The manufacturing process is simple in the extreme and relatively low capitalisation would be necessary. It is interesting to note that both abrasives are being manufactured in Germany, that country now being quite independent of America.

YOUR PENCIL UNMASKED

By F. COLIN SUTTON

In a recent criminal investigation much prominence was given to the matter of handwriting, and the question of forgery or of the authenticity of certain documents frequently arises. The type of communication most commonly under dispute is either typewriting or handwriting with pen and ink. In either of these instances it is a fairly simple matter to differentiate between the markings on any papers under examination.

The impressions made by different pencils, however, are not so easily distinguishable. Indeed, their comparison is reduced to a fairly exact science. Before explaining the methods employed it is necessary to give a brief historical survey of the development of the modern pencil. Prior to the discovery of graphite, which is known to chemists as an allotropic modification of carbon—another modification being the diamond—pencils were composed of metallic lead or alloys of lead which were cast into a convenient shape and wrapped in paper holders. Pencils of this type were in common use until late in the eighteenth century, and are not entirely unknown even at the present day. The metals composing the alloy were lead, tin and bismuth, and occasionally about one-sixteenth part of mercury was added to make these mixtures softer to use. About the year 1560 graphite was discovered at Borrowdale, and from that time until the latter half of the nineteenth century the "black lead" pencils used all over Europe were derived from the Cumberland mine.

The prepared blocks of graphite were 2¼in. square by 1in. in thickness and were sawn into strips 1-16in. wide. Three of these were placed in the groove of a piece of cedar-wood and the complementary half was glued into position, and with a blank end of ½ of an inch a pencil seven inches in length was produced. The different grades of pencils were made by choosing the graphite according to its degree of hardness or blackness. Sometimes the graphite was boiled in spermaceti oil before being sawn up, with the object of obtaining a substance which should be softer and give more uniform marks. The high price of this particular oil to-day inhibits its use in modern pencil manufacture. Signs of exhaustion were manifesting themselves in the Borrowdale mine about the year 1840. Various methods were tried of utilising the graphite dust. In the most successful of these methods the dust was subjected to a pressure of about 100 tons per sq. in. air being exhausted simultaneously from the press.

In 1869 the Cumberland mine ceased working and composite pencils came into common use. The modern method of pencil manufacture was originated by Conté, of Paris, in 1795. This process consisted of making a paste of finely elutriated clay and graphite and forcing it through discs in a cylinder so as to produce circular threads of pigment. These were dried, baked in a crucible, and glued into grooves in the prepared wooden holder. The hardness of the pencil depended upon the proportion of clay and the degree of baking. Various pigments, such as lampblack, sulphur and resin have been introduced, but lampblack is the pigment mainly used in the cheaper grades of pencil.

Under the microscope the difference in the character of the markings of old and modern pencils can readily be distinguished. Ordinary lead and some alloys of lead show a series of irregularly distributed patches, each lit up to the same degree, each patch being scored with regular striations. The marks made by pure graphite, if examined under the microscope with a strong side light, appear as irregular silvery strokes, entirely different in character from those of lead. The continuity of the striations affords a means of determining which of two crossing lines in pencil writing was made first. Moreover, the absence of striations in the two markings distinguishes definitely between pencil writing and a carbon copy. Differences in the character of the striations serve to distinguish different varieties or makes of pencil.

Some of the earliest pencil writings discoverable in the British Museum date back to the beginning of the sixteenth century. One such specimen consists of drawings of coats-of-arms in "Stowe's Arms of Ancient Nobilitie." Some of these drawings show the characteristics of graphite and some those of lead. The pencil writing in Hogarth's notebook is in a very rich graphite.

The avenues of escape open to the forger are still more narrowed down by the magic of the analytical chemist. The presence of mere traces of iron, titanium or chlorides are made to reveal themselves under his reagents. It is pretty to watch, say, the revelation of the presence of so rare an ingredient as titanium in the markings of a pencil by the development of a bright yellow colouration upon treatment with hydrochloric acid and hydrogen peroxide.

STABILITY OF CO-ORDINATION-COMPOUNDS

By Prof. T. MARTIN LOWRY, F.R.S.

1. Two Types of Co-ordination

The preceding articles of this series point clearly to the existence of two fundamentally distinct types of co-ordination. These may be distinguished provisionally as Centric Co-ordination and Cyclic Co-ordination.

(a) *In centric co-ordination* the fundamental factor is the grouping of a series of radicals or molecules around a metallic atom or ion, mainly with a view to completing the outer electron-shell of the metal. The co-ordinated groups therefore cover a wide range of different types, although the atoms which actually share electrons with the metal are usually of small atomic number, *e.g.*, oxygen or nitrogen. This type of co-ordination is present in the vast majority of the compounds studied by Werner.

(b) *In cyclic co-ordination* the fundamental factor is the linking up of a metallic kation with a multipolar anion, with a view to completing a conjugated ring system. The importance of ring-formation as a factor in promoting co-ordination was disclosed by Tschugæff in 1907; but most of the experimental work on this type of co-ordination has been done in recent years by Prof. Morgan and his colleagues. Morgan is also responsible for introducing the term "Chelate," derived from the great claw or "chela" of the lobster and other crustacea, to describe those "caliper-like groups which function as two associated units, and fasten on to the central metallic atom so as to produce heterocyclic rings" (*Trans. Chem. Soc.*, 1920, **117**, 1457 footnote).

2. Stability of Centric Co-ordination-Compounds

Although co-ordination complexes of this type are usually described as being held together by "subsidiary valencies," they are often more stable than chemical compounds of a more commonplace character in which only "principal valencies" come into play. This fact is illustrated in a dramatic way in the properties of purpureo-cobaltic chloride. The empirical formula, $CoCl_3,5NH_3$, of this compound is that of a tervalent chloride containing five molecules of "ammonia of crystallisation"; but the compound is remarkable in that only two-thirds of the chlorine can be precipitated by silver nitrate or displaced by cold sulphuric acid; still more remarkable is the fact that the "ammonia of crystallisation" is retained by the compound even whilst it is liberating fuming hydrochloric acid under the influence of strong sulphuric acid! Cases such as the above are so far typical that the common test for this type of co-ordination is that the co-ordinated molecules or radicals must be "*clustered round the metallic atom in such a way that their ordinary chemical reactions are wholly concealed.*" Thus the ferro- and ferri-cyanides, the cobalticyanides, cobaltinitrites and cobaltammines "show none of the simpler reactions by which ferrous and ferric salts, cobaltic salts, cyanides, nitrites and ammonia are commonly detected in solution."

These drastic conditions are fulfilled by many co-ordination-complexes in which the "nucleus" is a tervalent cobaltic atom, since in this case the conditions favourable to co-ordination appear to be developed to a maximum extent. But it is clear that there must be a descending order of stability in other metals; and experience shows that compounds, such as ferric acetate and ferric sulphocyanide, the co-ordination of which is vouched for by their colour, are ionisable in aqueous solutions. A similar statement may be made in reference to copper, which forms a wide range of deep-violet compounds with ammonia, Rochelle salt, etc. The co-ordinated character of these compounds is again vouched for by their colour; but the complexes are of such a low order of stability that the mere addition of hydrogen sulphide will bring about a complete precipitation of the metal.

3. STABILITY OF CYCLIC CO-ORDINATION-COMPOUNDS

In the case of cyclic co-ordination-compounds, two independent factors must be recognised as determining the stability of the complex, namely (*a*), the character of the chelate groups, in addition to (*b*) the character of the co-ordinating metal.

(*a*) In the footnote in which the term is first introduced, Prof. Morgan includes ethylene diamine as a chelate group; but it is doubtful whether this classification should be maintained, in view of the fact that this amine is able to form stable co-ordination-complexes only with metals of the extended transition-series, *e.g.*, from V to Ga, most of which are able to form precisely similar compounds with ammonia. In cases such as these the crab appears to be dead. The inability of the ring system to grip may be attributed to the fact that it is saturated and does not contain any double bonds. The introduction of a metallic ion between the two amino-groups does not therefore supply the missing link in a conjugated system; and the energy liberated in conjugation (to which Thiele attached so much importance, and which he even tried to calculate from thermochemical data) is not available as a factor in promoting co-ordination. For this reason, in defining "cyclic co-ordination," I should restrict the term to those cases in which the introduction of a metallic ion completes or extends a conjugated system, and therefore gives rise to an exothermic action, with a corresponding stimulus to the process of co-ordination. It is true that, even in cases such as that of ethylene diamine, where two co-ordinated radicals are joined by a saturated chain of atoms, the size of the ring is an important factor in determining the stability of the co-ordinated complex; but it is mainly a negative factor, since ring-formation does not decisively promote co-ordination, although the strain involved in forming a ring of 4 or 8, instead of 5 or 6, atoms may prevent the formation of a co-ordinated complex even when two independent univalent radicals would co-ordinate quite readily.

(*b*) Assuming, however, that the claw is by no means lifeless, the strength of its grip will depend on the character of the object which it holds and seeks to retain. Working on these lines, Morgan has established that lithium is pre-eminent amongst the alkali metals in the stability of the compounds which it forms with acetylacetone. Beryllium appears to enjoy a similar pre-eminence amongst the bivalent metals, and aluminium amongst the tervalent metals—the bivalent and tervalent metals of the transition series being excluded in each case, since their co-ordination-compounds are of the centric type and do not need a chelate group to stabilise them.* In general it appears that the lighter metals are more readily co-ordinated than their heavier homologues—just as if the claw could grasp a small object more firmly than a large one. This suggests that the more powerful chelate groups should be able to grasp a proton, giving rise to co-ordinated-compounds in which a hydrogen ion replaces the ion of a metal. This view has been discussed, and some of the more important applications are described, in a communication which I made to the Chemical Society on May 3 (this vol., p. 496), in the course of which I showed that hydrogen is not merely able to play a passive part in co-ordination, but may itself assume an active rôle, as in the case of potassium hydrofluoride,

---

* The complexes formed by acetylacetone with the tervalent ions Al''', Sc''', Ir''', V''', Cr''', Mn''', Fe''', Co''', are so stable that they can be distilled. This is also true in the case of some of the bivalent metallic ions; but the compounds formed by the univalent metals of the alkalis nearly all char when heated, in spite of their much smaller molecular weight. The sodium, potassium and calcium compounds not only char when heated, but are "unstable in solution or in a moist condition." (Morgan and Moss, *T.*, 1914, **105**, 189.)

$$KHF_2 \rightleftarrows \overset{+}{K} + \overset{-}{HF_2} \text{ or } \overset{+}{K}[H\cdot 2F]^-,$$

where the hydrogen ion holds together two fluorine ions in the complex $\overset{-}{F}\overset{+}{H}\overset{-}{F}$.

4. CO-ORDINATED RINGS CONTAINING SIX ATOMS

Tschugæff suggested that the formation of co-ordinated rings is governed by the same rules that prevail in ring-systems of the ordinary type. This leads to two important conclusions:—

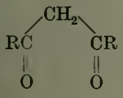
(*i*) That in saturated ring-systems a maximum of stability should be reached when the co-ordinated metal is associated with a chain of four other atoms to make a five-atom ring.

(*ii*) That in unsaturated or conjugated compounds a maximum of stability should be reached in a six-atom ring containing three pairs of conjugated atoms.

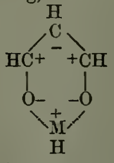
The conjugated six-atom ring-system is analogous to that of benzene, and compounds containing it may be expected to show some resemblance to aromatic compounds, not only in stability, but also in physical properties such as absorption spectra. The stability of the system is shown by the large number of cases in which the abnormal or exceptional properties of a compound may be attributed to the formation of a co-ordinated ring of this type; but the analogies in physical properties still await investigation.

Co-ordinated ring-systems are necessarily heterocyclic. Four principal types of conjugated rings can at once be recognised in the co-ordinated derivatives of β-diketones, of α-nitroketones, of α-cyanoketones acids and esters and of βγ unsaturated ketones, acids and esters respectively. These six-atom rings may be classified provisionally as follows:—

(i) *First type* (dioxonium ring)

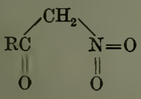


β-Diketone

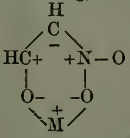


Simplest co-ordinated complex

(ii) *Second type* (nitroxonium ring)

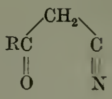


α-Nitroketone

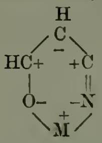


Simplest co-ordinated complex

(iii) *Third type* (cyanoxonium ring)

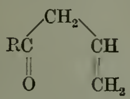


α-Cyanoketone

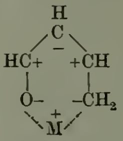


Simplest co-ordinated complex

(iv) *Fourth type* (carboxonium ring)



βγ-Unsaturated ketone

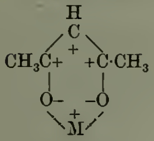


Simplest co-ordinated complex

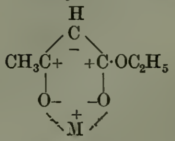
In each case the co-ordinated metallic compounds can be regarded as derived from a co-ordinated hydride or enol, isomeric with the original ketone. When, therefore, the nomenclature of co-ordinated ring-systems comes up for consideration, it will probably be convenient to name the hydrides as acids and the metallic-compounds as salts derived from them.

(i) *Examples of the first type* of conjugated six-atom ring are found in the co-ordinated derivatives of

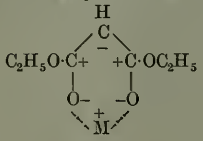
I *Acetylacetone*



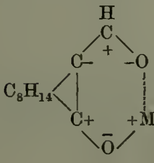
II. *Ethyl acetoacetate*



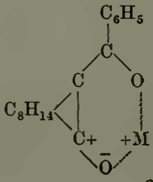
III. *Ethyl malonate*



IV *Hydroxymethylene-camphor**

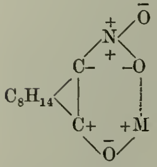


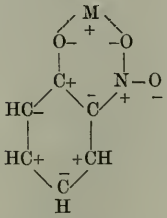
V *Benzoylcamphor**



(ii) *Examples of the second type* are found in the salts of

VI *Nitrocamphor** VII *Orthonitrophenol*

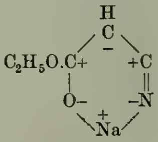




The yellow crystals of orthonitrophenol itself and the acidic dextrorotatory *pseudo*-nitrocamphor have probably the same co-ordinated structure as their metallic derivatives.

(iii) *An example of the third type* is probably found in

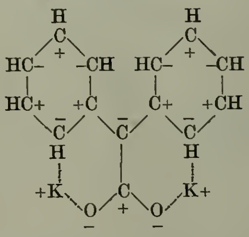
VIII *Ethyl sodio-cyanacetate*



In this case there has always been some ambiguity as to whether the sodium atom was attached to oxygen or to nitrogen; in the formula VIII it is represented as attached to both of these atoms.

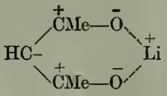
(iv) *An interesting example of the fourth type* is provided by diphenylacetic acid, a compound in which the tendency to enolisation appears to be developed more strongly than in any of the common carboxylic acids. In particular this compound is remarkable in forming a dipotassium derivative. It is suggested that this may be formulated as a doubly-co-ordinated complex IX containing two conjugated six-atom rings of the fourth type.

IX

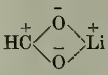


5. CO-ORDINATED RINGS WITH FOUR ATOMS

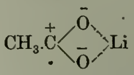
A completely-conjugated system can also be produced by the co-ordination of an ion with a chain of three other atoms, giving rise to a *four-atom* ring. The ordinary laws of ring-formation suggest, however, that such a system would be far less stable than a conjugated six-atom ring. This view is fully confirmed by experiment. Thus, although sodium derivatives are readily formed from bipolar anions, these are (apparently without exception) ionisable in solution. There is, indeed, quite a dramatic contrast between the behaviour of (i) the lithium derivatives of acetylacetone



and (ii) lithium formate or acetate,



or

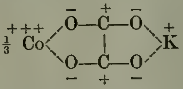


A comparison of the formulae shows that the peculiar properties of the acetylacetonate must be attributed to the replacement of $\overset{+}{\mathrm{C}}\mathrm{H}$ or $\overset{+}{\mathrm{C}}\mathrm{Me}$ by $\overset{+}{\mathrm{C}}\mathrm{Me}.\overset{-}{\mathrm{C}}\mathrm{H}.\overset{+}{\mathrm{C}}\mathrm{Me}$, *i.e.* to the change from a bipolar to a tripolar anion, whereby the ring-system is extended from 4 to 6 atoms. Whilst, therefore, we are bound to suppose that the salts of the carboxylic acids (when in the undissociated state or in a crystal) are co-ordinated, there is no difficulty in accounting for the fact that their aqueous solutions are always ionisable, except when the metallic ion is capable of developing centric co-ordination.

6. OTHER CO-ORDINATED RING-SYSTEMS

A ring containing an odd number of atoms must, if unsaturated, contain either (i) a saturated group which interrupts the conjugation, or (ii) a system involving crossed polarities. Odd-numbered rings are, however, quite common amongst co-ordinated-compounds, and under some conditions may possess definite chelate properties. Two examples of this kind may be quoted.

(a) *The oxalates.* The co-ordinated oxalates have already been formulated as containing two five-atom rings, thus

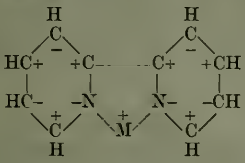


In both rings the conjugation is interrupted by two consecutive carbon atoms each carrying a positive charge. The addition of two metallic ions to the oxalate radical has, however, the effect of completing a more extensive conjugated system containing not less than *eight* alternately-polarised atoms. In these circumstances, the five-atom rings, in spite of the presence of crossed polarities in the centre of the system, appear to possess powers of co-ordination comparable with those of a four-atom conjugated system, although very much inferior to those of the conjugated system of six atoms described in section 4 above. The influence of centric co-ordination is, of course, shown in the stability of the cobaltic complex in the formula set out above, as compared with the ready ionisation of the potassium.

---

* These camphor compounds can be written most conveniently with the ion M in the position usually assigned to the nitrogen atom in *iso*-quinoline; but the co-ordinated ring is exactly the same as in the other cases.

(b) *Dipyridyl.* The dipyridyl molecule differs from that of ethylene-diamine in virtue of the two conjugated aromatic rings which it contains. Although the polarities of these rings are crossed at the point of union, a concordant system of conjugation is produced throughout the rest of the molecule when a metallic ion is co-ordinated between the two negatively-charged nitrogen atoms



The added stability produced by the conjugation of the dipyridyl group affords an explanation of the fact that Werner was able to resolve the compound $\left[\overset{++}{\mathrm{Fe.3Dip}}\right]^{--}\mathrm{Cl}_2$, where the corresponding derivative of ethylenediamine does not appear to have been sufficiently stable for this resolution to be effected.

7. Summary

(a) Two types of co-ordination are distinguished, namely (i) *centric co-ordination*, in which the principal factor is the formation of a shell of electrons round a metallic atom, and (ii) *cyclic co-ordination*, in which the principal factor is the development or completion of a conjugated ring-system by the insertion of a metallic ion. (b) The stability of centric co-ordination-complexes depends mainly on the nature of the central atom of metal and appears to reach a maximum in the tervalent cobaltic ion. (c) The stability of a cyclic co-ordination-complex depends on the nature of the conjugated ring-system as well as on the nature of the metallic ion. (d) A maximum of stability is reached in conjugated six-atom rings, the polarities of which are identical with those of aromatic compounds. (e) Conjugated four-atom rings are less stable, and the co-ordinated metal is usually ionisable in solution. (f) In the more stable cyclic systems a proton can take the place of the metallic ion and yield co-ordinated complexes.

OBSERVATIONS BY "EYE-WITNESS"

The Annual Report

of the Association of British Chemical Manufacturers was described by its Chairman at the Annual Meeting last week as a fair microcosm of the work of that Association. Considering it on that plane, it certainly gives a basis for the generally high reputation to which the work of this body has attained. To be really successful it must justify its existence to its members, to the Government and to the nation, and be useful to each in turn. The individual members probably consider its work on Alcohol, Railway Rates, Statistics and Legal Matters to be of such direct usefulness as to be obviously worth the annual subscription. The Government is possibly not unmindful of the advantage of having an Association which can be referred to for advice on any matter affecting the industry, and which has helped very judiciously in the administration of such tiresome pieces of legislation as the Dyestuffs Act and the Safeguarding of Industries Act. And if—which Heaven forbid !—we were ever landed in another war I can well imagine with what relief the Government would turn to the Association and ask for and receive the fullest possible assistance in chemical production. For whatever our pundits may say, methods of warfare have a habit of commencing in a new war just where they left off in the old one.

To the Nation

its usefulness must consist in a steady and regular representation to the world of the progress of the industry in this country. There are many ways of doing this, and but few of them are unused by the Association of British Chemical Manufacturers. It is a counterpart of our own Society ; its relation to the industry is what our relation should be to the science, and I can quite understand Sir Max Muspratt's kindly references to *Chemistry and Industry.* The policies of the Society and of the Association are identical. I have tried to think of some form of national publicity which chemical industry has not yet adopted. Newspaper articles, letters to the Press, and public dinners have become common form. Fairs and Exhibitions are a matter of routine. The art of pamphleteering has been revived. Cinematograph films illustrating the various branches of chemical work are in course of preparation. Only sky-writing has been overlooked ! But the Chairman of the Association of British Chemical Manufacturers has a complaint. It appears that the Council have made arrangements so that any new developments in a member's works—by which, I suppose, is meant any new or improved products—can be notified in even the furthest quarters of the globe, and the members will not use the machinery provided. Well, well! The chemical industrialists are only human, after all.

Alcohol

It seemed fitting that a time when we are all cutting down our consumption of alcohol on account of the heat should be chosen for the announcement of the conclusion of the negotiations between the Association and the Board of Customs and Excise. In substance I understand that what has been arranged is this :—It will be possible to use duty free spirits in the preparation of fine chemicals in which the alcohol radicle enters as part of the final product, if no alcohol, as such, remains in the final product and various other requirements are complied with. In approved cases where industrial methylated spirits are unsuitable and pure methyl alcohol involves some material disadvantage, it may be possible to use ethyl alcohol denatured with 2 per cent. of pure methyl alcohol. This should go some way in assisting British Chemical Industry to overcome the advantage which the industry in other countries has had through cheaper alcohol, but it by no means solves the problem. Each year, however, I think we get a little nearer it; every failure teaches us something.

All the Space

in the Chemical Section of the British Empire Exhibition has now been allotted, and I hear the number of complaints is very few considering that everybody cannot have a front-row position. The promptness with which anyone who was dissatisfied was offered their deposit money back indicates that a number of firms for whom room could not be found are quite prepared to take up any space which may be vacated. The pure science side is now on a satisfactory basis. I understand there is a Committee of the Royal Society, on which Mr. Woolcock has been given a seat, which will organise the scientific exhibit other than the pure chemistry part ; and that Sir Herbert Jackson, from the Royal Society Committee, will become a member of the Committee formed from the other learned bodies and the Association of British Chemical Manufacturers which is organising the pure chemistry exhibit. In this way it is hoped to prevent entirely any overlapping. The question of funds now seems to have been settled, and, while it would be an exaggeration to call them ample, there is sufficient for the Empire to make a good show. With only eight months before the Exhibition opens, and one of those a holiday month, I think we ought to know a little more about the character of the scientific exhibits. For example, did that wonderful lecture of Dr. Aston's at the Cambridge meeting of the Society give the promoters any ideas ?

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on Thursday, July 12, 1923, when the following were elected as the officers of the Association for the ensuing year :—President : R. G. Perry, Esq. Vice-Presidents : Sir John Brunner, Bt. ; Dr. Charles Carpenter. Chairman : Sir Max Muspratt, Bt. Vice-Chairman : Sir William Pearce. Honorary Treasurer : C. A. Hill, Esq.

In connection with the new Chair of Chemical Engineering at University College, London, a sub-committee for chemical engineering has been set up, and Sir John Brunner was appointed to represent the Association on it.

The General Manager reported that a Committee had been set up by the Minister of Health to inquire into the use of preservatives and colouring matter in food, and it was agreed that the Association should prepare evidence for submission to that Committee.

Among other matters discussed by the Council were the concessions which have been granted by the Customs Authorities in connection with the use of alcohol, which should prove of advantage to chemical industry.

CORRESPONDENCE

BIOCHEMICAL ACTION OF POLARISED LIGHT

Sir,—I am exceedingly interested in your correspondent Mr. E. G. Bryant's letter in the *Journal of Chemistry and Industry* of July 6. It would seem that he has not seen my letter in *Nature* (Vol. III, p. 49, 1923), in which I described the results I had obtained on investigation of the striking action of moonlight and of plane polarised light on the germination of seeds, and of polarised light on the hydrolysis of starch grains by enzymes.

My investigations have extended over the last two years, and they leave no doubt of the reality of the phenomenon mentioned by Mr. Bryant—namely, that certain biochemical reactions are definitely stimulated more by plane polarised light than by heterogeneous light of the same intensity. I may add that I am at present carrying out further work in conjunction with Prof. Baly at this University. Although my new experiments are not sufficiently advanced to publish the results, yet the observations made seem to be of great promise. Mr. Bryant has added one more to the long list of phenomena which can be explained by the action of polarised light—namely, the putrefaction of fish—and thus he has given support to the general theory I formulated in my letter to *Nature.* I may add, in conclusion, that I hope to communicate my results to Section B at the meeting of the British Association in September next.—I am, Sir, &c., E. Sidney Semmens.

The University of Liverpool,
July 17, 1923

FORTHCOMING EVENTS

Sept. 10–13. THE INSTITUTE OF METALS. Annual Autumn Meeting, to be held in Manchester. "The Use of Non-Ferrous Metals in Engineering," by Lieut.-Colonel Henry Fowler. Tickets are obtainable from Mr. G. Shaw Scott, M.Sc., 36, Victoria Street, S.W. 1.

Sept. 12–19. The British Association for the Advancement of Science. Ninety-first Annual Meeting, Liverpool. Among the papers to be read are the following:—(1) "The Electrical Structure of Matter" (Presidential Address), by Prof. Sir E. Rutherford, F.R.S. (2) "The Origin of Spectra," by Prof. J. C. McLennan, F.R.S. (3) "The Physical Chemistry of Interfaces," by Prof. F. G. Donnan, C.B.E., F.R.S. (4) "The Position and Opportunity of the British Empire," by Dr. V. Cornish. (5) "Unemployment and Population," by Sir W. H. Beveridge, K.C.B. (6) "Transport and its Indebtedness to Science," by Sir H. Fowler, K.B.E. (7) "The Education of Demos," by Prof. T. P. Nunn. (8) "Science and the Agricultural Crisis," by Dr. C. Crowther.

Membership Fees, £1 and upwards. Students' Tickets, for duly qualified persons, 10s. Full particulars can be obtained from the Secretary, British Association, Burlington House, London, W. 1, or from Local Hon. Secs., British Association, Manesty Buildings, College Lane, Liverpool.

PERSONALIA

Monsieur André Nicou, General Manager of the Micheville Steel Works, has been appointed Professor of Iron and Steel Technology at the National School of Mines in Paris. The same School has nominated Monsieur A. Cornu Thénard, Director of the Technical Works of the Cie. des Forges de Chatillon, to be Professor of General Metallurgy, and Monsieur J. Loiret, Engineer-in-Chief, of the Mines, to be Professor of Legislation.

FERTILISERS AND FEEDINGSTUFFS ACT

The Minister of Agriculture recently stated that he was aware that county councils were prohibited from instituting proceedings against offenders under the Fertilisers and Feedingstuffs Act, 1906, unless the Ministry gave its consent. Steps were being taken to appoint a Departmental Committee to enquire into the working of the Act and to report if and what amendments were desirable.—(June 28.)

NEWS AND NOTES

UNITED STATES

The Mangrove Industry

The Mangrove bark constitutes one of the world's most important sources of tannin because of its great abundance, wide distribution, rapid growth and comparatively low cost.

Various species of mangrove are utilised as a source of tannin, which is contained in all parts of the tree, more especially in the bark and leaves. The average content of tannin in commercial grades of bark is about 35 per cent. Care has to be taken not to expose the bark to moisture after collection, otherwise the tannin is lost. For this reason it is desirable to manufacture a tannin extract in the producing countries, although this has not yet been done to the same extent as with quebracho in South America. Although mangroves are found on most tropical coasts industrial utilisation has been developed on a large scale only in Colombia, East Africa, Madagascar, Borneo and the Straits Settlements.

The best grades of mangrove extract come from East Africa and Borneo, the tannin content ranging from 48 to 72 per cent. Used alone the extract yields a good pliant, workable leather, but of undesirable colour. To obviate this the tanners blend it with other tannin materials, such as myrobalan, valonia, sumac, and mimosa.—(*U.S. Com. Rep., May* 28, 1923).

Abrasive Materials in 1921

Natural abrasives were produced in 26 States in 1921, the chief centres of production being: Alabama, North Carolina, New Hampshire, New York, Virginia, millstones; Arkansas, Indiana, Ohio, oilstones; California, Connecticut, Maryland, Nevada, New York, Oregon, Utah, Washington, Diatomaceous (infusorial) earth; Illinois, Missouri, Oklahoma, tripoli; Indiana, rubbing stones; Kansas, California, Nebraska, pumice; Kentucky, hones; Michigan, Ohio, West Virginia, grindstones; California, Minnesota, Nevada, grinding pebbles; New Hampshire, New York, garnet; New York, Virginia, emery; Ohio, West Virginia, pulpstones; Ohio, Vermont, scythestones; Pennsylvania, rottenstone. Sales during 1920 and 1921 were valued at $4,299,812 and $2,707,366 respectively; production of all these abrasives has gradually declined. Values of sales, imports, exports, and apparent consumption in the United States in 1920 and 1921 were as follows:—

	1920.	1921.
Natural abrasives (sales)	$4,299,812	$2,707,366
Artificial „ (sales)	7,492,164	1,996,147
Imports	4,425,409	1,177,400
Total	16,217,385	5,880.913
Exports	7,025,621	3,320,590
Apparent consumption	9,191,764	2,560,323

Three different kinds of artificial abrasives are manufactured in the United States:—(1) Metallic abrasives, made by the Pittsburgh Crushed Steel Co.; and the Globe-Iron-Crush and Shot Co.; (2) Silicon carbides, manufactured by the Carborundum Co.; the Norton Co. and the Exolon Co.; (3) Aluminium oxides made by the Norton Co., the Carborundum Co., the Exolon Co., the National Abrasive Co., and the General Abrasives Co. (Inc.). In 1920 the value and production of artificial abrasives amounted to $7,492,164 (84,874,000 pounds), and in 1921 $1,996,147 (26,398,000 pounds).—(*Cf. J.*, 1922, 80 *R.*; *U.S. Geol. Surv., June* 15, 1922.)

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Reparation Dyestuffs

Sir P. Lloyd-Greame, in reply to Major Attlee, said that he was not aware that the British Dyestuffs Corporation charged 10 per cent. commission on reparation dyestuffs, and referred to an answer which he gave on this subject on December 4 last, to the effect that the Corporation received a commission of 6½ per cent. on the actual turnover, plus a further 1 per cent. for guaranteeing accounts, and a grant, which was limited in amount, towards the charges which they incurred relating to the importation of the dyestuffs. The Central Importing Agency undertook the duty of importing and distributing the dyestuffs for a commission of 3½ per cent., to be adjusted if prices fell, but this charge proved to be inadequate, and was considerably increased, with the approval of the Treasury, by various allowances made to the Central Importing Agency upon the final adjustment of their accounts.

Answering Major Attlee's further inquiries as to whether he was aware of the high prices charged for reparation dyestuffs by the British Dyestuffs Corporation, Ltd.; that the price of diamine fast yellow F.F., a dye for which there is no satisfactory British substitute, had been increased from 4s. per lb. to 7s. 6d. per lb. and to 10s. per lb., although this dye could be imported from Germany for 4s. 6d. per lb.; and of the discontent aroused by this action among colour users, Sir P. Lloyd-Greame said that no complaint as to the price of this dyestuff had been received by the Board of Trade, but arrangements were being reconsidered as to the pricing of reparation dyes, and the price of this particular dye would come under review. He also said that it was not a fact that these very high prices were put on in order to enable the Corporation to foist inferior substitutes on the colour users.—*July* 10.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for July* 5 *and* 12)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia	Chemists' and druggists' supplies	1
Belgium	Shoe leather	13
British India	Paint, oil, glass, glassware, rubber goods	5
Canada	Leather goods	7784/E.D./M.C./2
,,	Electric steel castings	*
Egypt	Ironware, building materials	22
New Zealand	Steel rails, joists	9
Norway	Leather for clothing	17
Rumania	Tubes, fittings (tender)	11017/F.E./E.C.
Sweden	Rubber mats	20
United States	Steel and iron pipe	25
Belgium	Shellac and chemical products	31
,,	Stearine, talc, carnauba wax, petroleum jelly, oils, lime carbonate, calcined magnesite	35
Canada	Copper and zinc plates	*
Czechoslovakia	Chemicals	37
Denmark	Agar agar	38
Netherlands	Perfumery, soap	45
Norway	Leather	48
,,	Tinplate	50
United States	Pyridine, ammonium carbonate, castor oil, tartaric and citric acid, naphthalene	20039/F.W./C.C.2
Uruguay	Electrical accessories (tender)	8279/F.L./C.C.2

* Canadian Government Trade Commissioner's Office, 73, Basinghall Street, London, E.C. 2.

TARIFF CUSTOMS EXCISE

Australia.—The exportation of leather is prohibited, unless it has been certified fit for export by a qualified officer.

British India.—Raw rubber is exempted from import duty.

Canada.—Revised import duties have been provided on firebrick and artificial silk.

New Zealand.—Inorganic acids, crude oils and greases are now duty free.

Poland.—The exportation of raw hides has been prohibited.

REVIEWS

Special Steels. *A concise treatise on the constitution, manufacture, working, heat treatment, and applications of alloy steels. By* T. H. Burnham, B.Sc. *Pp. xxi*+185. *London : Sir Isaac Pitman and Sons, Ltd.*, 1923. *Price* 5*s. net.*

The series of manuals of which "Special Steel," by T. H. Burnham, is one volume is stated by the publishers (Pitmans) to treat technology in a practical manner and to provide the student with a handy survey of the subject, which will be invaluable to the busy practical man who has not time for more elaborate treatises. Mr. Burnham has endeavoured to attain this result in regard to special steels by preparing a volume in which the subject-matter can be divided definitely into two parts, though in the book they are not separated. The greater part of the book is devoted to Sir Robert Hadfield's very numerous publications. The lesser part of the book contains the author's own views and the fruits of his studies in the literature.

It is noted largely on the title page and elsewhere that this book is founded on the researches published by Sir Robert Hadfield. The author's aim appears to have been to devise his chapters in such a way as to include the greatest possible number of Sir Robert Hadfield's publications. Occasionally this involves some violence to the appropriate subject-matter—as, for instance, where Sir Robert's lecture on the Metallurgical Chemist is dragged into the chapter entitled "Importance of Iron and Special Steels." The extreme prominence given to the work of one metallurgist in a book of this kind may be justified in some ways, but it is doubtful whether such a method is the best for a book which has the objects avowed for it by the publishers. The busy practical man does not want theoretical papers or repeated references to a single man's work. He wants explanations and applications, and well digested summaries of all the reliable work on the topics discussed. Unfortunately he is not very likely to find such information in this book.

The author's own contributions to the book are admirably described by himself in the opening words of Chapter II, where it is stated that, "In spite of all that has been written about iron and steel, many hazy notions regarding these still exist." Throughout his chapters the author has very little definite information to provide. His statements on the alloy steels are rather vague and on the slightest pretext he appears to turn with relief to safe ground and to quote Sir Robert Hadfield. Throughout the book the author fails to indicate those essential differences between the alloy steels and the carbon steels, which are of such great importance to the practical reader for whom the book is avowedly written. The simple example of the effect of mass during hardening, which is of such importance in this connexion, does not appear to be dealt with at all.

The book devotes a chapter each to steels containing the special elements, nickel, chromium, silicon, manganese and tungsten, and to nickel chromium steel and high speed steels. The general method of consideration is based upon the "Guillet" diagram, where available, for the particular systems. The treatment of the steels on this basis is accompanied by a general review of the mechanical properties of the steels and some still more general remarks on the method of manufacture. The balance of the chapters are provided by extracts from Sir Robert Hadfield's papers. These extracts have the merit of providing accurate information, but the author's own contributions are lacking in precision. This may be the effect of the very severe compression of the subject. Nevertheless it seems that a better treatment of the subject could have been achieved, starting from the same basis of Sir Robert's publications. The compression has led the author to give false impressions. Occasionally his statements are frankly incorrect, as, for instance, where he says, on page 54, that nickel steels have a fatigue resistance that is six time that of carbon steel.

The book is illustrated mainly by photographs of plant in Messrs. Hadfield's works and of the products of the same firm. Sir Robert Hadfield contributes an introduction to the book, and in an appendix of sixteen pages a complete list of his publications is provided.

L. Aitchisom

Absorption of Nitrous Gases. *By* H. W. Webb, M.Sc., F.I.C. *Pp. viii*+372. *London : Edward Arnold & Co.*, 1923. *Price* 25*s.*

The loss of fixed nitrogen in absorption plants has received inadequate treatment or attention in the literature mainly because practical experience was in the possession of few writers and partly because prior to the war the subject had not attained that importance with which munition and fixation plant has since invested it. Loss of nitre in sulphuric acid plants was perhaps an exception, and nitric acid plants using nitrate of soda were reasonably well served, but wherever the recovery of nitrous gases was the main object of an industrial operation, data and collaboration have been conspicuous by their absence. The author has therefore rendered a service in bringing together in logical and readable form the accumulated experience of the last decade.

The nine chapters deal with Properties of Oxides of Nitrogen; Theoretical Problems of Absorption; Construction of and Filling Material for Absorption Towers; Gas Circulation and Measurement; Handling of Acid; Concentration; Synthetic Production and Analytical Control. With regard to theoretical matter the book is comprehensive and affords a useful collection of all the more important work upon the oxides of nitrogen. In one or two places the subject might have been expanded with advantage. Fuller accounts might have been included of the paper by Donnan and Irvine Masson (not Irvine as stated), and that by Todd in the *Phil. Mag.* These two mathematical treatments of the oxidation and absorption of nitric oxide and nitrogen peroxide respectively have probably done more to remove empiricism in tower practice than any others, and deserve more than a passing reference to the original papers.

It is to be regretted that the author did not have access to the work of the Munitions Inventions Department, which settled such points as the preparation of nitrogen tetroxide by the action of nitric acid on nitrogen trioxide in the presence of a water absorber, being merely the back reaction of that reversible reaction occurring on absorption of nitrogen dioxide in towers, and that if this reaction was drawn to completion by oxidation in the liquid phase 80–90 per cent. nitric acid could be obtained. In a subsequent edition one may hope that the author and the publishers will be able to include full details of all relevant work done at University College.

Turning to the practical side, it is clear that the book will be of value not only to nitric acid technologists, but also to those dealing with absorption problems generally. The illustrations, diagrams and graphs are unusually clear and usable, and very little relevant matter has been omitted. Due prominence has been given to the importance of free space and to the other factors which bear on the relative values of the different types of filling material, but some of the figures quoted as to available scrubbing surface, etc. are inaccurate or out of date. Reference should have been made to Parrish's figures (*cf. Gas World*, Coking Section, July 6 and August 3, 1918), to intermittent flushing as against continuous circulation of liquid, and to the importance of uniform and correct distribution of gas as well as of liquid. The fallacy that gas and liquid must invariably meet on the countercurrent principle still persists. There is no reason why nitrous gases should not pass alternately up and down the towers of a series. In fact with parallel flow the time of contact is increased and the unsightly diagonal pipe lines disappear. Having regard to the very low gas velocity dictated by the time factor, "whirling" by means of spirals or the like seems a misnomer, and experience shows that a continual and considerable change of section or velocity and of direction is of primary importance. The author is misinformed in regard to Krupp's nitric acid pumps (p. 86), these being of V2A, a low-carbon nickel-chromium steel. On p. 196 the author states that a filling material with horizontal grooves will "channel" if not set accurately level. A suitable trial would surprise him and show that theory and practice do not tally on this point.

The chapter on analytical control is almost too complete and the author might be more critical to enable a choice to be made of a method most suitable for a given set of circumstances. A few selected methods fully described and criticised would have been preferable. In describing the reduction by Devarda's alloy, it is not stated when the alloy is to be added. The solubility of nitric oxide in sulphuric acid is repeated from the first chapter, and for the sake of scientific exactitude "titanous sulphate," etc. would be better than "titanium sulphate," especially as we are given the full structural formula of nitron. Considering that the author is practically breaking new ground, there is surprisingly little scope for criticism, and such details do not detract from the utility of the work, which is of a high order, and can be confidently recommended for use in industrial undertakings. C. J. Goodwin

Elements of Glass Blowing. *By* H. P. Waran. *Pp.* 113. *London: Messrs. G. Bell and Sons*, 1923. *Price* 2s. 4*d*.

Some knowledge of the methods of working glass in the blowpipe flame, and some skill in glass blowing are at last being recognised as acquisitions of great importance to science students, and general laboratory workers. To those engaged on research work, such acquisitions are of paramount importance, as the skill with which glass apparatus is made or repaired, often determines the success or failure of an experiment. It is therefore a matter for regret that glass blowing does not receive sufficient attention in the training of most of our science students, and that it has not yet found a permanent place in the curricula of our pure and applied science departments and colleges. Unfortunately, this lack of instruction in the art of glass blowing is not compensated by a good supply of reliable text books, for such books as are available in the English language are very few, and are anything but exhaustive in their treatment of the subject.

The present book is a welcome addition to this literature and compares very favourably with the best of the earlier books. It is written not for the professional glass blower but for the student, and the blowpipe, bellows and tools which are described, are such as may be found in most laboratories, but are very seldom used by up-to-date professional workers. The book is not exhaustive, and appears to have a bias towards apparatus such as is used in modern physical work, and especially towards what is termed "vacuum technology."

The subjects discussed are treated in a very practical manner, and details are given of how to perform the necessary operations; for more complex pieces of apparatus, details of the order of making and assembling the various parts are given. Throughout the book there are excellent explanatory drawings, illustrating the various exercises and showing the different stages from the original length of glass tube to the finished article. Such details and drawings will be found very useful to the student who sets out to obtain some knowledge of the subject without the aid of an instructor.

Though the treatment of each exercise is in general such as a student would require, the arrangement of these exercises is by no means so satisfactory. The drawing-down of a tube to form a tube of less diameter or to serve as a handle may well serve as a first exercise, but it is open to criticism to include in the second exercise on the bending of tubes, the making of nicely rounded U tubes, especially if light wall, wide bore tubing is to be used. The satisfactory making of such U tubes requires either a blowpipe different from the one shown on page 3, or the "gathering up" of a considerable amount of glass into the form of a thick walled elongated bulb, prior to the drawing and bending operation, and this requires skilled handling. A similar marked increase in skill is required to cope with the work of the third section of the second chapter, namely, the making of spirals. Again, after dealing with the making of joints of various types, such as T joints, internal junctions, and the making of complete circuits of tube, a chapter is devoted to the blowing of bulbs (1) at the end of a stem, and (2) in the middle of a tube. The whole of this chapter should come before the one on joints for two reasons: (1) The exercises in it are easier than most kinds of joints, and (2) the skill necessary to control and blow glass into small bulbs with uniformly thick walls is the basis on which neat junctions are made. In chapter VI the making of a thistle funnel is followed almost immediately by the making of glass stopcocks with hollow keys; the former is one of the easier things a student has to make, whilst the latter is one of the most difficult pieces of glassware to make satisfactorily. A student working from this book without the assistance of an instructor, would therefore find it difficult to select exercises of gradually increasing difficulty, so as to develop progressively his own skill in handling and blowing glass.

The last chapter of the book on "Commercial Methods for Laboratory Glassware" is evidently written from information obtained by brief visits to glass works, and unfortunately is very unreliable in many details. In this chapter it is easy to pick out a dozen errors or misstatements relative to the manufacture of glass, which to a certain extent are excusable, but one is exceedingly surprised when the author says on page 106, that the broad dark bands which are observed on examining glassware between crossed Nicols may "be coloured in the case of seriously strained pieces of glass." Surely he means the light areas may become coloured when the glass is subjected to severe stresses.

S. ENGLISH

THE ATOMIC THEORY IN 1921. *By* JAMES MOIR, D.Sc., F.R.S.S.A., F.I.C., F.C.S. *Reprinted from the "South African Journal of Science," Vol. XVIII, Nos.* 1 *and* 2, *pp.* 47–62, *December*, 1921. *Johannesburg: The S.A. Association for the Advancement of Science*, 1921.

Dr. Moir's Presidential Address to the South African Association for the Advancement of Science takes the form of a review of modern theories of atomic structure. This review is not by any means a mere recapitulation of current theories, but is impregnated with methods of interpretation that are the product of the author's own hard thinking on a difficult subject. In the main he appears to follow Kossel rather than Langmuir or Bohr, since he formulates hydrogen gas as composed of positive and negative hydrogen ions held together only by electrostatic attraction, so that the non-polar bond is practically suppressed. He also treats the hydrogen ion as identical with the hydrogen nucleus, and describes it as the cause of acidity, although it is well-known that this acidity is usually developed only in the presence of water; there is therefore very little justification for identifying the naked proton with the hydrogen ion of aqueous solutions, and still less for asserting that the size of the hydrion is somewhat smaller than that of the electron or that the nucleus of the element lithium consists of 7 hydrions held together by 4 electrons.

In order to illustrate the modern theory of atomic structure Dr. Moir develops a system of nomenclature, in which the proton is represented by the symbol $\overset{+}{\mathrm{H}}$, and the electron by the symbol θ; and these symbols are used, not only for the protons of the element hydrogen, and for the planetary electrons of various elements, but also as expressing the structure of the nucleus. This analysis of the nucleus introduces an unnecessary element of complexity, which is absent from the lucid explanations given by Lewis; it may even lead to confusion, since the distinction between the permanent nucleus and the movable electrons round it is indicated only by brackets. It is therefore by no means a substantial advance upon earlier methods of formulation when Dr. Moir writes lithium metal as $[\theta(4\mathrm{H}+4\theta\ 3\mathrm{H}+)\theta\theta]$ or the cæsium ion as $27\ \theta(78\mathrm{H}+78\theta\ 55\mathrm{H}+)27\theta$. This nomenclature has, no doubt, become a convenient medium of thought to the author, but it cannot be commended to the average student. In this respect Dr. Moir's pamphlet shows some resemblance to the recent (and not very successful) attempt made by Dr. Gray, of Aberdeen, to "unravel the chemical tangle" (*cf. Chem. and Ind.*, June 29, p. 664). Two examples of the complexity of Dr. Moir's nomenclature may be given, namely, (i) The formulation of the structure of a sodium-fluoride crystal as $[4\theta\,[\mathrm{Na}+^{9}]\,4\theta]\,[4\theta\,[\mathrm{F}+^{7}]\,4\theta]$

with a note to the effect that "The expression $Na+^{9}$ is really $Na+^{11-12}$, the atom having 2 inner electrons to make a kernel out of a nucleus." (ii) A statement that the author's theory accounts for the very low dissociation of water by the fact that the complex $\left[OH_3 \, {}^{19+}_{18\theta}\right] \left[OH \, {}^{17+}_{18\theta}\right]$ yields scarcely any free hydrion.

The author's handling of the structure of the nucleus is by no means lacking in boldness, since he carries his views far beyond the point which has been reached by Rutherford's experiments. Thus he postulates that both carbon and nitrogen have a tetrahedral nucleus, whereas Bohr and other physicists are content to assume some kind of tetrahedral symmetry in the orbits of the planetary electrons. Dr. Moir, however, goes much further than this, and suggests that the silicon nucleus is CHe_4, the zirconium nucleus is CNe_4, titanium is SiNe and niobium NNe_4. On this basis he is prepared to speculate on the possibility that isomorphous mixtures of some of these elements may be the result of transmutation rather than of vicarious replacement.

The features to which attention is directed above certainly redeem Dr. Moir's Presidential Address from any risk of being classed as commonplace; and if only on account of its unconventional character it will be read with keen interest by many who are interested in the problem of atomic structure.

LEHRBUCH DER CHEMISCHEN TECHNOLOGIE.

By Prof. H. OST. *Thirteenth edition* *Pp.* *viii*+815. *Leipzig: Max Janecke*, 1923. *Price* 19*s*.

The thirteenth edition of Ost's *Lehrbuch der Chemischen Technologie*, which appeared in December, 1922, is practically a reprint of the twelfth edition (April, 1922). The rapid succession of new editions indicates a keen demand, at least on the Continent, for a book of this type. There is, so far as the reviewer can recall, no British equivalent to it. The reason for this is probably that for the technical chemist engaged in practice it is not full enough; he will learn practically nothing new in his own particular domain; whilst the student preparing himself for a career in technical chemistry in this country does not usually cover the whole field of chemical technology, as is done in the book under review, but devotes his time mainly to chemical engineering and a detailed study of one or two technical chemical processes. The present edition of Ost's *Lehrbuch* runs to 815 pages, and is divided into short sections dealing with all the important chemical industries. The following summary gives the section headings and an idea of the contents of the sections, when these are not sufficiently indicated by the title. The space devoted to each section is also added:—Introduction, 6 pp.; production of heat (solid, liquid and gaseous fuels), 34 pp.; production of cold, 4 pp.; technology of water, 9 pp.; sulphuric acid (sulphur, carbon disulphide), 26 pp.; salt, 6 pp.; soda, sulphate and hydrochloric acid (caustic soda, sodium), 31 pp.; potassium salts (magnesium salts, bromine, borax, borium compounds), 23 pp.; the chlorine industries, 26 pp.; nitrogen compounds, 31 pp.; artificial manures, 12 pp.; aluminium compounds (sulphate, alums, ultramarine), 8 pp.; explosives (matches, phosphorus), 27 pp.; mortars and cements, 35 pp.; glass, 31 pp.; ceramics, 27 pp.; illuminating gas (other illuminants, hydrogen), 26 pp.; coke and its by-products, 19 pp.; mineral oils (coal tar, low-temperature carbonisation, wood charcoal and destructive distillation of wood), 44 pp.; fats, fatty oils and waxes (milk, butter, margarine, varnishes, resins, rubber, soap, glycerin), 49 pp.; the sugar industry, 40 pp.; starch and starch products (artificial sweetening agents), 16 pp.; cellulose and artificial silk (celluloid and other plastic materials), 14 pp.; fermentation and fermentation industries, 65 pp.; dye manufacture, 40 pp.; dyeing and calico printing (ink), 30 pp.; tanning (glue), 15 pp.; metallurgy, 103 pp.; index, 18 pp.

No one can pretend to write authoritatively on such a variety of subjects, so the volume is largely a compilation from various sources, which are given at the beginning of each section. In the modest space devoted to each industry one cannot expect exhaustive treatment. The book, gives, however, an excellent bird's-eye view of the chief chemical industries. The purely chemical side of the subject is treated comparatively briefly, the main feature being a clear summary of the manufacturing process. In most cases this is excellently done, although the few brief paragraphs in which some of the minor subjects are dismissed convey little more information than the average text-book of general chemistry. The diagrams are good and the information is usually up to date, although naturally it is mainly with German practice that the author is concerned. This, however, should be no disadvantage to British readers. The book can be thoroughly recommended to the student who wishes a short, clear and reliable account of the chief chemical industries and it should also prove useful to the consulting chemist.

Its long-continued success is a sufficient indication that it meets a popular demand. A book dealing with such a variety of subjects and substances requires a good index, and this requirement is satisfactorily met.

J. KNOX

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The market continues to be depressed with little business moving. There is no evidence yet of an early return to normal conditions. Prices, however, are well maintained and there are no important changes to report.

Acetic Acid, 40% tech.	£24 per ton. Still firm, but rather less inquiry.
Acid Hydrochloric	3s. 9d.-5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw.	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Demand steady, export inquiry good.
Arsenic (White)	About £71 per ton.
Bleaching Powder	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Business much below normal.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand.
Copper Sulphate	£27 per ton.
Potash Caustic	£33-£34 per ton. Little moving.
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Potass. Chlorate	3d. per lb. Very dull.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76%	£20-£21 per ton. Steady demand.
Soda Crystals	£5 5s.-£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£26 per ton. Very scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b London, 1-cwt iron drums included.
Sod. Chlorate	2¾d.-3d. per lb. Very dull.
Sod. Nitrate refd. 96%	£13 5s.-£13 10s. per ton ex Liverpool. Steady demand.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	£15-£16 per ton carr. paid. Very quiet. Prices unstable.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25-£29 per ton according to quantity.
Carbon Black	1s. 1½d.-1s. 3d. per lb. Ample supplies now coming forward.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood distillation products.

Acetate of Lime—	
Brown	£11 per ton and upwards. Price very firm and demand keen.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8 5s. to £10 15s. per ton, according to locality of market and type of charcoal.
Iron Liquor	1s. 5d. per gall. 32° Tw. Some sales effected at 1s. 7d.
	1s. 2s. per gall. 24° Tw.
Red Liquor	1s 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 8d. ,, ,, 60% O.P. Firm.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5-£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d.-1s. 2½d. per lb. Market well maintained.
Crude 60's	3s.-3s. 3d. per gall. Market quiet.
Acid Cresylic—97/99	2s.-2s. 5d. per gall. Steady demand.
Pale 95%	1s. 11d.-2s. 4d. per gall.
Dark	1s. 10d.-2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.

Anthracene Oil—	
Strained	8¾d.-11d. per gall. Supply short. Plenty of inquiries.
Unstrained	8¼d.-9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1¼d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.
Pure	2s. 1d.-2s. 2d. per gall.
Toluole—90%	1s. 9d.-2s. per gall. Not many inquiries.
Pure	2s.-2s. 4d. per gall. Not much inquiry.
Xylol	3s. 3d.-3s. 10d. per gall., according to quality.
Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil Heavy Standard Specification	8½d.-9½d. per gall. Market steady. Good demand.
Napbtha—	
Crude	8¾d.-9d. per gall.
Solvent 90/160	1s. 6d.-1s. 7d. per gall. Business quiet.
Solvent 90/190	1s. 5d.-1s. 7½d. per gall. Market moderately active.
Naphthalene Crude—	
Drained Creosote Salts	£7-£8 per ton. Fair demand. Supply short.
Whizzed or hot pressed	£11-£14 per ton. Less active.
Naphthalene—	
Crystals	£18 10s. per ton.
Flaked	£17 per ton.
Pitch, medium soft	132s. 6d.-140s. per ton. Autumn delivery. Numerous inquiries.
Pyridine—90/140	18s. per gall. Demand good.
Heavy	8s.-9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Depression in the textile trade continues, but business in dyestuffs has improved slightly during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 6d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Steady demand.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb.
p-Cresol 32/34° C.	2s. 1d.-2s. 3d. per lb.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 9d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. 6d. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylamine Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Markets are practically stagnant, and with foreign exchanges in violent fluctuation no improvement can be expected at present.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. 1d. per lb. for cwt. lots. Market weaker.
Acid, Benzoic	2s. 6d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8d. per lb., less 5%. Demand improved.
Acid, Gallic	3s. per lb. Down to 2s. 11d. for large quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d. per lb. Still wanted.
Acid, Tannic	3s. 6d. per lb.
Acid, Tartaric	1s. 3¼d.-1s. 3½d. per lb. less 5%. Demand improved on account of warmer weather.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 5d. per lb. now accepted for quantity.
Amidopyrin	12s. 6d. per lb. Now cheaper but demand still very poor.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz.
Barbitone	21s. per lb. No inquiry.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Position unchanged. Prices vary according to quantity and source.
Calcium Lactate	2s. 6d. per lb. for best makes.
Chloral Hydrate	3s. 9d. per lb., duty paid.
Chloroform	2s. 2d. per lb. for cwt. lots. Higher prices are looked for in near future.

Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	£90-£92 per ton. Very firm.
Guiacol Carbonate	8s. 6d. per lb. Neglected.
Hoxamine	3s. 9d. per lb. In fair supply on a quiet market.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots.
Magnesium Carbonate—	
Light Commercial	£37-£38 per ton net, according to quantity.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	70s.-80s. per cwt. Fairly steady market.
Menthol	40s. per lb. spot.
Methyl Salicylate	2s. 4d. per lb. for carboys.
Methyl Sulphonal	15s. per lb.
Morphine	Alkaloid—Cryst. 10s. 11d., Precip. 10s. 8d., Acetate 8s. 6d., Hydrochlor. 8s. 6d. Sulphate 8s. 6d. per oz.
Paraformaldehyde	3s. 9d. per lb. Lifeless.
Paraldehyde	1s. 5d. per lb. Cheaper, with poor demand.
Phenacetin	6s. 6d. per lb.
Phenazone	7s. per lb.
Phenolphthalein	6s. per lb. Lower.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	94s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d. per lb. Good demand. Steady market.
Potass. Permanganate	10½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	5s. 6d. per lb. Cheaper.
Salol	2s. 9d. per lb.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 6d. per lb. Slow of sale.
Sod. Citrate, B.P.C. 1923	2s. 2d. per lb. for cwt. lots. Firmer.
Sod. Hyposulphite—	
Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.-87s. 6d. per cwt. Fairly good demand. Expected to improve with continued warm weather.
Sod. Salicylate	Powder 2s. 7d. per lb., and Crystal at 2s. 9d. per lb. Market lifeless.
Sod. Sulphite, anhydrous	£27 10s.-£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.
Thymol	15s. 6d. per lb. for cwt. lots of natural recryst.

PERFUMERY CHEMICALS

COMPANY NEWS

THE BRITISH CYANIDES CO., LTD.

The Annual Ordinary General Meeting of the British Cyanides Co., Ltd., was held on July 18, when the Directors' Report and Statement of Accounts were submitted. The Report for the year ended April 30 last shows a profit of £17,204, which, with the amount brought forward, makes a total of £17,697. This compares with a total profit last year, including the amount brought in, of £3,342. After the payment of the dividends on the Preference Shares for the year, there remains a sum of £14,847, as compared with £492 for the year 1922, which the Directors recommend should be carried forward.

The Report states that the profits realised were almost entirely earned during the last few months of the period under review. The Tat Bank Works, which, owing to the sudden slump in trade during the previous year, had been closed down, were reopened in February last, and the operations at this factory will be further extended during the coming year with, it is hoped, very satisfactory results.

The balance-sheet shows, apart from loans to subsidiary companies, that stocks of materials, boats, tank-wagons, &c., amount to £52,267; sundry debtors, £30,421 as against creditors, £27,379; cash-in-hand and at bankers, £9,850 as against £4,880 last year; whilst the bankers' overdraft has been reduced from £47,402 to £30,001.

The main idea of the directors has been to secure a source for the supply of raw material, and with this end in view they have entered into a contract for a period for the supply of cyanogen which can be drawn cheaply from the nitrogen of the atmosphere. Large sums of money have been expended on this problem, the solution of which, the directors state, appears to be within their grasp.

PUBLICATIONS RECEIVED

Catalogue of Selected Works on Natural History. *Being recent purchases from the libraries of Prof. G. S. Boulger, F. M. Campbell, Sir F. W. Moore and Sir E. Giles Loder, Bart. Pp.* 70. *London: Wheldon and Wesley, Ltd.*, 1923.

TRADE NOTE

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during June has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee.

The total number of applications received during the month was 512, of which 393 were from merchants and dealers. To these should be added the 21 cases outstanding on June 1. making a total for the month of 533. These were dealt with as follows :—

> Granted—372 (of which 328 were dealt with within seven days of receipt).
>
> Referred to British makers of similar products—96 (of which 78 were dealt with within seven days of receipt).
>
> Referred to Reparation supplies available —41 (all dealt with within two days of receipt).
>
> Outstanding on June 30,—24.

Of the total of 533 applications, 436, or 80 per cent. were dealt with within four days of receipt.

EMPIRE COTTON AND RESEARCH

£5,000 DONATION TO IMPERIAL COLLEGE

The Empire Cotton Growing Corporation has recently been considering the necessity for organised research at the Universities and Colleges of Great Britain and has decided to offer retaining grants to certain Universities, where highly specialised research is already going on. The Cotton Corporation has offered to the Imperial College of Science and Technology, South Kensington, the sum of £1,000 a year for a period of five years from October 1, 1923, the money to be devoted to Plant Physiology and Plant Pathology in the Department of Botany. This generous offer has, we understand, been accepted by the Governing Body and the research work will be undertaken in the new Botany Building, which was recently opened by the Duke of Devonshire and to which the Rubber Growers' Association of the City of London subscribed approximately £30,000 about two years ago. This donation is tangible evidence of the value which tropical agriculturists attach to the important research work which is being undertaken at the Imperial College, especially in connexion with plant physiology and pathology under the direction of Professor J. B. Farmer, F.R.S., and Professor V. H. Blackman, F.R.S. We have no doubt that other groups interested in research work will continue to support undertakings of this character.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JULY 27, 1923 No. 30

EDITORIAL

WE were, a few days ago, wandering idly in a garden, with mind somewhat out of focus, our speculations reduced "to a green thought in a green shade" when our attention was directed to some more vivid patches on the lawn caused by unequal sprinkling of sulphate of ammonia. How small a quantity of this affects the vigour of the grass! In homœopathic doses this is a wonderful stimulant, and it seemed to us that this is typical of many a chemical process, not only in those gardens where the "milder sun does through a fragrant zodiac run," but in the treatment of minerals of many kinds and precious sand from southern climates brought. We have read somewhere *De minimis non curat lex*, but if the law does not bother about trifles no such statement may be made about chemistry. There is hardly such a possibility as pure chemistry. If you take away the traces of water and other more or less accidental appendages the chemical actions diminish in vigour and in interest until hardly anything is left. In our youth two of us could play cricket, one to bat and one to bowl, but how fatiguing and unsatisfactory such a game was. At least a third player is required and half-a-dozen are still better. Is it not the same in chemistry? Variety is wanted; if an electron has only one or two opportunities of attachment it becomes dull and tedious, but give it four or five chances and how busy it gets. The slight impurities found in metallic iron, lead or copper play an extremely important part in deciding the physical and chemical properties of these metals, and how minute a proportion of these impurities, or lubricants, or whatever they are, can be detected; a few pennyweights of silver to the ton of lead may be like an odd mark given away with a pound sterling, but it has a noticeable effect and we can detect in dyestuffs, and scents quantities so small as to require a calculus of infinitesimals to measure them.

A minute quantity of copper sulphate will destroy various animal and vegetable growths; it is said that cattle will not fatten unless in the oil-cake or some other article of diet traces of prussic acid exist—how true this is we do not know—and very faint traces of unwanted substances promote the rusting of iron and many other chemical actions. Now we may read in *Nature* an account of the effect of small traces of formaldehyde in promoting photosynthesis by a living plant, an instance which would have delighted Hahnemann; minute traces promote it, larger quantities poison the plant. The effect of minute traces of moisture on the boiling points of liquids has been freely commented upon during the last few years, though we are not clear whether this does not belong to a different set of ideas. While we were pondering these thoughts in a garden we were advised of a recent paper read before the Royal Dublin Society on hydrogen ion concentration in relation to the distribution of snails. It seems that snails are as intolerant of the hydrogen ion as is Professor Armstrong. These harmless necessary ions are a red rag to the snails. A minute quantity of them to the square centimetre—the mathematical formula given in the paper does not give the limits in a very clear manner—drives them away to languish and perhaps die of undue concentration. If only someone would work out a simple method of obtaining just the right number of hydrogen ions to kill slugs without injuring the plants, what a blessing would be conferred on struggling humanity. The dead slugs would decompose in the first moonlight night and the discoverer of the process would be recommended for the Messel and all other chemical medals. We seem to have heard of a vinegar plant which produces acetic acid, though we have searched Carter's seed catalogue for it in vain, perhaps a few of these planted among the lettuces—who knows?

DEVELOPMENTS IN THE CEMENT INDUSTRY

By REX FURNESS

It is a matter for congratulation that the cement industry in the principal countries of the world has interested itself so keenly in the scientific study of the problems of the manufacture and application of cement. Even if satisfaction is somewhat qualified by the relative lack of attention paid to problems of a fundamental nature, the advances made in the control of the raw materials and in the mixing, in the study of the heat distribution throughout the length of the kiln, in the recovery of heat from the waste gases, the clinker and the kiln shell, etc., in the production of improved refractories for kiln lining, in the investigation of the effect of fineness of division of cement upon quality of concrete, in the manufacture of waterproof and acid-proof cements or concretes, and in scores of other directions, are noteworthy and represent tangible proofs of the value of scientific research in industry.

One development, however, presents so great a possibility of revolutionary change in the cement industry that it calls for special attention. It is not impossible that the near future may witness a change in the composition of cement in general use, and that high aluminous cements may supplant in large measure the ordinary Portland cement of to-day. Such a material is already being manufactured in three French works and is upon the markets under various names—ciment électrique, ciment fondu, aluminous cement, "alca" cement, fused cement, etc.—although supply is in no way equal to demand. That the price is very considerably in excess of that of ordinary cement is no indication of limited applicability, for, even if the cost of manufacture cannot be reduced (and it will appear later that the reverse is very probable), the superior qualities of the new cement will procure for it a ready sale. The development of the Portland cement industry itself, the output of which has increased a hundredfold in two decades, demonstrates clearly that a higher priced cement will displace a cheaper cement—natural cement—when the properties of the former are so markedly superior.

Let us consider briefly the nature and qualities of the new aluminous cements.

Calcium Aluminate Cements

A hydraulic material, consisting mainly of calcium aluminate, is manufactured by fusing together bauxite and lime in an electric furnace, or a water-cooled cupola type of furnace. Although the composition may vary within reasonably wide limits before its properties of slow setting and rapid hardening are impaired too greatly, an average composition may be taken as 40 per cent. alumina, 40 per cent. lime, 10 per cent ferric oxide and 10 per cent. silica.* Thus, whilst we may roughly assume that the amount of lime in all ordinary Portland cements varies between 1·7 and 2·2 times the sum of the amounts of silica, alumina and ferric oxide, the ratio in the new cements is approximately 0·66. Similarly, the silica-alumina ratio in Portland cement is invariably over 2·5, whereas in the calcium aluminate cements now upon the market, this relationship is about 0·25. It is, therefore, to be expected that aluminate cements should differ very considerably in their properties from the ordinary cements, and this is shown in no more striking instances than in their setting and hardening rates and in their compressive and tensile strengths. Cements of the composition above indicated set relatively slowly and harden rapidly. In twenty-four hours the cement mass has attained a strength equal to that of ordinary cement in twenty-eight days, and the ultimate strength is approximately three times that of Portland cement. This is well shown in the table given above, in which a random selection of available figures has been made.†

Cement	Test	One day	Two days	Three days	Seven days	Twenty-eight days	Three months
Ciment fondu—1 : 1 : 3	Compressive	—	—	7500	—	8500	9000

Ciment électrique 1 : 3 mortar	Tensile	468	480	—	488	665	—
Ordinary cement—1 : 3 mortar	ditto	—	—	333	398	—	580

The figures are from French, American and Danish sources, and include some published by Bied and Sprackman, who may be said to have developed calcium aluminate cements, the latter having taken out the original patents. The heat evolved in the setting of the cement mixture is sufficient to allow operations to be conducted in frosty weather, for before the heat is dissipated the mass has hardened to a degree sufficient to resist deformation, etc. It is clear that a rapid hardening, specially strong cement has many advantages. Less reinforcement is required, and beams, floors, etc., can be reduced in dimensions. Work is more rapidly completed—the whole output of the French works was used during the war for the construction of artillery platforms, etc., where rapid completion of work was essential. Pile-driving experiments have shown that operations can be commenced in three days. Economy in material is, of course, possible—for equal strength, relative to Portland cement work—and in cases where forms are used, the economy in form timber is considerable, since a much smaller stock of forms is required. Concrete articles demand less storage time and, in general, the time saved by the use of a rapidly hardening cement reduces overhead charges. A further property of calcium aluminate cements is their resistance to the attack of alkaline soils, sea water and the sulphates of calcium and magnesium. Their applications in submarine work and in alkaline soils require, then, no description.

---

* Reid's formula for cements like "ciment fondu" is 0·4 ($2CaO.SiO_2$) $CaO.Al_2O_3$, but the cement shows satisfactory properties with a composition of 35–45 per cent. Al_2O_3, 35–45 per cent. CaO. 5–12 per cent. of SiO_2 and 5–12 per cent. of Fe_2O_3. Indeed, the setting properties are entirely due to the calcium aluminate. *Cf.* Harms, *Concrete*, Cement Mill Section, June, 1922, p. 119, for a full discussion of the composition of fused cements.

† *Cf.* Sprackman, *Concrete*, March, 1923, p. 113, for a table of the tensile and compressive strengths of various aluminous cements. Further information as to the strength and composition of ciment fondu has recently been given in two papers read—after the writing of this paper—before the Institution of Engineering Inspection, by Davey and Knight.

The above condensed account of the properties of the calcium aluminate cements will probably serve to indicate the undoubted possibilities of these new cements. Their success is already demonstrated, for they have been continuously employed for twelve years, and today the whole of the output of the three French works is booked well ahead, at prices two to three times those ruling for ordinary cement. The general development of aluminate cements will be considerably hastened, however, if the cost of production can be lowered, and if ordinary rotary kilns can be used in their manufacture. It is pertinent, therefore, to discuss the present and possible future methods of manufacture.

Present Methods of Production

A suitable mixture of bauxite and limestone, of the composition noted above, is fused or partially fused in an electric furnace or in a water-cooled blast-furnace type of apparatus, and the resulting mass is cooled and finely ground, in the entire absence of free lime. Many problems, such as the rate of cooling, calcination, fineness of division, etc., are incompletely solved, but it is clear that the manufacturers have sufficient experience to produce a regular quality of slow-setting, rapidly hardening cement. The cost of manufacture is high compared with ordinary cement kiln practice, for in the electric furnace 2000 kw.-hrs. of electricity is required per ton of cement produced. The mass is difficultly fusible on account of its low conductivity—the resistivity of the mass has been placed at two million microhms per sq. cm.—and the electrode consumption is very high, namely, 100—200 kg. per ton of cement made. The attack of the carbon dioxide upon the electrodes at the high temperatures generated must obviously be considerable. Experiments have been conducted in the rotary kiln, but full success has not yet been realised, although Sprackman has stated that the use of the rotary kiln is not impossible.

Possible Future Methods of Production

The manufacture of the high melting calcium aluminate cements, as of a true tricalcium silicate cement, in the rotary kiln is the natural development which is to be expected. Provided certain conditions can be met, there appears no reason why the costs of manufacturing aluminate cement should be higher than those ruling today in Portland cement production. The net cost of aluminate cements should then be no higher, or only slightly higher, than that of ordinary cement to-day. The actual *amount* of heat required to " burn " a ton of aluminate cement is no higher than for Portland cement, and it becomes a matter of *intensity* of heat. The utilisation of all the available methods of heat recovery from kiln gases, clinker and kiln shell, and the high pre-heating of air for the combustion of carbonaceous matter supplied to the kiln will enable a sufficiently high temperature to be attained in the kiln. But the utilisation of temperatures of 1500 and 1600° C. in the kiln necessitates the provision of refractories that are not available to-day. Many heat economy projects for Portland cement kilns have been abandoned by reason of the impossibility of procuring refractories of sufficiently high resistance. None the less, research in this field is very progressive, and new refractories of one sort or another are almost a daily occurrence, and it is not too much to hope that the near future will see the production of a refractory of high resistance, strong and free from cracking troubles, at an economical figure. A high grade silica brick is already being used in cement kilns in order to allow greater heat retention in the waste gases—passing to waste heat boilers—without risking damage to the kiln shell.

Supply and Cost of Raw Materials

If, then, it becomes possible to manufacture a cement demanding a very high sintering or melting heat in the rotary kiln, at an economical rate, the final determining factor in cost reduction will be the supply of suitable raw materials. Now, although bauxite is by no means so widely distributed in nature as are the clays and marls employed in ordinary cement manufacture, there are deposits which will furnish a suitable raw material for aluminate cement manufacture at a technically economic price. In the first place, a " standard " bauxite is not essential, and the high-grade bauxites used in the production of aluminium or aluminium salts are not essential for making aluminate cement. Siliceous and ferrous impurities, even in relatively large amounts, do not render a bauxite unsuitable for the production of a rapidly hardening, high-strength cement. The known deposits in France, America, Canada, Germany, India, Australia, County Antrim, and other localities vary widely in composition, and there is little doubt that other sources are in existence. Even at present a high-grade French bauxite can be imported at approximately £2 per ton, a figure considerably in excess of that charged in the Portland cement industry for the necessary clay or marl, but one which would add relatively little to the final cost of a calcium aluminate cement.

It is unwise to discuss a cost figure in the abstract, but it is apparent that, broadly speaking, the raw materials—limestone and some form of bauxite—for calcium aluminate cement manufacture—should become available at prices allowing of the manufacture of such a cement at a figure not greatly in excess of that ruling now for ordinary Portland cement. The other factor—again admittedly indeterminate—is the manufacturing cost, dependent not upon the *amount* of heat required to burn the cement, but upon its *intensity*. The cheapest electrical energy is still costly in this application, and it will remain for the manufacturers of refractories to produce a high-grade kiln lining which will allow a high temperature to be attained within the kiln without rapid disintegration of the lining or damage to the kiln shell. Granted this development, the creation of the required temperature is relatively simple and cheap, and the way becomes open for the employment of the rotary kiln in the manufacture of "high temperature" cements.

Recovery of Waste Heat

Quite apart from, but pertinent to the manufacture of a highly aluminous cement, is the question of the recovery of "waste" heat. Of the heat generated by the hundred or so pounds of fuel used in the production of a barrel of cement—roughly three times the theoretical amount—a large proportion is ordinarily lost in the gases passing to the stack, whilst smaller amounts pass away by radiation from the kiln shell and from the discharged hot clinker. Within recent years a great advance has been made in the recovery and utilisation of this heat by means of waste heat boilers (in which steam is generated by the heat of the gases), by clinker coolers and shell linings which furnish preheated air for combustion of fuel in the kiln.

Waste-Heat Boilers

Since 1915, when the first attempt to recover heat from cement kiln gases was made at Louisville U.S.A., the installation of the so-called waste-heat boilers has progressed, so that in 1918 there were eight boilers in operation, whilst to-day there are over two dozen. The reports of their successful working have been vouched for by the U.S. Portland Cement Association, and there is little doubt that they will be rapidly adopted by most producers. It is calculated that the U.S. cement industry will be recovering the equivalent of two million tons of coal annually within five years by the use of waste heat boilers. A simple calculation will show that the heat carried by the escaping gases is more than is required to generate all the electrical power needed in a cement plant, including power for kiln, grinders, fans, conveyers, etc. In practice, this has been achieved more often than not, and in certain cases where this has not been realised, it is to be noted that abnormally low fuel consumption figures were being already registered. In the Louisville plant already mentioned, the average yearly fuel consumption in the boiler house fell from 91·7 to 40·2 lb. per barrel of cement produced in the kiln. Similarly, a German plant is generating 745 kg. of steam per ton of cement produced, a calculated theoretical figure of 800 kg. being almost reached, and all the power necessary for cement production is supplied indirectly from the kiln gases. The proved success of the waste heat boiler in general industry should help to induce all cement manufacturers to consider the installation of such aids to economical working. Thus, the Babcock Wilcox Co., in the United States, has erected boilers representing a total of over 150,000 rated boiler horse-power, of which 10 per cent. operate in conjunction with cement kilns. The largest application is in heat recovery from the open-hearth furnace, whilst heat is recovered from the waste gases from metal furnaces, gas benches, beehive coking-plants, glass tanks, stills, etc.

It is unnecessary to describe in detail the construction of the proved types of waste-heat boilers, and it will suffice to say that practically all the difficulties due to infiltration of air, resistance to gas flow, cleaning of boiler tubes, etc., have been successfully met. Dust is mechanically removed several times a day, and draught is well and uniformly maintained. Economy is effected by using the exhaust steam from the fan turbine to preheat the water passing to the boiler. The cost of an efficient waste-heat recovery apparatus is by no means inordinately high, and the depreciation and maintenance charges are very low. Indeed, it has been officially stated that several of the waste-heat boilers installed to recover heat from open-hearth furnace gases paid for themselves in two years. The heat recovery from cement kiln gases is no less profitable, and the comparatively high temperature of the gases from the "dry process" of cement manufacture renders highly efficient recovery relatively simple. Moreover, it is by no means impossible to recover heat at a profit from gases from "wet process" kilns, although it is admittedly easier to do so from the hotter gases from "dry process " kilns. In other words, the heat in gases at about 900° C. is more efficiently utilised than the same amount of heat in double the quantity of gases at, say, 500° C. Still, waste-heat recovery boilers are in successful and profitable operation with the entering hot gases at a temperature as low as 450° C.

Recovery of Radiated Heat

A rotary cement kiln, 200 ft. in length and 8 ft. in diameter, radiates from its surface in a year's operation an amount of heat equal to approximately 1250 tons of fuel. The recovery or retention of this wasted heat, however, is not simple. Ordinary insulation, for instance, by means of a silica brick lining between the usual firebrick lining and the outer shell may lead to a rapid disintegration of the firebrick lining, by reason of the greater heat in the kiln. The saving in fuel is lost many times over by the consequent cost of lining renewal. It has been shown possible, none the less, to insulate a portion of the kiln, and several American kilns are fitted with silica bricks between the shell and firebrick lining, for a portion of the length of the kiln, where heat intensity is not likely to be increased to a destructive level. More heat is retained in the apparatus as a whole, therefore, and provided waste heat is recovered from the gases, now hotter than ordinarily, a balance of profit can be obtained. Of a different character is the proposal to surround the kiln with an insulated housing through which cold air is drawn at a high velocity. The air becomes heated and is passed to the kiln, in which, therefore, a higher efficiency of fuel consumption is attained. Inspection windows are provided, and the interior of the housing being dark, "hot spots" in the kiln are more easily discovered.

In all such operations, however, it must be carefully considered whether the value of the heat recovered is not more than balanced by the cost of recovering it, namely, in power for air circulation, supervision, capital cost, depreciation, etc., and this is especially to be noticed when a clinker cooler is already supplying preheated air to the kiln. Nevertheless, by the installation of heat recovery devices, it is possible to increase the efficiency of fuel utilisation in cement burning to a figure easily double that now obtaining in general practice, say, about 33 per cent., and figures of coal consumption near the theoretical amount of about 30 lb. per barrel of cement burned are foreshadowed.

The question assumes another aspect, too, when the future is considered. A carborundum-like refractory, which will withstand higher temperatures than are in common use will be produced at a price allowing its use in kilns. It will then be possible to make high-melting cements in the rotary kiln and heat recovery in full measure will be necessary in order to attain the required temperature and to lower production costs of cement made from relatively dear raw materials (compared with ordinary Portland cement).

In conclusion, it must be stated that these developments, important as they are, do not by any means cover the field of progress in which the cement industry is expanding. Reference can only be made to the recovery of potash from cement kiln dust—a very profitable matter during times of potash shortage, the reduction of the amount of water in the " wet process " slurry by the addition of sodium carbonate in small amount, the control of draught, stack gases and temperature in the kiln, the investigations of the influence of the modulus of fineness or apparent specific gravity of cement, in addition to that of fine grinding, *per se*, upon the general properties of Portland cement, the investigations on integral waterproofing agents, inquiries into the optimum amounts of water, aggregate, etc., and into the best size of aggregate for concrete making, experiments upon the influence of salts, etc., upon the setting, hardening, disintegration, etc., of concrete, and to many other problems in the making, use, storage, handling and transport of cement. In connexion with researches of a nature more basic to the whole industry, we can only keep the parable of the grain of mustard seed in mind, and hope that a wise judgment will be in evidence.

RECENT PROGRESS IN THE TREATMENT OF TUBERCULOSIS

Serum and vaccine therapy have hitherto been disappointing in their results when applied to the cure or amelioration of tuberculosis and certain other diseases due to pathogenic organisms.

The trend of recent work has therefore been toward the development of antiseptics, with a powerful bactericidal action on the bacillus of tuberculosis, such as are described in the Annual Reports on the Progress of Applied Chemistry, Vol. VII.

Professor Dreyer of Oxford has, however, in the current number of the *Journal of Experimental Pathology*, reviewed the whole field of experience of vaccine and serum therapy and points out that, broadly speaking, success is obtained with bacteria which are non-acid-fast and Gram-negative, and failure with acid-fast and Gram-positive bacteria. This property of being acid-fast and Gram-positive is associated with the presence in the bacteria of fatty or lipoidal substances which prevent the particular dye, which has been used for staining, from being washed out either by 20 per cent. solutions of sulphuric or nitric acids (acid-fast) or by alcohol (Gram-positive).

In other words the failure of vaccines containing the dead bodies of acid-fast bacteria to produce an immunity response (development of antibodies) in an animal invaded by such bacteria, is probably due to the protection of the specific bacterial proteins introduced in the vaccine, by the lipoidal constituents.

Success might, therefore, be expected if vaccines could be prepared from acid-fast and Gram-positive bacteria, in which the specific bacterial proteins were liberated from their lipoidal constituents. Professor Dreyer has succeeded in accomplishing this by treatment of the acid-fast bacteria by strong formaldehyde solution followed by exhaustive extraction with acetone at 65° C. Such treatment applied to non-acid-fast and Gram-negative organisms, such as *B. typhosus*, did not destroy the well-known antigenic power (*i.e.*, the power of causing the production of antibodies when injected). When applied to the acid-fast and Gram-positive organism *B. tuberculosis* and others, it was found that the defatted bacteria were no longer acid-fast or Gram-positive and were digestible by trypsin. Most important of all they could act as antigens in the animal body, giving rise to an immunity response recognisable by various tests familiar to the bacteriologist under the terms bacteriolysins, complement-fixing substances, agglutinins and precipitins.

Experiments on rabbits and guinea-pigs suffering from tuberculosis with the defatted *B. tuberculosis* antigen brought about a definite improvement, with healing of the tuberculous lesions and restoration to more normal body weight. This justified the application of the antigen to human subjects. The results obtained at the London Hospital by Drs. Fildes and Western in the treatment of 60 cases were embodied in the statement: "Improvement has taken place in nearly all cases, and is in our opinion of an order which exceeds obviously that obtainable by any other form of treatment which is applicable to these conditions."

Time and concentrated experimental effort alone will reveal the full value of this antigen. The principles are widely applicable and Professor Dreyer records the preparation of similar antigens from *Staphylococci*, *Streptococci*, *B. diphtheriæ* and *B. anthracis*. One obvious development is the possible production of a tuberculosis antitoxin by injection of horses with the new antigen in a manner somewhat similar to the production of diphtheria antitoxin, the first great contribution of bacteriology to practical therapeutics.

Dr. O. L. Brady has been appointed Reader in Inorganic Chemistry in the University of London, University College, and the title of Emeritus Professor has been conferred on Dr. W. D. Halliburton, M.D., F.R.S., on his retirement from the Chair of Physiology at King's College, which he has held since 1890.

THE ALEMBIC CLUB

On the initiative of the late Prof. John Gibson, who was at the time chief assistant to Prof. Crum Brown in the Chemistry Department of the University of Edinburgh, the five assistants in that Department resolved, on October 29, 1889, to form a Club to which the above name was afterwards given. The objects of the Club, as detailed in the minutes of the meeting on November 19, 1889, at which a set of rules was adopted, were stated to be :—

1. To secure the better recognition of the University of Edinburgh as a School of Chemistry and a Centre of Chemical Research.
2. To encourage the study of the History and Literature of Chemistry, and to enable the members to keep abreast of the progress of the Science.
3. To promote, by individual and collective effort the professional advancement of the members.

The rules of the Club did not demand that members should possess only a single Christian name, but chance ordained that the five original members should be similarly gifted in this respect. In the order of their seniority in the University Department of Chemistry, the five were :—John Gibson, Leonard Dobbin, Hugh Marshall, James Walker, and Alexander Smith. By the unanimous vote of the members, the total membership was, on February 17, 1891, increased to six by the election of Ralph Stockman, in whose case the limitation to a single Christian name was, oddly enough, maintained.

By its rules the Club was to consist of Ordinary and of Corresponding Members—the former limited to seven, to be resident in or near Edinburgh and to become, automatically, Corresponding Members on ceasing to be so resident. The total membership was not to exceed thirteen. In actual fact it never exceeded the six already mentioned.

In an unostentatious manner the members at once set about carrying out the objects for which the Club was founded. For ten or twelve years, during session time, meetings were held once a month at the various ordinary members' houses, in rotation, at which summaries were given of important papers appearing in the current periodicals which each member had undertaken to watch and report upon ; or at which, if not present in person, communications were received from the (at first) sole Corresponding Member, Alexander Smith, who occupied successive teaching positions in the United States.

When teaching duties permitted, various lines of original investigation were taken up by members and papers from the University Laboratories were published from time to time in the Royal Society of Edinburgh, in the Chemical Society, and elsewhere.

In 1893 the Club began the publication of reprints and translations of papers of historical importance in chemistry, the first of these being, appropriately, Black's paper on *Magnesia Alba*, of which the substance had been embodied in a thesis presented by Black, in 1754, to the University of Edinburgh for the degree of M.D. Other important papers, extracts from books, and translations followed for a number of years. In this connexion a specially noteworthy point is the great interest which was taken in the English edition of Mayow's *Tractatus Quinque* by Prof. Crum Brown, who himself translated several of the shorter tracts and most laboriously revised a MS. translation of the longest one which had been prepared some time previously by a non-chemical student of Latin and required close comparison with the original and many alterations. Without this interest and the labour ungrudgingly expended in connexion with the translation, it is practically certain that an English Mayow could not have been included amongst the Club's publications. The primary object of the publication of these papers was to facilitate the work of students who desired to familiarise themselves with some of the classics of chemical discovery but for whom there was no easy access to the originals or no English version. Incidentally it was hoped that their publication would aid in encouraging students to cultivate the habit of consulting the original literature of chemistry. The gratifying measure of acceptance which the Club's " Reprints " met with at the hands of the authors of text-books as well as of teachers and students, both in Britain and in America, showed that these were appreciated in chemical circles generally and that they served to fill a place in University training in chemistry.

The activities of the Club have not been confined solely to the furtherance of the objects specified in its constitution, but have extended to certain social events. Once a year, during its earlier career, a summer afternoon run was made to some place of interest in the Edinburgh district, where a simple and quiet dinner was enjoyed ; whilst a more elaborate, but no less pleasant function, marked the promotion of a member to a Chair—occasions of which many happy memories remain.

In the course of time members got separated through obtaining appointments at various teaching centres, and the monthly meetings were no longer held ; but it was not till 1913 that the Club sustained its first loss of a member through the death of Hugh Marshall, who then occupied the Chair of Chemistry in University College, Dundee. Since that date, two other members have died—John Gibson, Professor of Chemistry in the Heriot-Watt College, Edinburgh, in 1914, and Alexander Smith, Professor of Chemistry in Columbia University, New York, in 1922 ; so that of the total membership only one-half now remains.

PERSONALIA

The Court of the Salters' Company has appointed Prof. A. Smithells to the Directorship of the Salters' Institute of Industrial Chemistry.

The following elections to Fellowships and renewals of Fellowships for the year 1923-24 are announced by the Trustees of the Ramsey Memorial Fellowship :—*British Fellowships* of £300 each to Dr. S. Coffey, A. F. Titley, B.Sc., and Dr. R. W. Lunt, M.Sc. (Renewals). *Glasgow Fellowships* of £300 to T. S. Stevens, B.Sc., and J. A. Muir. *Norwegian Fellowship* of 5400 kroner to Mr. G. Weidsmann (to work at Cambridge under Professor Gowland Hopkins). *French Scholarship* of £100, plus 14,000 francs, to Dr. H. Weiss (to work under Professor Sir W. Bragg at the Royal Institution). *Netherlands Fellowship* of £300 to Dr. J. Kalff, and a *Danish Fellowship* of £300 to Mr. K. Hjandahl (to work at Liverpool University). Appointments to the Canadian, Greek, Italian and Swedish Fellowships are to be announced shortly.

The following announcements of elections to Beit Memorial Fellowships for Medical Research are quoted from *Nature* :—Fourth-year Fellowship, Dr. K. H. Coward (Metabolism of Young Animals with special reference to Deficiency Diseases). Junior Fellowships : Dr. J. M. H. Campbell (Oxygen Consumption and Metabolism under Diseased Conditions) ; Mr. C. G. Lambie (Influence of Insulin upon Fat and Protein Metabolism) ; Mr. W. K. Slater (An Investigation of Cell-Mechanism) ; Mr. C. P. Stewart (Investigation of Thyroxin) ; Mr. H. J. Channon (The Study of Fundamental Dietary Factors in Nutrition) ; Mr. W. Smith and Mr. L. B. Winter (Investigation of the Metabolism of Carbohydrates); Mr. C. S. Hicks (The Biochemistry of Goitre).

* * *

We announce with regret the death of Mr. F. I. Scard, a well known sugar chemist. Mr. Scard was responsible for the adaption of phosphoric acid to the manufacture of Demerara sugar and the use of ammonium sulphate in the distilleries in British Guiana.

The death of Prof. E. Beckmann, on July 12, a few days after he had celebrated his 70th birthday, marks the passing of an outstanding figure among German chemists. A prolific worker, Beckmann will perhaps be remembered chiefly for his apparatus for the determination of molecular weights by the freezing-point method, employing his differential thermometer, for his sodium press and for the reaction bearing his name that has proved so valuable an aid to research in organic chemistry.

The death is reported of Prof. L. Vignon, honorary director of the School of Industrial Chemistry at Lyons, and a member of the Council of the Société de Chimie Industrielle. Prof. Vignon had carried out important investigations on cellulose esters and on silk.

ACADÉMIE DES SCIENCES

At the meeting held on July 9, Professor Vincent presented a note by Dr. Bazin, which was of great interest to chemotherapists, as the author has found that cancerous growths of animals can be transmitted to human beings and vice versa.

On July 16, Professor Urbain read two papers, one on "Nickel Complexes," and the other on "The Ionisation produced by Hydration of Sulphate of Quinine." Professor Urbain also communicated a paper by Monsieur P. Auge on β-rays, and Monsieur Haller presented an account of the meetings held at Strasburg to commemorate the two famous chemists, Charles Gerhardt and Adolphe Wurtz.

NEWS AND NOTES

UNITED STATES

The Universal Gas-mask

In Technical Paper 300, published by the United States Bureau of Mines, an account is given of a new mask of general utility for the chemical, metallurgical and related industries. Special masks have been developed for use against specific gases, but this mask is the first produced which may be used in carbon monoxide, ammonia and in many other poisonous atmospheres. The mask weighs about 8½ lb. Inspired air enters the canister at the bottom through a check valve and a wire dome supports the absorbents which, in 8 to 20 mesh sizes, are arranged as follows in order of position from the bottom upwards. *Dry, activated charcoal* (700 c.c.) to absorb organic vapours, followed by a filter of cotton wool between two light wire screens to remove suspensoids. *Caustic soda fused on granular pumice stone* (300 c.c.), to absorb acid gases and moisture, followed by another cotton wool filter, and a layer of *fused calcium chloride* (400 c.c.) to remove any further moisture. Above the calcium chloride is a wire screen followed by 500 c.c. of *hopcalite* (mixture of oxides of manganese, copper, and sometimes silver and cobalt) which catalyses the oxidation of carbon monoxide to dioxide. After another wire screen comes 700 c.c. of *silica gel* to remove ammonia and other organic vapours, and to prevent moisture reaching the hopcalite from above. A cotton wool filter holds the materials in place through pressure by a spring. Tests conducted on a large variety of gases show that the life of a mask approximates to 14 hours, but a period of 6 hours has been chosen as an arbitrary life, because of the inability of the wearer to detect the penetration of carbon monoxide. The mask, however, does not protect the wearer against methane, and cannot be used in atmospheres deficient in oxygen or those containing very high concentrations of toxic gases. In general the mask should not be used in toxic gases having a concentration of more than 1 or 2 per cent.

AUSTRALIA

Superphosphate Manufacture in Tasmania

After experiments extending for some years the Electrolytic Zinc Co. of Tasmania is about to undertake the manufacture of superphosphates in that State. Zinc concentrates carry between 25 to 35 per cent. of sulphur, which has to be eliminated by roasting before the zinc can be utilised. Until recently 40,000 to 50,000 tons of sulphur were used annually in Australia for the manufacture of sulphuric acid. The company has therefore decided to construct a sulphur works at Risdon to produce 45,000 t. per annum and to duplicate the works which has been operated successfully for some years in the north-west for the roasting of zinc concentrates for the production of sulphuric acid to be utilised in producing superphosphates and other fertilisers. The programme involves the treatment of 20,000 to 30,000 t. of zinc concentrates annually and the production of a similar quantity of sulphuric acid. It is estimated that the large plant required will cost between £200,000 to £250,000, and it is expected that within a short period over 30,000 t. per annum of superphosphates will be produced in Australia from Australian raw material.—(*Ind. Aust., May* 17, 1923.)

CANADA

New Felspar Deposit

A deposit of felspar containing a high percentage of potash has been discovered in Ontario five miles from Perth. The deposit consists of a dyke 1000 ft. long, 300 ft. wide, and 40 to 50 ft. high. It contains many thousands of tons of marketable felspar. Samples tested by a large manufacturer of insulators were reported to be satisfactory.—(*Chem. and Met. Eng., July* 9, 1923.)

GENERAL

Research on Industrial Fatigue

The third annual report of the Industrial Fatigue Research Board has recently been published by H.M. Stationery Office (price 2s.). In Part I of the Report, a general account is given of the organisation of the Board and of the investigations and researches conducted under its auspices, researches including such important subjects as productive efficiency in cotton-weaving; the construction of and ventilation of drying stoves in potters' shops; the effect of atmospheric conditions in the laundry industry, and an investigation relating to the glass industry. Part 2 of the report contains a number of personal contributions from investigators, which will be found of great interest. The report concludes with a list of 22 reports and other publications already issued under the auspices of the Medical Research Council.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for July* 19)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
British India	Steel (tender)	*
Canada	Hospital supplies	11603/E.D./C.C./2
Cuba	Paper	8355/F.L./M.C./2
Netherlands	Technical and surgical rubber goods	69
New Zealand	Steel (tender)	11690/E.D./E.C./2
Norway	Asbestos, linseed oil	70
,,	Agar-agar	73
Panama	Paper	91
Siam	Steel (tender)	10957/F.E./E.C./2
Switzerland	Chamois leather	19073/F.W./M.C./2
United States	Coal - tar products, chemicals	83
,,	Shellac, varnish gums	86
,,	Linseed and rapeseed oil	20066/F.W./C.C./2

TARIFF CUSTOMS EXCISE

Egypt.—Revised valuations have been made for use in assessing the duties leviable on non-ferrous metals.

Latvia.—The export duty on iron and steel scrap has been increased.

New Zealand.—Notice is given of the customs treatment of German, Austrian and Hungarian goods, including paper, iron tubes, rubber tyres, glass, perfumery and metals.

South Africa.—Additions have been made to the list of goods which are duty-free when grown, produced or manufactured in the United Kingdom, but which are otherwise dutiable at 3 per cent. *ad valorem*. Among these are oxalic acid, ammonium oxalate, leather, lead pigments, potassium and sodium metabisulphite, and other chemicals.

United Kingdom-Czechoslovakia.—A Treaty of Commerce between the United Kingdom and Czechoslovakia which was signed in London on July 14, is given in the issue of July 19. The treaty will come into force provisionally on September 1, pending the exchange of ratifications. It includes eleven articles and a list of goods is given, quantities of which will be admitted annually into Czechoslovakia. The list includes artificial silk, essential oils, rubber and leather goods, soap, perfumery, asbestos, coal-tar dyes, chemicals, paint and varnish, fertilisers, metal wares, paper, and lubricating oils.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Patents

Lieut.-Colonel Buckley, replying to Colonel Newman, said that the Government was in communication with the Irish Free State as to the course to be adopted by the latter as regards the granting of patents in future. In the meantime, as far as he was aware, the position of licensees under patents granted with validity throughout the United Kingdom has not been affected.—(July 5.)

Importation of Rubber Tyres

The Prime Minister, replying to various questions, said that he was aware of the enormous increase in the importation of motor tyres into this country and of the effect that it would have on the important British rubber industry. The questions would receive careful consideration by the Government.—(July 18, 19.)

Reparation Levy on Scientific Publications

In answer to Mr. Gray, Sir W. Joynson-Hicks said that any publication in the German language which was a periodical publication of a German learned society or other scientific or philosophical periodical publication was exempt from the provisions of the German Reparation (Recovery) Act, 1921.—(July 19.)

Sugar

Sir P. Lloyd-Greame, answering Mr. Barnes (who had asked whether he was aware that quantities of refined sugar imported into this country from the United States had had to be reshipped owing to the lack of market here), said that the quantity of refined sugar imported into England from the United States, and which had been reconsigned to that country during the first six months of the current year, was only about 100 tons.—(July 17.)

Australian Zinc Concentrates

Answering Mr. Collison, Sir P. Lloyd-Greame said he was not aware of any Australian lead contract. With regard to the Government contract for the purchase of zinc concentrates, pages 209 to 213 of House of Commons Paper, No. 92 of 1923, contained the information asked for. It was impossible to say what would be the results of the contract, which must depend upon the price of spelter.—(July 17.)

COMPANY NEWS

MOND NICKEL CO., LTD.

At the ninth annual general meeting, held on July 19 in London, Sir A. Mond, who presided, said that the demand for nickel, which had been very small, improved considerably during the last year. This improvement was being maintained, and both turnover and deliveries were satisfactory. Production had increased, but prices, owing to unrestrained competition, had been lower than at almost any other period of the industry and thus counteracted to some extent the benefits due to the larger sale and production. The extent of the recovery was shown by the fact that the credit balance in 1923 was £307,000, compared with £299,000 in 1922 and £222,000 in 1921. Before the war about half of the company's output of nickel was used for making armament steel, the remainder being used in manufacturing non-ferrous alloys and pure nickel articles. During 1922, only 12½ per cent. of the output went to steel makers, the remainder being consumed for the other purposes named. The large development of the nickel-copper, nickel-chrome and similar non-ferrous alloys and the greater use of pure nickel goods had saved the situation. Nickel was being increasingly used for coinage, and Messrs. Sankey and Co. had taken up the manufacture of nickel cooking-utensils from nickel sheets rolled by the company's subsidiary, Henry Wiggin and Co., Ltd., Birmingham. Whereas solid nickelware cost more originally, it lasted for ever, required no repairs and had great hygienic advantages. Further outlets were being found in the motor-car industry and in the resistance wires used for electric heaters. Messrs. Henry Wiggin and Co. were putting out a new nickel alloy called "Corronil," which was highly resistant to corrosion. This new alloy was being manufactured in the United States by a company at Clarefield, Pennsylvania, in which the company had a large interest. The future in the United States was very promising and a distinct development was the use by the Westinghouse Company of malleable bar nickel for turbine blades. America was the largest market for nickel in the world to-day, and the company had accordingly increased its investment in the American Nickel Corporation. The position and future of the mines and other plant were satisfactory and all operations were carried out smoothly and efficiently both in Canada and at the refining works in South Wales.

It was decided that a dividend be declared of 7 per cent. for the year ended April 30 (including the interim dividend paid on March 23, 1923) to the holders of the 500,000 cumulative preference shares and the 2,000,000 non-cumulative preference shares of £1 each, numbered 1 to 2,500,000.

REVIEWS

Textile Chemistry: An Introduction to the Chemistry of the Cotton Industry. *By* F. J. Cooper. *Pp. ix*+235. *London: Methuen and Co., Ltd.*, 1923. *Price* 10*s.* 6*d.*

The book is specially designed for students preparing for examinations, and is the result of long experience in training such students. It contains chapters on chemistry, textile fibres, machinery, sizing, dyeing, bleaching, mercerising, etc., and the only justification for treating such a variety of subjects in one volume is that the book is designed to prepare students to cover the syllabuses of examination boards. But beyond this use it can be commended to all students engaged in the cotton industry particularly if it is a means of urging those students to take up the study of chemistry more deeply.

The part dealing with pure chemistry contains a large number of diagrams which are exceedingly well done, and instruction is given in the art of making sketches of apparatus. This training should be very useful to students engaged in industry.

The chapters on bleaching and mercerising are poor and should be rewritten for subsequent editions. After cotton cloth is treated with bleaching powder solution it is well washed and then immersed in acid. Acid is not used "to liberate chlorine," for the good bleacher avoids this liberation at all times. Then Mercer did not discover the lustring of cotton by caustic soda. He noticed the shrinkage of the cotton, but Lowe discovered the lustring, and on the latter discovery present day mercerising is based. The work of Gladstone on the action of caustic soda on cotton is not of sufficient interest nowadays to justify its inclusion in an elementary text-book.

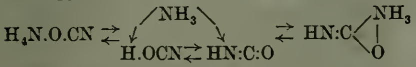
S. H. Higgins

The Chemistry of Urea. *The theory of its constitution, and of the origin and mode of its formation in living organisms. By* Emil A. Werner, M.A., Sc.D., F.I.C. *Monographs on Biochemistry. Pp. xii*+212. *London: Longmans Green and Co.*, 1923. *Price* 14*s. net.*

With this book the series of Monographs on Biochemistry, which have now been edited by Professors Plimmer and Hopkins for well over a decade, reaches the very acme of specialisation. More than half of the book is devoted to disproving the generally accepted constitution of one of the simplest of carbon compounds, one of the few compounds of which every medical student can write the structural formula, or, as it now appears, wrongly imagines he can. The book also constitutes a severe indictment of successive editors of the Chemical Society's *Journal*, who have prevented chemists, at least organic chemists, from writing "urea," and insisted on the use of the term "carbamide." For lo ! urea is not at all the amide it was supposed to be, but a substance with a cyclic formula and a quinquevalent nitrogen atom :

Another unsuspected consequence of this is that the new Beilstein is wrong in dealing with urea in Vol. III. ; it should have been deferred to a much later volume !

The author begins with the discovery of urea just 150 years ago, and has tried to include every reference to theoretical and experimental work which has contributed to the chemistry of urea proper. Wöhler's synthesis, of course, figures largely, and the author is particularly concerned with the mechanism of the change. He suggested in 1913 the following scheme :



The various reactions and other syntheses of the compound are then considered in relation to this new formula. The obvious objection that only one monomethyl urea is known is countered by the suggestion that the other form is so unstable that it has not yet been isolated. Its isolation would indeed be a powerful argument for Prof. Werner's formula ; one interesting result of this formula is the light it throws on the action of urease. Some results by W. R. Fearon are quoted (since published in the *Biochemical Journal*), which include the observation that cyanic acid and biuret are formed, and seem to explain why the urease action is not reversible.

The monographs on biochemistry are presumably intended for biochemists, and after being taken through rather more organic chemistry than they are used to, including electronic formulæ with positive and negative radicles, they will turn, perhaps with some feeling of relief, to a chapter on the occurrence of urea in nature and the formation of urea in animal metabolism. In it they will find much food for thought ; but in the next chapter they will have to leave living organisms again and consider Langmuir's application of the octet theory to ammonium salts, and will find nothing further of specifically biochemical interest until they reach an appendix dealing with methods for the detection and estimation of urea, where the urease and xanthhydrol methods together occupy slightly more than two pages. Industrial chemists will find a few pages on the large-scale synthesis of urea as a fertiliser, and will have to take account of the author's theories in further work on the subject. Teachers will welcome the description of some fifteen lecture experiments, mostly in support of the author's views.

A bibliography is one of the features of the biochemical monographs. In the book under review it is of moderate dimensions and arranged chronologically. The price of the book is 14s. net. That of Dakin's *Oxidations and Reductions in the Animal Body*, of nearly the same size, recently reviewed in these columns, is 6s. net. The one was printed in Britain, the other in Germany. An impecunious student will be able to buy much more biochemical information in the cheaper book. However, the editors and publishers of the series have shown that they know their business, and doubtless *The Chemistry of Urea* will sell sufficiently in spite of its price.

In his preface the author says that he has aimed at writing for the laboratory as well as for the study ; it is, however, to a place in the latter that his book can best lay claim. The practical information seems to be subsidiary ; apart from the lecture experiments, the matter is readily accessible elsewhere. In its theoretical part the book is less of a compilation, and more concerned with the author's own work and views than most other monographs. Herein lies its chief value : as a challenge to current ideas, as a stimulus to further work. As such the reviewer welcomes it and as such he wishes it well.

GEORGE BARGER

ÜBER NATURPRODUKTE. *Chemische Abhandlungen zur Kenntniss und Verwertung Verschiedener Naturprodukte. Volume to commemorate the 70th birthday of* PROF. MAX HÖNIG. *Pp.* 180. *Dresden ; Th. Steinkopff*, 1923. *Price* $1·10.

This volume contains 24 short dissertations by well-known chemists, in most cases a summary of results of recent research work upon particular subjects, such as "Cellulose," C. F. Cross ; "Lignin, Vakuumdestillation," F. Fischer, H. Tröpsch and W. Krönig ; "Synthetische Versuche (Constitution)," P. Klason ; "Salzsäurelignin," E. Hägglund ; "Pentosangehalt," K. Kürschner ; "Huminsäure," W. Fuchs and P. Stamberger ; "Inulin," H. Pringsheim ; "Stärke" (quantitative Bestimmung), F. Tempus.

In addition to these, there are papers on technical subjects such as industrial water supply, sugar refining, sulphite by-products (lignon sulphonates) in the tanning industry, fertilisers and field experiments, and lastly a paper by C. Frenzel and E. Klarmann, "Die Röntgenstrahlen in ihre Anwendung in Chemie und Technik."

The volume is worthy of note for these special contributions, but particularly as a tribute to Max Hönig and his long life of devotion to industrial chemistry, marked by many successful applications of the results of systematic research to technical progress. The volume is prefaced with a list of more than 50 of Hönig's original papers ; these, with a photograph of the Professor, complete a worthy memento of his life's work.

C. F. CROSS

MANUFACTURE OF CHROME LEATHER. *By* M. C. LAMB, F.C.S. *Pp.* 420. *London: The Anglo-American Technical Co., Ltd,* 1923. *Price* 26*s*.

When Professor Procter published his first edition of *Principles of Leather Manufacture* in 1903, it was his intention to publish another work on methods of leather manufacture. He did not find an opportunity of so doing, but one of his students, H. G. Bennett, published a similar work which included most of the vegetable-tanning processes. Very little information was given in either of the above-mentioned works on chrome tanning, which has developed very considerably since the commencement of the present century.

There was a great scarcity of technical literature prior to 1914 on the subject, and no information of an authoritative nature. In that year J. Jettmar published his second edition of *Chromgerbung*, a German work on chrome tanning, which dealt comprehensively and thoroughly with the historical, theoretical and practical aspects of the subject. No translation of this work has been published, although several private translations are in existence. The war broke out, and chrome-tanned leathers, which had hitherto been imported almost entirely, had to be manufactured at home. The dearth of technical literature was felt most keenly, and there was a great demand for any information which could be obtained on the subject. The United Tanners' Federation and the Federation of Curriers, Light Leather Tanners and Dressers took up the question and purchased one of the translations of Jettmar's book immediately after the war. As they were advised that the book was slightly out of date, it was never published, so Mr. Lamb was requested to write a book on this most important subject and thus fill one of the widest gaps in English technical literature to-day.

The present work is the result and is an attempt to combine the theoretical principles underlying chrome tanning with the particulars of some up-to-date practical processes of manufacture. Mr. Lamb claims to be one of the earlier pioneers of the manufacture of chrome leather, having tanned leather by the chrome process so far back as 1895. Since that time he has acted as technical adviser to many of the more important manufacturers engaged in that particular branch of the trade. This work provides the first authoritative information which has been published in England. Mr. Lamb is one of the leading authorities on this subject, and his views will not only be highly respected but will carry great weight.

The information is conveyed in a very easy style, so that not only educated readers may understand it but practical workmen may also grasp its import. The result of this attempt has been very successful, but to the scientific reader there is always a loss. Practical readers will find a good deal of useful information. In turn the processes are all explained as simply and fully as possible, and there is an entire freedom from complex chemical or technical jargon. A series of special chapters is devoted to individual types of chrome leather—*e.g.*, chrome sole, upholstery leathers, box and willow calf and sides, suede calf, suede sheep, glazed kid and patent leathers. Useful appendices are provided giving tables of specific gravities of solutions of various chemicals employed in chrome-leather manufacture, and also a list of dyes particularly suitable for the dyeing of chrome leather. Mr. Lamb is to be congratulated on having made such a valuable contribution to the library of technical works and on having condensed so much valuable information into such a conveniently-sized volume. All interested in the manufacture of chrome leather will be able to glean some fresh information from this work, and it will prove to be a standard work of reference on this subject in both England and America.

D. WOODROFFE

LA TECHNICQUE INDUSTRIELLE DES PARFUMS SYNTHETIQUES. *By* RENÉ SORNET. *Pp.* *x*+135. *Paris: Gauthier-Villars et Cie*, 1923. *Price, paper,* 10 *francs.*

This brochure is one of considerable interest and value to the perfume chemist in particular, and to all interested in the technology of synthetic methods in general. For the chemist who is actually in charge of synthetic manufacturing it will scarcely contain anything new, but even to him it will be a useful *aide-memoire.*

The book is systematised according to the chemical characters of the bodies dealt with, and not in odour classes. Alcohols, Aldehydes, Ketones, Esters, and Bodies of Various Constitutions form the five chapters of the book. The principal substances in each category which are actually manufactured on a commercial scale are alone dealt with. For example, under alcohols we find benzyl alcohol, cinnamic alcohol, phenyl-ethyl alcohol, terpineol and farnesol.

One of the most interesting chapters is that on aldehydes, particularly the preparation of the higher alcohols of the fatty series. This particular group of bodies has come into considerable prominence during the past few years. They possess a most powerful odour and flavour, and unless used in minute amount they absolutely ruin any preparation in which they are used. But when used in very minute amount they impart a distinctiveness to the preparation which renders them absolutely necessary to the up-to-date perfumer and essence maker. Very full and accurate details are given of the manufacture of these aldehydes up to the twelve carbon compounds. There are, however, higher aldehydes than these which have immense value to the essence maker. Amongst the general bodies dealt with, the artificial musks are thoroughly dealt with, as well as such out-of-the-way, but useful, compounds as indol and skatol.

As a short summary of the manufacturing methods employed in the commercial preparation of a very important and interesting group of compounds, the trade in which is rapidly increasing, this little work is to be commended, and any faults are merely those of omission, which the size of the volume renders necessary.

Ernest J. Parry

Gesammelte Abhandlungen. *By* Dr. F. Kehrmann. Vol. II. Part I. Untersuchungen über Hydrochinone und Chinone. Part II. Untersuchungen über Azine und Azoniumverbingdungen. *Pp. viii*+194. *Leipzig: G. Thieme*, 1923. *Price paper*, 8*s*.

This is a companion volume to the one already reviewed in *Chemistry and Industry* (p. 133), and contains reprints of over 100 investigations, embracing a great variety of topics, by Prof. Kehrmann of the University of Lausanne and his collaborators. It is divided into two sections; the first deals with derivatives of quinols and quinones, and the second, which may be regarded as a development of the first, with azine and azonium compounds. These two groups of researches have been carried on simultaneously, during the period 1888 to 1921. It is interesting to learn from the preface that Kehrmann was attracted to the study of quinones and the closely related azine colours by the influence of his teacher, Rudolf Nietzki, who contributed so much to the elucidation of the relation between colour and constitution.

In looking through this substantial volume of researches one is struck by the amount of capable help which Kehrmann was able to command during these busy 30 years, for the number of his collaborators almost equals that of his researches. It would be interesting to know the conditions which enable so much competent assistance to be obtained; for the duties of the professor in a modern English university render such assistance imperative (if much research is to be accomplished), and often difficult to obtain for want of necessary funds. It is impossible to discuss the contents of this volume in anything like an adequate fashion and it will not be attempted. The volume covers a great variety of inquiries, the most important of which are probably those in the second section relating to the preparation and constitution of the eurhodines, indulines, rosindulines, safranines, etc. By a process of synthesis in which ortho-diamines are condensed with a variety of ketones the constitution of the products is made clear, and new methods of obtaining these colouring matters introduced. Much of the work follows the line of investigation which has been pursued with equal success by O. Fischer and Hepp.

J. B. Cohen

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The market continues to be depressed with little business moving. There is no evidence yet of an early return to normal conditions. Prices, however, are well maintained and there are no important changes to report.

Acetic Acid, 40% tech...	£24 per ton. Still firm, but rather less inquiry.
Acid Hydrochloric ..	3s. 6d. - 5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw. ..	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d. - £8 per ton. Demand steady, export inquiry good.
Arsenic (White) ..	About £71 per ton.
Bleaching Powder ..	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Business much below normal.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d. In slightly better demand.
Copper Sulphate ..	£27 per ton.
Potash Caustic	£33 - £34 per ton. Little moving.
Potass. Bichromate ..	5¾d.-6d. per lb. d/d.
Potass. Chlorate ..	3d. per lb. Very dull.
Salammoniac	£32 per ton d/d.
Salt Cake	Home £4 10s. per ton d/d.; Export £5 5s. per ton f.o.b. Export inquiries good with small supply.
Soda Caustic 76% ..	£20 - £21 per ton. Steady demand.
Soda Crystals	£5 5s. - £5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98% ..	£26 per ton. Very scarce for spot delivery.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	2¾d.-3d. per lb. Very dull.
Sod. Nitrate refd. 96%..	£13 5s.-£13 10s. per ton ex Liverpool. Steady demand.

Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	£15-£16 per ton carr. paid. Very quiet. Prices unstable.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7¾d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8¾d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25-£29 per ton according to quantity.
Carbon Black	1s. 1½d.-1s. 3d. per lb. Ample supplies now coming forward.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

There is still a ready market for wood distillation products.

Acetate of Lime—	
Brown	£11 per ton and upwards. Price very firm and demand keen.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8 5s. to £10 15s. per ton, according to locality of market and type of charcoal.
Iron Liquor	1s. 5d. per gall. 32° Tw. Some sales effected at 1s. 7d.
	1s. 2s. per gall. 24° Tw.
Red Liquor	1s. 3d. „ „ 14/15° Tw.
Wood Creosote	2s. 7d. „ „ Unrefined.
Wood Naphtha—	
Miscible	6s. 8d. „ „ 60% O.P. Firm.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5-£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d.-1s. 2½d. per lb. Fair demand.
Crude 60's	3s.-3s. 2d. per gall. Market quiet and uncertain.
Acid Cresylic—97/99	2s.-2s. 5d. per gall. Steady demand.
Pale 95%	1s. 10d.-2s. 4d. per gall.
Dark	1s. 9d.-2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	8¾d.-11d. per gall. Supply short. Plenty of inquiries.
Unstrained	8¾d.-9d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.
Pure	2s. 1½d.-2s. 2d. per gall.
Toluole—90%	1s. 8d.-2s. per gall. Not many inquiries.
Pure	2s.-2s. 4d. per gall. Not much inquiry.
Xylol	2s. 3d. - 3s. 3d. per gall., according to quality.
Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil	8½d.-10d. per gall. Market steady. Good demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.-9d. per gall.
Solvent 90/160	1s. 5d. - 1s. 7d. per gall. Prices slightly weaker.
Solvent 90/190	1s. 4d. - 1s. 7½d. per gall. Very low prices being quoted.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Very little business passing.
Whizzed or hot pressed	£11-£13 10s. per ton. More inquiries.
Naphthalene—	
Crystals	£21 per ton.
Flaked	£17 10s. per ton
Pitch, medium soft	135s.-145s. per ton. Autumn delivery. Market steady.
Pyridine—90/140	18s. per gall. Demand good.
Heavy	8s. - 9s. per gall. Price nominal.

INTERMEDIATES AND DYES

Depression in the textile trade continues, but business in dyestuffs has improved slightly during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 8d.-1s. 9d. per lb. Better demand at reduced prices.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	5s. 3d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Quiet.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb. Fair demand.
p-Cresol 32/24° C.	2s. 1d.-2s. 3d. per lb. Fair demand.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.

p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market remains exceptionally dull and orders continue to be very scarce.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. per lb. for cwt. lots. Market weak.
Acid, Benzoic	2s. 6d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8d. per lb., less 5%. Demand improved.
Acid, Gallic	3s. per lb. Down to 2s. 11d. for large quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d.-2s. 3d. per lb. Limited demand.
Acid, Tannic	3s. 3d. per lb.
Acid, Tartaric	1s. 3½d. per lb., less 5%. Demand improved.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 6d. per lb. wanted for good quality.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz.
Barbitone	21s. per lb. Supplies are short, but in absence of demand price remains unchanged.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Position unchanged. Prices vary according to quantity and source. Market for foreign rather weaker.
Calcium Lactate	2s. 6d. per lb. for best makes. Better demand.
Chloral Hydrate	3s. 9d. per lb., duty paid
Chloroform	2s. 2d. per lb. for cwt. lots. Very dull.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	£96 per ton. Quiet.
Guiacol Carbonate	8s. 6d. per lb. Neglected.
Hexamine	3s. 9d. per lb. In fair supply on a quiet market.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots.
Magnesium Carbonate—	
Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	70s.-80s. per cwt., according to quality and quantity.
Menthol	40s. per lb. spot.
Methyl Salicylate	2s. 4d. per lb. for carboys.
Methyl Sulphonal	15s. per lb.
Morphine	Alkaloid—Cryst. 10s. 11d., Precip. 10s. 8d., Acetate 8s. 6d., Hydrochlor. 8s. 6d. Sulphate 8s. 6d. per oz.
Paraformaldehyde	3s. 9d. per lb. Lifeless.
Paraldehyde	1s. 5d. per lb. Cheaper, with poor demand.
Phenacetin	6s. 6d. per lb.
Phenazone	7s. per lb.
Phenolphthalein	6s. 6d. per lb. Considerably firmer.
Potass. Bitartrate—99/100% (Cream of Tartar)	94s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d. per lb. Good demand. Steady market.
Potass. Permanganate	10½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d. - 2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	5s. 6d. per lb.
Salol	2s. 9d. per lb.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 6d. per lb. Slow of sale.
Sod. Citrate, B.P.C. 1923	2s. 2d. per lb. for cwt. lots.
Sod. Hyposulphite—Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.-87s. 6d. per cwt. Fairly good demand. Expected to improve with continued warm weather.
Sod. Salicylate	Powder 2s. 6d. per lb., and Crystal at 2s. 7d. per lb. Market weaker.
Sod. Sulphite, anhydrous	£27 10s.-£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.
Thymol	15s. 6d. per lb. for cwt. lots of natural recryst.

TRADE NOTES

German Trade and Industry in June

H.M. Commercial Secretary at Berlin reports that the further depreciation of the mark during June induced a strong revival of business in the textile, leather, paper, indiarubber, glass and building industries, and caused exceptional advances in prices, the resulting increases in wages amounting to roughly 60 per cent. Deliveries of coke remained steady in amount, but declined in quality, and production met only the immediate requirements of foundries and gas works. Strikes in the coal districts of Upper Silesia and Waldenburg affected production and the shortage of trucks further hampered delivery. The revival in the sales of potash which occurred during May continued throughout June, the works being in general fully employed; supplies of fuel were adequate, though the quality was unsatisfactory. The strong home demand for chemicals continued, and it was not always possible to carry out orders promptly. Employment in the rubber industry was good, as the home demand was lively and there was a considerable clearance of accumulated stocks.—(*Bd. of Tr. J., July* 19, 1923.)

Trade Information

The Taylor System of Colour Harmony.—We have received a pamphlet relating to the Taylor System of Colour Harmony, which is described as a method for combining colour harmonies with accuracy, ease, speed and certainty. By means of a chart, combinations of two to seven pure different colours can be rapidly selected, as many as 20,000 distinctive combinations being available. The chart, which appears extremely simple to operate, can be obtained from the Taylor System of Colour Harmony, Bedford Row Chambers, 42, Theobald's Road, London, W.C. 1. Pamphlets are supplied which indicate the wide range of applications of the system and explain it in detail.

PUBLICATIONS RECEIVED

LIGHT AND COLOUR. *By* R. A. HOUSTOUN, M.A., D.Sc. *Pp. xi*+179. *London: Longmans, Green and Co.*, 1923. *Price* 7*s.* 6*d.*

THE MINERAL INDUSTRY OF THE BRITISH EMPIRE AND FOREIGN COUNTRIES. COAL AND COKE AND BY-PRODUCTS. *Statistics* 1919–21. *Pp. v*+135. *Imperial Mineral Resources Bureau. H.M. Stationery Office*, 1923. *Price* 4*s.* 6*d.*

AUSKUNFTSBUCH FÜR DIE CHEMISCHE INDUSTRIE *By* H. BLÜCHER. *Vol. I. A—L. Pp. xvi*+840. *Vol. II. M—Z. Pp.* 841—1672. *Berlin: W. De Gruyter and Co.*, 1923. *Price* 11*s. each,* 22*s. the two volumes.*

MANUFACTURED GAS IN THE HOME. *By* S. S. WYER. *The Mineral Industries of the United States. Smithsonian Institution. United States National Museum. Bulletin No.* 102. *Part* 8. *Pp. iv*+24. *Washington: Government Printing Office*, 1923. *Price* 10 *cents.*

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES   LONDON, AUGUST 3, 1923   No. 31

EDITORIAL

IT gives us singular satisfaction to announce an event of some interest, which is besides not without some political significance. The Chemical Society has decided to publish regularly, in *Chemistry and Industry*, abstracts of the papers read before the Chemical Society and the discussions thereon instead of, as heretofore, including these in its Proceedings. These abstracts and reports of the discussions will be supervised by the Chemical Society, and will appear with that authority which such a course confers upon them. Chemists will accordingly be able to peruse in our pages prompt and accurate summaries of these important contributions. We wish to express to the Chemical Society our gratitude for this valuable support, as well as our thanks for the honour they have conferred upon us. Discussions, especially on somewhat controversial matters, are frequently of the utmost value; they bring out new points of view and call attention to facts and ideas which are sometimes half-forgotten or imperfectly interpreted. Some of the old controversial writings are capital reading; the dissertations of Bentley on the Epistles of Phalaris, of Porson on the Three Heavenly Witnesses, and the Provincial Letters of Pascal are as amusing as anyone could wish. Of each of these it might be truly said, "nor could his ink flow faster than his wit"; and in a science growing so rapidly as chemistry there are abundant opportunities for argument. "Where there is much desire to learn, there of necessity will be much arguing, much writing, many opinions; for opinion in good men is but knowledge in the making."

* * *

Glad as we are that our weekly journal of ephemeral matter is in the future to become a means for disseminating knowledge of such importance and permanence, we are perhaps even more impressed by the fact that the Chemical Society, the oldest Chemical Society in the world, and the Society of Chemical Industry, whose activities have hitherto been distinct from those of the senior Society, are now both working together in the publication of chemical information. Perhaps an editor has as good an opportunity as any one of realising the immense number of scientific journals which include chemistry in their scope. Not only in this country, but in other parts of the British Empire and in America, are many journals, some containing original chemical news, and almost all containing epitomes or abstracts of articles appearing in sundry weekly, monthly and quarterly publications. As for the foreign journals, their very names would tire our lazy pen. The system of collecting and distributing this branch of knowledge must be very complete, but to one who has not many occasions for making use of the system, it is not perfectly clear that all the abstracts of the same article are essential. The indexing and the documentation of a rapidly growing science are no doubt necessary; possibly the ideal state of affairs would be that for every country one organisation should ensure that one abstract—and one only—should be prepared of all the papers belonging to some science. Whether the wit of man can devise such an ideal condition we do not know. Perhaps national pride may insist, even then, that the abstracts required by the South of Ireland shall not be prepared by the same individuals who prepare them for Ulster; and that Canada, the United States and South Africa shall make use of separate organisations, each writing epitomes of the same article in the same language. It is, of course, the trifles which are of supreme importance in these things; the principles are so easily adjusted.

* * *

It may be objected that "gas" is an unsuitable subject for an "editorial." Be that as it may, the word represents an investment of many millions of pounds, it lies at the heart of many a domestic problem, and it has recently achieved notoriety as a method of self-destruction. And now no less a body than the Smithsonian Institution (United States National Museum) has published a brochure on "Manufactured Gas in the Home." A glance down the table of contents revealed a fascinating series of titles, just the things one wants to know, such as the effect of a training in home economics on gas consumption, the cost of cooking food with various fuels, the proper way to use gas, and the intriguing heading, "What must happen when gas is burned," followed by its corollary, "What *may* happen when gas is burned." Armed with the information that the gas used to cook a meal for five persons represents under 3 per cent. of the total cost, that the maximum temperature required by cooking operations is always below 500° F., and that "generally much more gas is used than is needed for various cooking operations," we obtained half-hearted permission to investigate the domestic laboratory of a friend. Quoting the brochure, we said :—"The heat that does useful work must not be merely delivered into the cooking vessel, but must actually penetrate and get into the food," and then put a series of questions, of which the following are typical :—"What kind of lagging do you prefer for gas ovens ?" What is your opinion of the relative thermal conductivity and resistance to organic matter of nickel and aluminium ? Discuss the merits of Prof. Bone's Radiophragm." After a withering request to speak plain English, we were asked to go. As we left we noticed the absence of thermometers, balances, racks, and other commonplaces of the chemical laboratory. Yet delicate operations such as the pasteurisation of milk, the preparation of colloidal pastes containing carbonates, organic acids, synthetic organic chemicals such as vanillin, etc., were carried on, apparently with success. Such success, it seems, that although the industrial case-hardening of steel requires close scientific control, yet case-hardening can be applied daily to food with unfailing ease and regularity by care-free empirics. It is a very serious problem, of immense importance to national health and economy, and it is at least paradoxical that a chemist who controls a plant turning out large quantities of a product 99·98 per cent. pure from materials of known composition, will attack his evening meal without the slightest thought of fuel economy, of purity of raw materials, of corrosion, or other problems that occupy him during the day. Such a state of biochemical knowledge is serious, and we hope that a day will come when Prof. Gowland Hopkins will have students who will investigate the heat treatment of viands or isolate the succulent principle of the prawn. Owing to the national habit of mind the problem is obscured by frivolous associations, but we are intensely serious in our hope that some of our chemists will be stimulated to investigate several of those unsolved problems that few are lucky enough to ignore.

THE EXISTENCE OF AMMONIUM HYDROXIDE IN SOLUTION

By Prof. R. M. CAVEN

In reply to Prof. Moore's second article on the Existence of Ammonium Hydroxide in Solution (*Chemistry and Industry*, 1923, p. 641), I wish first to deal with specific criticisms of my previous articles (*ibid*, 1923, pp. 164 and 448), and then to summarise the evidence and arguments upon the subject as they present themselves to me.

1. Prof. Moore seems to regard the temperatures of rapid loss of water by salts of the type $CuSO_4,M_2SO_4,6H_2O$ as evidence of equal value to the vapour pressures developed by these hexahydrates in equilibrium with the corresponding dihydrates. I can only say that the vapour pressures determined by Ferguson and myself represent a true equilibrium attained both in the course of raising the temperature and of lowering it, and that we have found by experience that unless care is taken to add some of the corresponding dihydrate before the experiment is commenced erratic results even for vapour pressures are obtained. There is no doubt that the order of alkali metals established by us, agreeing as it does with that discovered by Tutton for a different class of phenomena, represents truly the power of retaining water which the alkali metals, including the ammonium radicle, confer upon the copper sulphate in the double salt ; and so the only conclusion I can draw from the fact that as regards free loss of water the ammonium double salt is out of order is that this salt does not assume a metastable state when heated as some of the others seem to do. In this respect ammonium appears to precede instead of to follow rubidium in the series of alkali metals, but I do not know what significance to attach to so obscure a phenomenon.

2. Then, as regards the temperatures of rapid dehydration of the dihydrates, Prof. Moore seeks to show from our figures that the same order of alkali metals is not maintained in the affinity of the double salts for water. As I have already stated, his argument is vitiated by the fact that a true equilibrium is not established when a hydrated salt is heated in an open space or left in a vacuum over sulphuric acid. It does not follow, however, that the same order of alkali metals is to be expected here. In the double salts $CuSO_4$, M_2SO_4, $6H_2O$, which are derivatives of the extremely unstable $CuSO_4$, $7H_2O$, the function of the alkali metal indicated by vapour pressure is that of enabling the copper sulphate to retain a larger proportion of water than it could alone, as in the salt $CuSO_4$, $5H_2O$. This is not the case with the dihydrates $CuSO_4$, M_2SO_4, $2H_2O$, which are derivatives of stable $CuSO_4$, $3H_2O$. It may be, therefore, that different conditions obtain here ; but we must wait and see. In any case, I do not admit the propriety of drawing

general conclusions in anticipation of the facts.

3. When Prof. Moore cites phenomena of solubility to show that ammonium is out of order, he ventures on to treacherous ground; for anyone who tries to generalise from these phenomena will meet with what appear, from our limited knowledge, to be baffling inconsistencies. To show this, ammonium may be left out of account, and the salts of the alkali metals potassium, rubidium, and cæsium be considered. As regards the chlorides, the order of increasing solubility is K, Rb, Cs, whilst with the platinichlorides the reverse order Cs, Rb, K obtains; with the sulphates the order is again K, Rb, Cs, and with the alums the reverse order Cs, Rb, K. It seems, therefore, as if a generalisation might be made here as regards the reciprocal relations of single and complex or double salts; but on further examination this generalisation is upset, for the order of solubility of the nitrates is Cs, K, Rb, whilst the solubilities of the salts at present under consideration, viz. $CuSO_4$, M_2SO_4, $6H_2O$, determined by Locke (*Amer. Chem. J.* 1902, 27, 459) are as follows: I litre of water at 25° dissolves of the anhydrous salts:—

	K	Rb	Cs
Grams ..	116·9	102·8	460·0
Moles. ..	0·350	0·241	0·883

If, therefore, such inconsistencies are found with regard to the solubilities of salts of the alkali metals concerning whose electropositiveness there is no dispute, of what use are these phenomena in deciding the position of ammonium, or controverting conclusions drawn from other phenomena?

4. Now, with regard to the quotation from Holleman, I must confess that my critics, Mr. F. B. Finter and Dr. A. E. Clarence Smith, as well as Prof. Moore, are right; for Holleman errs in attributing strict neutrality to a solution of ammonium chloride. It is interesting and satisfactory to recognise, as Prof. Moore points out, that the degree of so-called hydrolysis of ammonium chloride is what might be expected from the low hydroxidion concentration of dilute ammonia solution. If, however, Prof. Moore will refer again to my first article in *Chemistry and Industry* (1923, p. 165, lower part of second column), he will find that the validity of my argument is not affected by the fact that ammonium salts develop acidity in solution; for the latter, as well as the basic weakness of ammonia solution, is attributable to the instability of NH_4, which breaks down in solution into neutral NH_3 and $H^{\cdot}$. I may, however, repeat that "this reaction is not really hydrolysis, since water does not act chemically on the salt," and also that the powerful electropositiveness of ammonium is not incompatible with its instability.

5. I now offer the following summary of the subject:—Suppose the salts of an unknown basic radicle are being examined. It is found that these salts closely resemble those of potassium, and particularly it is observed that the solid hydrogen-sulphate and hydrogen-carbonate of this radicle exist. Since it is only the strongest metals which form the latter salts it is concluded that the radicle forming them must, by reason of its basigenic strength, be placed among the alkali metals. Then it is observed that, according to the accumulated results of Tutton's measurements upon double hydrated salts in which this radicle occurs, supported by the measurements of vapour pressures by Caven and Ferguson, the unknown radicle takes a place in the series of the alkali metals near to rubidium.

If that were all the evidence the basigenic strength of the radicle would not be called in question. When, however, salts of the radicle are heated with aqueous alkali, ammonia gas is evolved, and the solution of this ammonia in water behaves as a feeble base. Moreover, not only is the hydroxidion concentration of dilute ammonia solution very small, but there is found to be present in the liquid, according to the experiments of Moore and Winmill, a large proportion of a compound having the empirical composition NH_5O, which is reasonably believed to be ionisable ammonium hydroxide. Thus, there seems good reason to account for the basic weakness of dilute ammonium solution; viz., ammonium hydroxide is a weak base which is very imperfectly ionised in aqueous solution.

It must be pointed out, however, that the physical measurements employed are necessarily static; *i.e.*, they reveal the state of the ammonia solution and not the potentiality of the compound NH_5O. Whether this compound is ionisable or not, whether it is NH_4OH or $NH_3.H_2O$ is not revealed. This fact is now admitted by Prof. Moore. Therefore, we are open to consider an alternative explanation of the alkalinity of ammonia solution; which is the explanation of Lowry that NH_3 and not NH_4OH is the base; that the course of reaction of NH_3 with water is:—

$$NH_3+H^{\cdot}+OH' \rightleftarrows NH_4^{\cdot}+OH'$$

and not $NH_3+H_2O \rightleftarrows NH_4OH \rightleftarrows NH_4^{\cdot}+OH'$;

to which, however, must be added the reaction established by Prof. Moore:

$$NH_3+H_2O \rightleftarrows NH_5O.$$

The reason why I prefer the view of Prof. Lowry to that of Prof. Moore is that, whilst it seems to account equally well for the properties of solutions of ammonia and of ammonium salts, it also accounts for the properties of solid salts containing ammonium, because it makes credible the belief that the radicle ammonium is strongly basigenic though somewhat unstable.

Finally, I submit that the view I have adopted, following Prof. Lowry, is simpler than that which assumes the formation and subsequent ionisation of ammonium hydroxide; and I suggest that if we began to theorise afresh upon this subject, free from the preconception of an alkali hydroxide as a compound whose atoms are united by chemical bonds of the old-fashioned kind, which somehow break asunder when the compound is dissolved in water, we should not create the fiction of an imperfectly ionised ammonium hydroxide to explain the properties of ammonia solution and ammonium salts; and this partly because the theory is inadequate, leaving the properties of solid ammonium salts unaccounted for, and partly because it is superfluous.

It is unscientific to harbour a theory which is superfluous as well as inadequate; and therefore this discussion leaves me convinced that the views set forth in my first article are substantially correct.

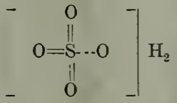
Royal Technical College,
Glasgow

OLD AND NEW THEORIES OF CO-ORDINATION

By Prof. T. MARTIN LOWRY, F.R.S.

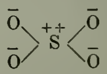
1. The appearance of an English translation of a post-war book on co-ordination* provides an opportunity of comparing the position of the theory as Werner bequeathed it to us, with the newer aspects which have been developed by Langmuir, Sidgwick and others on the basis of the electronic theory of valency. As regards the original theory of Werner, it is impossible to estimate too highly the value of his conceptions in clarifying a vast range of obscure phenomena. The successive step by which he established the octahedral configuration of the six co-ordinated groups, first by demonstrations of stereoisomerism, and then by the unshakeable evidence of optical activity, will always rank amongst the classics of chemical science. This impression of the masterly character of Werner's work is maintained on going through the theory as expounded by Professor Schwarz; but certain aspects of the theory are felt to be unsatisfactory in the light of the clearer views which are now available as to the nature of valency. Some of these are referred to in the following paragraphs.

2. The conception of auxiliary valency, which lies at the base of the whole theory of co-ordination, is too vague to bear strict criticism. In the earlier chapters of the book, the impression is obtained that these auxiliary valencies differ in character from the principal valencies, and one is led to anticipate that they will be definitely weaker. Thus, the author represents the combination of sulphur trioxide and water to form sulphuric acid by means of the formula



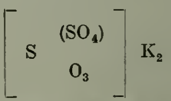
$$\left[\begin{array}{c} O \\ \| \\ O{=}S{\cdots}O \\ \| \\ O \end{array}\right]H_2$$

in which the first three oxygens are held to the sulphur by pairs of principal valencies, whilst the fourth is held only by a single auxiliary valency, represented by a series of dots. This discrimination between the four atoms of the sulphate ion is, however, entirely unjustified; and, indeed, in a later paragraph it is admitted that "no real difference between principal valencies and auxiliary valencies is found to exist in complex nuclei." The electronic formula for the sulphate ion which can be represented by the conventional formula



is free from this ambiguity.

3. A similar difficulty arises in reference to the acids, such as $H_2S_2O_7$, $H_2Cr_2O_7$, etc., which Professor Schwarz calls "isopolyacids." The idea of representing potassium pyrosulphate by the unsymmetrical formula



$$\left[\begin{array}{cc} & (SO_4) \\ S & \\ & O_3 \end{array}\right]K_2$$

is obviously without justification. The conventional formula $KO\cdot SO_2\cdot O\cdot SO_2\cdot OK$, which can readily be expressed in terms of electrons, is much more in accord with the origin and behaviour of the compound. Since each sulphur is still surrounded by four oxygen atoms, the conditions for co-ordination are satisfied, although one oxygen atom must belong to both co-ordination spheres, thus

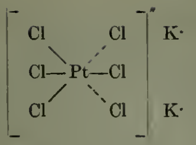
$$\overbrace{K[O\cdot SO_2\cdot[O]}\underbrace{SO_2\cdot O]K}.$$

The polychromates and polysilicates can also be represented better by the traditional formulae than in terms of the co-ordination-theory, which contributes little or nothing to their elucidation. On the other hand, the 42 oxygen atoms which are characteristic of the phosphomolybdates and allied compounds, whether they contain 7, 8 or 9 ionisable hydrogen-atoms, find for the first time a clear interpretation in the theory of co-ordination.

4. Another point of ambiguity in the theory of co-ordination is in reference to the localisation of the electric charges on the complex ion. Prof. Schwarz writes the constitutional formula of potassium platinichloride as

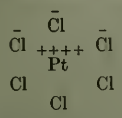
---

* *The Chemistry of the Inorganic Complex Compounds.* An Introduction to Werner's Co-ordination Theory. By Robert Schwarz. Authorised Translation by Lawrence W. Bass, Ph.D. Pp. x.+82. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1923. Price 8s. 6d. net.

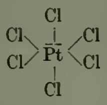


He assumes that four of the chlorine atoms are attached to platinum by principal valencies, and two by subsidiary valencies; and that since the principal valencies of the last two chlorine atoms are unsaturated, the two potassium atoms may attach themselves at these points. Here again the discrimination between principal and auxiliary valencies cannot be maintained; and a much clearer picture results from the view that the quadrivalent platinic ion begins by attracting to itself six chlorine ions as in I (compare this vol., p. 316), and then draws into its outer shell a pair of electrons from each chlorine ion giving rise to a covalent structure as in II (this vol., p. 412):

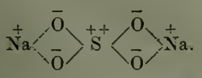
I



II



In this case, since the platinum (recalling the familiar definition of an island) is "entirely surrounded by chlorine" the orientation of the two potassium ions in the undissociated salt is probably determined by crystallographic considerations based upon the close-packing of ions. In the case of the sulphates, however, the metallic kations may well be associated definitely with the negatively-charged oxygens of the quadripolar ion, thus



5. Water of crystallisation is always a source of difficulty to the advocate of co-ordination, since the formation of hexahydrates is by no means universal. The suggestions (i) that the heptahydrates contain one unco-ordinated molecule of water, and (ii) that the alums contain co-ordinated double-molecules, H_4O_2, in a complex ion $[Al{\cdot}6H_4O_2]$, are too artificial to be accepted without further independent evidence in favour of these assumptions; but it is curious that no attempt is made to show some of the surplus molecules of water as associated with the sulphate ion, since the sulphates are practically unique in forming this particular series of hydrates. A clear distinction between crystalline hydrates and hydrated ions of sufficient stability to persist even in solution would be of value; but this will be much more difficult to realise than in the case of the ammines, since the experiments ought obviously to be made in some non-aqueous solvent, such as anhydrous liquid ammonia.

6. The distinction, made by Werner, between ionisable and non-ionisable valencies is unsatisfactory. In cases such as KCl, $BaCl_2$, etc., it is clear that "principal valencies" are ionisable; but it is equally clear that in CCl_4 they are not. The idea that "ionisable chlorine" means chlorine held by principal valencies is therefore incorrect; and the converse idea, that chlorine united directly to the metal is not ionisable, is scarcely tenable in the case of a salt such as KCl, which is an excellent electrolyte when merely melted. Sidgwick's view that non-ionisable complexes are held together by covalencies is much more satisfying, especially when combined with the further suggestion that the rupture of a weak covalency may at any moment convert it into an electrovalency. The idea that the ions of aqueous electrolytes are pushed apart and finally detached from one another by the intrusion of co-ordinated molecules of water may, however, be put forward as an interesting variant on the hydrate theory of ionisation (*Trans. Faraday Soc.*, 1905, 1, 197; 1907, 3, 132).

7. The translation has been done so well that the book bears no traces of its alien origin. It is issued in a very attractive form, and can be strongly recommended to students who wish to become acquainted with this most fascinating branch of chemistry.

THE NEW "KENNEDY" OIL METER

(From a Correspondent)

There has just been placed on the market by Messrs. Glenfield and Kennedy, Ltd., Kilmarnock, a new pressure meter for the measurement of oil, especially in connexion with oil tankers and oil storage plant generally. As is well known, Messrs. Glenfield and Kennedy for over fifty years past have supplied meters of every description for many kinds of liquid.

The new meter for measuring oil of almost any viscosity, is an adaptation of the "Kennedy" hot-water pressure meter, and is of the displacement type. It consists essentially of a vertical cast-iron measuring cylinder fitted with a metallic piston and cast-iron cover. Each complete stroke of the piston, actuated by the pressure of the oil from the pump used in causing oil to travel, corresponds to the displacement of a definite and measured volume of oil. The mechanism of the meter is double acting and automatically reversing, and each stroke of the piston is recorded in terms of gallons of oil by means of a train of wheels or a series of graduated dials.

The piston is of cast iron, with two special gunmetal piston rings, and the cylinder is machined out internally so as to give a smooth bore and form a perfectly tight joint. To the end of the piston rod, passing through a stuffing box in the cover, is attached a rack which engages in a pinion, and operates both the recording mechanism and also the reversing arrangement, which automatically ensures that the meter is double acting and the flow of oil is alternately under and over the piston, as required, at the end of the stroke. It should be noted that the measuring mechanism is continuous in action, that is to say, it does not measure merely the number of separate strokes of the piston, but the continuous travel, a much more accurate arrangement.

The meter is made in standard sizes of 3 in. to 8 in. bore. A 6 in. meter is a useful unit for oil tanker work, and handles normally 16,000 gallons of oil per hour, with an overload capacity of 25,000 gallons, and the net weight is 2966 lb. or 3080 lb. with packing, the latter being a case 60 in.+39 in.+$37\frac{1}{2}$ in. The meter is tested to 500 lb. pressure, and if provided with a gunmetal cylinder liner can also be used for hot water under pressure, or for liquids like petrol, benzol, and alcohol. The loss of pressure on the pump circuit is very small, and depends, of course, on the viscosity of the oil. When using water at 60° F. the loss caused by a 6 in. meter or the normal duty of 16,000 gallons per hour is only $2\frac{1}{2}$ lb. per square inch, and with an ordinary crude petroleum fuel oil at 60° F. the figure is about 8 lb. per square inch. Very thick viscous oils, almost like greases, can also be measured with perfect accuracy, provided the necessary extra power in the pump is available, equivalent to, say, 50-100 lb. per sq. in.

THE ARTIFICIAL SILK INDUSTRY

Reports from Lyons state that the brisk demand for artificial silk keeps the factories fully occupied, so that many cannot accept new orders until a certain period has elapsed. Statistics are appended showing the world production in 1922, according to an estimate prepared by the American Viscose Co., revised figures calculated by the *Bulletin des Soies et des Soieries*, of Lyons, on the basis of the daily output being given in parentheses :—

	Kg.	
United States ..	10,645,500	
England	6,949,020	(2,038,500)
Germany	5,700,552	(4,756,500)
Belgium	2,850,276	(3,397,500)
France	2,850,276	(4,077,000)
Italy	2,850,276	(2,718,000)
Holland	1,140,110	(543,600)
Switzerland	855,052	(2,718,000)
Hungary	855,082	
Austria	712,569	
Poland	427,541	(271,800)
Czechoslovakia ..	285,027	
	36,121,284	

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS

The Society of Chemical Industry has in each of the past two years held a dinner in London in the month of October, but for the present year arrangements have been made for an Informal Dinner and a Social Gathering of Chemists under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry, which members of these, and of any other of the Chemical Societies, with their friends (including ladies) may attend.

This dinner will be held in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on the evening of Wednesday, October 31, at 7 for 7.30. The price of tickets for ladies or gentlemen will be 12s. 6d. each, not including wine.

Further particulars will be issued later, and the Councils hope that Members of the Societies mentioned, who intend to be present, will make early application for tickets, which must be limited to 300. These will be issued in the order in which applications accompanied by payment are received.

Applications should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2.

ADVANCE PROOFS OF PAPERS

Authors of papers which are to be read before local sections or groups, may in some cases desire to have a few advance proofs for distribution among those likely to make useful contributions to the discussion. Any author who requires such advance proofs is requested to hand the manuscript of his paper to the Local Secretary so that it may reach the Editor at least *one month* before the date of the meeting at which it is to be read, in order to allow sufficient time for it to be considered by the Publications Committee and, if approved, set up in type.

ANNUAL REPORTS

Vol. VII. is now ready and can be obtained by members at the price of 7s. 6d., post free, from the offices of the Society.

DEATH

Kuttroff, Fred (elected 1900), of 128, Duane Street. New York City, U.S.A., Merchant. On October 22, 1922.

SOCIETY OF GLASS TECHNOLOGY

During the visit of over 30 British members of the Society of Glass Technology and their friends to France during the first week of July, two meetings with French glass manufacturers were held on July 2. In the morning, the party was received by the Chambre Syndicale des Maîtres Verreries, and was welcomed by its president, Monsieur L. Houdaille, who said that French glass manufacturers were all united in one body—the Chambre Syndicale—which was divided into six sections representing various branches of the industry. These sections were organised in such a way as to prevent ruinous competition between members, whilst encouraging individual research and development. Monsieur L. Delloye spoke of the need for co-operation among manufacturers of different countries, and Prof. W. E. S. Turner, Col. S. C. Halse and Mr. E. A. Hailwood replied for the Society of Glass Technology.

In the afternoon (after a lunch at which visiting members were the guests of the Chambre Syndicale des Maîtres Verreries), a joint meeting was held with the Société des Ingénieurs Civils. In the absence of Monsieur Guillet, President of the Société des Ingénieurs Civils, Monsieur L. Delloye welcomed the visitors. The following papers were communicated :—(I) Prof. H. Le Chatelier : " La Méthode Scientifique dans L'Industrie." (II) Dr. A. Granger : " Les Verres Opaques et Colorées, et les Glaçures Céramiques de Même Espèce." (III) Mons. Lafon : " La Dilatation des Verres et Cristaux." (IV) Prof. W. E. S. Turner : " Specifications for Glass Products." (V) Mr. T. Teisen : " Improvements in the Design of Recuperative Glass Pot Furnaces." (VI) Mr. S. English and Prof. W. E. S. Turner : " The Physical Properties of Boric Oxide Glasses."

During the week visits were paid to the following glass works :—Etablissements Legras at St. Denis, Verreries de Reims (Messrs. Charbonneaux & Cie.), the plate-glass works at Chantereine, and the Glaceries de St. Gobain, Chauny and Cirey. Members took the opportunity when at Reims of visiting the battlefields in that district. A visit was also paid to the sand quarries at Nemours and to Fontainebleau. Amongst other social activities, a complimentary dinner was given by the visiting party to Monsieur L. Delloye, who had made all the arrangements in France. At Noyon the party was entertained to lunch by the directors of Les Glaceries de St. Gobain, Chauny and Cirey. A reception was also given to the visitors by Monsieur G. Despret (Administrateur des Verreries de Boussois), Paris, when an interesting exhibition of artistic glass was on view. It will be recalled that a party of members of the Society visited America in 1920, and owing to the success of both these visits it is proposed to arrange other tours as opportunity arises.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

The meeting held on June 27 by the Fuel Group was devoted to the presentation of a paper by Monsieur E. Audibert (director of the experimental station of the Central Committee of the French Coal Mines) on " Coal and the Liquid Fuel Problem."

After briefly sketching the history of the subject, the author showed that the consumption of petroleum followed a steep ascending curve. In 1922, out of a production of 120,000,000 metric tons of petroleum, the United States produced 68 per cent., Mexico 27 per cent., and Europe 7 per cent., but the United States, although the largest producer, was also the largest importer and consumer, its consumption having increased from 18,000,000 barrels in 1913 to 125,000,000 barrels in 1921. M. Audibert estimated the world's reserves of petroleum at roughly 10 milliard tons and suggested that all the petroleum would be exhausted in the year 2000, whereas the reserves of coal would probably last for 70 centuries. France possessed practically no petroleum and so had to import large quantities (725,000 m.t. in 1921). Consequently, close attention had been devoted to the synthesis of petroleum, starting from coal or other products, and to the use of alcohol as a national fuel.

In discussing the direct transformation of solid fuels into petroleum, the speaker recalled the process introduced 50 years ago by Berthelot, for hydrogenating many hydrocarbons and even coal, which gave yields of as much as 60 per cent. of petroleum. Recently, Bergius had re-examined the question, using hydrogen at 400° C. under a pressure of 40 to 200 atmospheres, and obtained a good yield from coal, provided that it contained less than 80 per cent. of carbon. Bergius was now working on a continuous process, in which coal dust was suspended in oil, and yields of 80 per cent. had been obtained from coal at the Kaiser Wilhelm Institute, using nascent hydrogen derived from the decomposition of sodium formate. The tars produced by the low-temperature distillation of coal could also be hydrogenated catalytically ; naphthalene could be transformed by the Sabatier process into tetralin or decalin ; and phenols could be converted into liquid fuels, such as cyclohexanol, etc. Tars produced by the high-temperature distillations of coal could also be hydrogenated, and methane from coke-oven gas could also serve as a source of alcohol or hydrocarbons.

Recent deaths in the United States include those of A. T. Beach, president of the Abbé Engineering Co., and of J. van Vorst Booraem, consulting engineer and sugar manufacturer.

CORRESPONDENCE

THE COMBUSTION OF NITROGEN UNDER HIGH PRESSURES

Sir,—Prof. Bone's contribution to the Royal Society in regard to his experiments on the "Influence of Nitrogen on Combustion of Carbon Monoxide" prompts me to refer to previous experiments which satisfactorily confirm Prof. Bone's conclusions in regard to the differences in the influence of hydrogen and carbon monoxide upon the combustion of nitrogen. I have already referred to these phenomena in 1912 (*Mitteilungen über Forschungsarbeiten*, 1913, *Heft* 133 *u. Zeitschrift des Ver. Deut. Ing.*, 1912, p. 1157) and subsequently in abstract form (this *J.*, 1922, 253 R). The tests showed, for example, that with mixtures of carbon monoxide and air the formation of nitrogen oxides was between 25 and nearly 100 per cent. greater than in the case of mixtures of coal gas and air, and this in spite of the fact that the relevant conditions, viz., explosion pressure, explosion temperature and nitrogen content were practically identical, and that the difference in the oxygen content was insufficient to explain the considerable difference in the formation of nitrogen oxides which resulted. The coal gas used contained approximately 48 per cent. of hydrogen. At that time (1912), I sought to find an explanation for this result in photochemical reactions occurring in the exploding gas mixture. Thus a striking relationship is observed between the duration of the maximum temperature and the quantity of nitrogen oxides formed, and this may be exemplified by the following figures, in which the nitric-oxide concentration for purposes of comparison has been recalculated in accordance with the law of mass action to the same oxygen content in the explosion mixture :—

Nitric oxide concentration in exploded gas mixture in vol. per cent.	0·41	0·65	0·80
Duration of maximum temperature of explosion in seconds ..	0·002	0·010	0·025
